# Contents

Foreword – Franz E. Weinert	xi
Preface	xv
<b>PART I CHANGING CONCEPTIONS OF GIFTEDNESS AND TALENT</b>	
1. Conceptions of Giftedness from a Meta-Theoretical Perspective Albert Ziegler and Kurt A. Heller	3
2. A History of Giftedness in School and Society Abraham J. Tannenbaum	23
3. Giftedness as Developing Expertise Robert J. Sternberg	55
4. Understanding the Complex Choreography of Talent Development Through DMGT-Based Analysis Francoys Gagné	67
5. New Conceptions and Research Approaches to Creativity: Implications of a Systems Perspective for Creativity in Education Mihaly Csikszentmihalyi and Rustin Wolfe	81
6. Giftedness in Non-Academic Domains: The Case of the Visual Arts and Music Ellen Winner and Gail Martino	95
7. Genius and Giftedness: Same or Different? Dean K. Simonton	111
8. International Trends and Topics of Research on Giftedness and Talent Kurt A. Heller and Neville J. Schofield	123
<b>PART II DEVELOPMENT OF GIFTEDNESS AND TALENT</b>	
1. Developmental Psychology and Giftedness: Theories and Research Franz J. Mönks and Emanuel J. Mason	141
2. Genetic Tools for Exploring Individual Differences in Intelligence Lee A. Thompson and Robert Plomin	157
3. Giftedness, Expertise, and (Exceptional) Performance: A Developmental Perspective Wolfgang Schneider	165

4.	Issues in the Cognitive Development of Exceptionally and Profoundly Gifted Individuals Miraca U. M. Gross	179
5.	Motivation and Cognition: Their Role in the Development of Giftedness Willy Lens and Per Rand	193
6.	Social-Emotional Development and the Personal Experience of Giftedness Laurence J. Coleman and Tracy L. Cross	203
7.	A Life Span Approach to Talent Development Ingrid Schoon	213
8.	Prodigies, Savants and Williams Syndrome: Windows Into Talent and Cognition Martha J. Morelock and David Henry Feldman	227
9.	Addressing the Most Challenging Questions in Gifted Education and Psychology: A Role Best Suited to Longitudinal Research Rena F. Subotnik and Karen D. Arnold	243
10.	A 'Talent' for Knowledge and Judgement about Life: The Lifespan Development of Wisdom Monisha Pasupathi and Ursula M. Staudinger	253

### **PART III IDENTIFICATION OF GIFTEDNESS AND TALENT**

1.	Identification of Gifted and Talented Youth for Educational Programs John F. Feldhusen and Fathi A. Jarwan	271
2.	Dynamic Assessment of Gifted Students Lannie Kanevsky	283
3.	Early Identification of High Ability Christoph Perleth, Tanja Schatz and Franz J. Mönks	297
4.	Prediction of Excellence in School, Higher Education, and Work Günter Trost	317

### **PART IV GIFTED EDUCATION AND PROGRAMMING**

1.	Conceptual Foundations and Theoretical Lenses for the Diversity of Giftedness and Talent LeoNora M. Cohen, Don Ambrose and William N. Powell	331
2.	Theory and Research on Curriculum Development for the Gifted Joyce VanTassel-Baska	345
3.	The Schoolwide Enrichment Model Joseph S. Renzulli and Sally M. Reis	367

---

4.	Instructional Psychology and the Gifted Hans Gruber and Heinz Mandl	383
5.	The Education and Development of Verbally Talented Students Paula Olszewski-Kubilius and Samuel P. Whalen	397
6.	Nurturing Talents/Gifts in Mathematics Wilhelm Wiczerkowski, Arthur J. Cropley and Tania M. Prado	413
7.	Talent Development in Science and Technology Michael C. Pyryt	427
8.	Promotion of the Gifted in Vocational Training Rudolf Manstetten	439
9.	Giftedness: The Ultimate Instrument for Good and Evil Abraham J. Tannenbaum	447
10.	New Trends in Research on Moral Development in the Gifted Adriano Pagnin and Ornella Dentici Andreani	467
11.	Programs and Strategies for Nurturing Creativity Arthur J. Cropley and Klaus K. Urban	485
12.	Developing Gifted Programs Sidney M. Moon and Hilda C. Rosselli	499
13.	Academic Competitions and Programs Designed to Challenge the Exceptionally Talented James Reed Campbell, Harald Wagner and Herbert J. Walberg	523
14.	Evaluation as a Critical Component of Program Development and Implementation Carolyn M. Callahan	537
15.	Cross Cultural Studies in Gifted Education Edna Leticia Hernández De Hahn	549
<b>PART V COUNSELING AND NURTURING GIFTEDNESS AND TALENT</b>		
1.	Global Professionalism and Perceptions of Teachers of the Gifted Alexinia Y. Baldwin, Wilma Vialle and Catherine Clarke	565
2.	Families: The Essential Context for Gifts and Talents Joan Freeman	573

---

3.	Identifying and Educating Poor and Under-Represented Gifted Students James H. Borland and Lisa Wright	587
4.	Counseling Gifted Students Nicholas Colangelo and Susan G. Assouline	595
5.	Underachievement in Gifted Children and Adolescents: Theory and Practice Willy A. M. Peters, Helga Grager-Loidl and Patricia Supplee	609
6.	Attention Deficit/Hyperactivity Disorder in Gifted Students Felice A. Kaufmann and F. Xavier Castellanos	621
7.	Gender Differences in Engineering and Physical Sciences Among the Gifted: An Inorganic-Organic Distinction David Lubinski, Camilla P. Benbow and Martha J. Morelock	633
8.	Guiding Gifted Girls and Young Women Barbara Kerr	649
9.	Inclusive Education for Gifted Students with Disabilities Carolyn Yewchuk and Judy Lupart	659

## **PART VI EXAMPLES OF COUNTRY EFFORTS, POLICIES, PROGRAMS AND ISSUES**

1.	National/Provincial Gifted Education Policies: Present State, Future Possibilities Rose A. Rudnitski	673
2.	Changing Paradigms for Gifted Education in the United States James J. Gallagher	681
3.	A Study of Education for High Ability Students in Canada: Policy, Programs and Student Needs Janice A. Leroux	695

# Foreword

Franz E. Weinert

*Max-Planck-Institute for Psychological Research, Munich, Germany*

Most scientists do their work in seclusion, and only a small circle of experts is interested in their theoretical questions, methodological advances, and empirical findings. In contrast, like research on molecular genetics or communication technology, even small-scale scientific studies and local innovations leading to a better theoretical understanding, early identification, and specific promotion of gifted and talented individuals enjoy an international reception and discussion. This public interest has grown significantly in recent years and will probably continue to grow in the future. There are several reasons for this.

Talented individuals are nature's gift to society; this idea from Karl Marx reflects an intuitive belief shared by many persons across various cultures throughout history. In the past, persons with exceptional abilities and achievements were admired, honored, but also often feared and sometimes even persecuted. There have been hardly any changes in attitudes toward the phenomenon of giftedness right up to the present day. However, what has changed dramatically is the awareness of how important the gifted are for cultural progress, scientific innovation, and economic prosperity.

In an age of advancing globalization and continued international competition, the focus is no longer on the myth of individual genius, but on the identification and education of as many gifted children and adolescents as possible. The last few decades have seen a remarkable expansion of the arts, science, technology, business, and political administration throughout the world. This has been accompanied by continuing differentiation and specialization in job demands. Although the scientific production of new knowledge is advancing rapidly, this has not been accompanied by any decline in the amount and difficulty of problems to be solved. Demanding intellectual, personal, and social challenges can be found wherever one looks. There is a continuously growing need for gifted, creative, and talented persons to acquire specialized expertise and achieve high levels of performance and responsibility. This is why it is not surprising that research on giftedness receives so much public attention and is the focus of a variety of interests:

(1) International organizations (such as the United Nations, OECD) hope that the identification, psychological encouragement, and systematic training of the gifted will improve economic and social conditions in not only the industrialized, but, above all, the Third World and lead to a reduction in political tensions and conflicts.

(2) National, regional, and local administrations are initiating special programs for gifted children because they anticipate long-term advantages in terms of national and international competitiveness. There is an increasing awareness in many countries that human abilities and talents are one of the most important resources for future growth. Such administrations are seeking—often in desperation—a scientific orientation for their programs as well as professional evaluation.

(3) In the 1960s and 1970s, most educational institutions in the industrialized world—alongside their underlying philosophies and theories of education—went beyond their general tasks and focused on the problems of socially and intellectually disadvantaged children. Numerous programs were developed for them. Nowadays, there is a broad consensus that not only children with learning difficulties but also gifted children require special education lest they fail to live up to their promise. This has led to the emergence of numerous special schools, school classes, programs, and projects for gifted students in recent years. The practical experiences thus gained represent important sources for improving our understanding of gifted and talented students and designing more appropriate interventions.

(4) Scientists from many disciplines (e.g. differential psychology, cognitive psychology, developmental psychology, educational psychology, social psychology, human genetics, sociology, and educational science) have not only contributed to the current knowledge on giftedness but also pursue research in this field from different theoretical perspectives and with a lively critical interest. At the present time, despite a research tradition going back more than 100 years, we cannot assume a shared corpus of confirmed knowledge. Instead, there are various,

sometimes competing, theoretical, methodological, and educational approaches that each have to be judged with different sets of criteria.

(5) Parents who have, or believe they have, gifted children naturally exhibit a strong interest in those results of psychological research that possess practical relevance, in the instruments developed to identify gifted individuals, and the special education opportunities (or even needs!) of daughters and sons whose accelerated development often deviates from their peers. Such parents expect science to assist them in solving their problems. However, they also want to cooperate with scientists and often become committed and critical participants within the system of local or national programs for the gifted.

(6) Gifted children and adolescents often become aware at an early stage of development that they have other abilities, other ways of thinking, and other interests than their peers. Such an impression is reinforced when parents, teachers, or psychologists tell them they are gifted. At present, we know very little about how such a labeling process affects development in children with different degrees of giftedness. Nonetheless, empirical research has shown that many gifted children and adolescents develop an intensive personal interest in the available psychological research on this topic.

(7) Finally, the interests of many critics of research on giftedness and its consequences for education should not be neglected. These are not only scientists who question the theoretical, methodological, and empirical foundations of such research but also educational scientists, sociologists, and policymakers who fear a one-sided intellectual promotion of a small group of individuals and an instrumentalization of such interventions for purely economic purposes.

Although there can be no doubt that many sectors of society have a strong interest in the phenomenon of giftedness and its study, this is based on a variety of needs and reasons. Such external conditions would seem to make it impossible to follow the ideal sequence of basic and applied research, of developing and testing suitable instruments and programs, and finally, a broad implementation of scientific knowledge. Ever since the beginning of the 20th century, the field of giftedness has been characterized by a variety of extremely heterogeneous scientific and practice-related approaches that run concurrently. It is impossible to discern one general system in either the history of research or in practice. The outcome is a remarkably large number of psychological, biological, educational, and social findings that vary greatly in their reliability and validity. This makes it extremely difficult for both scientists and workers in the field, for both experts and laypersons, to find their way through this complex and complicated field of theoretical approaches, methodological procedures, empirical findings, practical experiences, and contradictory evaluations.

It can be seen that the number of special journals, monographs, edited books, and essays on giftedness research as well as on practical interventions with gifted children both inside and outside schools is now almost incalculable. Hundreds of new publications are appearing every year. All this information needs to be organized and assessed including the different scientific models and theories, and the practical projects and programs. What is the role, for example, of general intelligence (usually expressed in terms of intelligence quotients) in the definition of giftedness? Do highly intelligent individuals, in general, also possess high creative potential? How do intellectual abilities relate to special mathematical, verbal, artistic, or technical talents? Do gifted and highly talented children develop in different ways or only more quickly than their 'normal' peers? In what ways do special learning programs influence development in the gifted? How do genetic and environmental factors impact on cognitive abilities and performance? What is the contribution of non-cognitive motivational and personal traits? How can we minimize the risk of classifying children wrongly as gifted or non-gifted? Do gifted students require special teaching institutions, or can they be promoted sufficiently within mainstream schools? Why are some gifted children only moderately successful in their adult careers, whereas some exceptional scientists, technicians, physicians, or artists were only average achievers at school? We can see that each question can generate further questions at increasing levels of complexity.

This second edition of the *International Handbook of Giftedness and Talent* is not just a representative overview on the current state of the art in the major research approaches and on the application of their findings to identifying and promoting the gifted, but also offers competent answers to the main questions in theory and practice. This statement applies equally to the first edition published in 1993. Not only did reviews in scientific journals praise the work as the first comprehensive presentation of the theoretical principles, empirical findings, and practical application of research on giftedness, but the book also rapidly became an international bestseller exerting a strong influence on work about and with gifted children.

The present second edition represents an admirable continuation of this tradition. Because of the dynamic advances and successes in research on giftedness and talent during recent years, the editors Kurt A. Heller, Franz J. Mönks, Robert J. Sternberg, and Rena F. Subotnik have taken care to ensure that the book has been revised completely, that 80% of the information is new compared with the first edition, that 22 more chapters have been added, that the international and interdisciplinary approach has been strengthened, and that particularly important fields of research on giftedness are covered by several different chapters that each take a different theoretical and/

---

or practical perspective. Indeed, the list of authors reads like an international Who's Who of the top researchers in the field.

In his foreword to the first edition, Howard Gardner speculated on what the pioneers of research on giftedness might have had to say about this book and what would have surprised them the most. Considering the same question seven years later after reading the more than 60 chapters in the *International Handbook of Giftedness and Talent*, I believe that they would have been fascinated by the breadth of new theoretical and procedural knowledge and amazed by not only the continuities (e.g. the decisive role of IQ in defining giftedness) but also the discontinuities in the basic research approaches over a long period of time. Although some might have been rather disappointed by the fact that important questions (regarding, e.g. the effect of genetic and environmental factors or the prediction of career performance in the gifted on the basis of developmental indicators during childhood) are still unanswered, in general, they would be impressed strongly by the state of the art in international research, by the intensive programs for the gifted in many countries, and by a handbook that reports this in such a comprehensive, representative, critical, constructive, and brilliant way. I am confident that readers of this second edition of the *International Handbook of Giftedness and Talent* will reach a similarly positive conclusion.

May, 2000  
Franz Emanuel Weinert

# Preface of the 2nd edition

The first edition of this handbook was published in 1993 and received critical acclaim for its achievement in bringing together international perspectives on research and development in giftedness and talent. In the years since 1993, the scholarly field of giftedness and talent studies has expanded and developed, welcoming contributions from researchers in related disciplines. Several theoretical frameworks outlined in the first edition have now been empirically tested and a number of new trends have emerged.

The second edition, containing over 80% new material, brings scholars up-to-date with the latest research in the field. The new material includes:

- Substantially revised chapters taking into account recent developments in the field.
- Twenty-two completely new chapters.
- Significant contributions from scholars working in related fields.
- An increased focus on empirically supported scholarship.

The second edition of the *International Handbook of Giftedness and Talent* represents the most comprehensive, authoritative and up-to-date reference work on giftedness and talent. Bringing together leading scholars and teachers from around the world, this volume provides an invaluable research tool to academics, researchers and students interested in giftedness and talent.

For the better part of the 20th Century, and especially during the past two decades, the nature, nurture, problems and achievements of persons described as gifted or talented have been theorized about and researched. Hundreds of studies are done each year dealing with every conceivable aspect of giftedness. These studies include quantitative and qualitative designs, experiments, surveys, case studies, evaluations and simple descriptions of programs and practices. They range in significance of the problems studied as well as their quality.

The first edition of the *International Handbook* offered readers a synthesis and critical review of significant theory and research conducted through 1993 on all aspects of giftedness in order to provide a sound knowledge base on which to guide educational policy and practice, and help frame the next generation of research questions. We aimed to provide researchers, practitioners and policy makers with a comprehensive, critical review of theoretical and empirical research and descriptions of program and practice dealing with all aspects of the nature, nurture and realisation of giftedness and talent.

Prepared by over 100 researchers and program developers from 24 different countries, the chapters of the second edition of the *International Handbook of Giftedness and Talent* provide authentic, state-of-the-art international perspectives on all aspects of identification and development of giftedness and talent. We believe the chapters represent the best scholarly, theoretical and empirical knowledge available on the topic, reflecting the contributors' judgements of the important issues, programs and practices. The *Handbook* also highlights needed research and promising avenues of program development.

A. Harry Passow, the third editor of the first edition, passed away in 1996. Two new editors have been invited to participate as co-editors: Robert J. Sternberg (Yale University) and Rena F. Subotnik (Hunter College) – both well-known in the scientific community and in the field of gifted education.

In order to distinguish the new (2nd) edition from the original, three fundamental changes have been incorporated:

- Perspectives from scholars in related fields.
- New scholarship emerging in the late 1990's on talent development in various domains.
- More focus on empirically supported scholarship.

The second edition of the *International Handbook of Giftedness and Talent* is divided into seven parts with a total of 59 chapters. They are divided into seven sections (parts) as follows:

- Part I: Changing conceptions of giftedness and talent.
- Part II: Development of giftedness and talent.
- Part III: Identification of giftedness and talent.
- Part IV: Gifted education and programming.
- Part V: Counseling and nurturing giftedness and talent.
- Part VI: Examples of country efforts, policies, programs and issues.
- Part VII: Present and future of research and education of the gifted and talented.

We have organized the *Handbook* to serve a broad audience of readers – students, teachers, researchers, decision-makers, administrators and others – who are concerned with nurturing talent potential. We think readers will find a meaningful balance of scholarship and practice which will provide a base for ideas and policies for the years ahead.

Finally, we would like to thank the contributors, most of whom have worked within a tight deadline. Without their efficient cooperation it would have been impossible to meet the publication goals of this second edition. Special thanks is owed to Franz E. Weinert for writing the Foreword of the second edition.

In addition, we would like to thank the editors of Pergamon Press/Elsevier Science—especially Gerhard Boomgaarden and Lesley Roberts and their colleagues in the production department—for their very professional handling of this publication.

# Conceptions of Giftedness from a Meta-Theoretical Perspective

Albert Ziegler<sup>1</sup> and Kurt A. Heller<sup>2</sup>

## Introduction

In this chapter conceptions of giftedness will be presented from a meta-theoretical perspective. The intention here is not to present individual conceptions, contrast their inherent advantages and disadvantages with one another or identify those points they have or do not have in common. Rather, the objectives here are to delineate meta-theoretical criteria which provide a sound basis for giftedness research and to examine the most important conditions which could influence the validity of conceptions of giftedness.

A brief survey of the present state of the theoretical development of conceptions of giftedness reveals the existence of three recurring points of criticism: (1) The empirical basis is often insufficient, (2) their ontological status is unclear, and (3) they often fall short of meta-theoretical standards set by the philosophy of science. In the following section, we want to explain these points of criticism in detail. The attempt to develop a constructive argument is the main purpose of this chapter. The goal is to formulate a conclusive response to them by the end of the chapter, which in and of itself enables a scientifically fertile coming to terms with the topic of giftedness research.

## Empirical, Ontological and Meta-Theoretical Difficulties with Conceptions of Giftedness

The fact that there is no object one can simply point to which demonstrates the existence of a gift or a talent appears to be trivial for a scientific branch like psychology which is largely based on constructs. However, is there at least indirect evidence that would support the postulation of gifts? The most important denial comes from the field of expertise research. Howe, Davidson and Sloboda (1998) seriously question how realistic the assumption of the existence of

gifts or talents is, or whether one is actually being taken in by a myth. Basically, there are at least three reasons for the empirical difficulties facing conceptions of giftedness. (1) Empirical evidence obtained with average gifted persons cannot easily be transferred to highly gifted persons. For example, several conceptions of giftedness incorporate genetic influences as a significant component of the basic meaning of talent. In fact, there is a large body of research that proves that genetic influences account for some inter-individual differences. Wagner (1999) indicates, and correctly so, that these genetic influences have only been proven by untrained persons. In the same vein, Ericsson (Ericsson & Crutcher, 1990; Ericsson, Krampe & Tesch-Römer, 1993; Ericsson & Pennington, 1993) arrives at the overwhelmingly convincing conclusion that the estimated performance barriers seen as genetically fixed upper boundaries can be overcome through suitable learning processes. (2) By and large, the second empirical difficulty can be attributed to the inadequate methods currently available for the identification of gifted persons. According to the predominant opinion, gifts are not automatically transformed into exceptional achievements which leads us to contend with the existence of quite talented underachievers (Butler-Por, 1993). On the other hand, it could very well be that we are speaking of persons who have attained eminent achievement; these could be either highly gifted or average gifted persons who have had successful learning careers. In sum, giftedness research can not make an absolutely clear distinction between a highly gifted person and a well-trained person or between an average gifted person and a highly gifted person not taking full advantage of his/her gift. (3) The last empirical problem is due to the rarity of talents. For example, a country like Germany would need to conduct several complete cohorts in order to find just one individual major chess master. The scope of the problem increases when one wants to ascertain specific components of giftedness such as genetic influence. For example, in order to assess these genetic influences among chess players one would need to implement twin and adoption studies within an already extremely

small population (cf. Thompson & Plomin in this handbook). Such samples are impossible to recruit.

From an ontological point of view, it is actually difficult to determine the precise ontological status of gifts. It seems to be clear that there is no direct correspondence between a gift and a natural entity, but rather that a construct is indicated. For example, Howe et al. (1998), in their devastating criticism of the talent construct, present a so-called list definition of talent, in other words talent as a composite of several necessary factors. Although some of the peer comments criticized of the individual points of the theory, none of them complained about the form of the definition as a list of criteria. A survey of the practical research reveals that talents seem to be handled as predictors indicated by variables such as intelligence or attributions of giftedness in a nomination procedure (see empirical publications in journals dedicated to questions involving talent and giftedness: *Creativity Research Journal*, *Exceptional Children*, *Gifted Child Quarterly*, *Gifted Child Today*, *Gifted Education International*, *High Ability Studies*, *Journal for the Education of the Gifted*, *Roepers Review*). On the other hand, it is difficult to accept talent as a proximal explanation for exceptional achievements. When an investigator attempts to explain why an exceptional achievement has occurred, he would need to analyze psychological processes, specific skills or physical structures (see Chi, Glaser & Farr, 1988; Ericsson & Smith, 1991; Hoffman, 1992). For example, when the basis or organization of the knowledge structures used by chess experts (Freyhof, Grub & Ziegler, 1992) or the capacity to mentally generate chess moves in advance (Holding, 1985) are investigated, an investigator would not be satisfied in using the expression 'giftedness' to explain such achievements. In certain ways, we are addressing the direct explanation of an exceptional achievement in terms of a methodological anti-gift-approach, since one would constantly attempt to break down gifts into psychological processes or entities.

From a meta-theoretical perspective, the consideration of current giftedness research as well as the existing theoretical basis of giftedness is striking in many respects. First, one must concede that it is difficult to justify the scientific necessity of gifts without becoming caught up in a vicious circle. Often, conceptions of gifts create their own legitimacy through empirical evidence of achievement eminence which are used to justify gifts themselves. Many arguments run along lines similar to this simplified example: If someone is a high achiever, it follows that he is gifted and vice versa; if someone is gifted, he will demonstrate exceptional achievements (as long as he is not restricted by unfavorable environmental conditions). Examples of this can particularly be found in the biographies of extraordinary persons (e.g., Ellis, 1927; Kretschmer, 1931). Therefore, conceptions of giftedness must also be capable of making a conceptional

differentiation between achievement eminence and gifts.

The second troublesome point concerning the construct of gifts from a meta-theoretical perspective is that there is a tendency to immunize them against potential falsification. This is of course not a problem if one is speaking of a theoretical term whose measurement more or less presupposes its existence (cf. Sneed, 1994; Sneed, Baber & Moulines, 1987), similarly to how a concept such as intelligence is handled. Intelligence, in the strictest sense of the word, cannot be falsified; at most it can be proven to be scientifically less fruitful. In the debate over the existence of talents and giftedness, the question as to who carries the burden of the proof of existence is posed often enough (cf. Howe, Davidson & Sloboda, 1998, as well as the open peer commentaries): Do talent researchers now need to come up with proof of the existence of gifts, or do their opponents need to offer proof of non-existence? In our opinion this question is poorly formulated and suffers under a *petitio principii*, i.e. the adoption of an unjustified tacit assumption. This exists within the universal assumption that gifts always—according to the proponents—or never—according to the opponents—are at the base of the behaviors leading to achievement eminence. In contrast, we believe that a conception of giftedness should allow for the possibility that a behavior leading to achievement eminence could, in fact, either be or not be based on the existence of a gift. A decision should be made in each case in collusion with an empirical clarification.

The third troublesome point from a meta-theoretical perspective is evidence of a significant decrease in progressiveness regarding the ability to move forward (Lakatos, 1978) seen in the last few years. Giftedness research is mainly a receptive research of psychology whereby methodological standards do suffer, in some respects, from deficits. In order to prove the first part of this claim one need only take a glimpse through the leading psychological journals. It becomes immediately obvious that practically all important scientific discoveries are not being obtained from subject pools with striking talents. Methodological deficits were evident in a meta-analysis of current empirical works appearing in peer-reviewed journals on giftedness by Ziegler and Raul (2000). Among other points, they confirmed that control groups were employed in less than one quarter of the studies! Some studies even neglected to indicate the number of subjects participating in their investigations.

The above depicted analyses of empirical, ontological and scientific aspects point to the necessity of a complete and thorough deliberation of the theoretical foundations of giftedness research. This does not necessarily entail the development and presentation of a new conception of giftedness, but rather a reflection on the basis upon which the forthcoming as well as current conceptions of giftedness can be evaluated.

In the next section of this chapter we will address the concept of giftedness, a term which has so far only been intuitively applied. In face of the abundance of various applications of the term currently in use, it is not possible to present an *all* encompassing concept of giftedness here nor to offer a complete overview of the various views of the construct. The only goal here is to provide an intuitive understanding for the following sections of this chapter; initially we will define the object, which giftedness research attempts to explain. Then a meta-conceptual model which we name the *critical state view of giftedness* will be presented, which should set the standards for the analysis and discussion of present conceptions of giftedness as well as for the development of future conceptions. Central components of such conceptions of giftedness will be addressed against this background, as will some virulent conceptual problems in the research field itself.

### Conceptions of Giftedness and Their Central Object

Exceptional achievements have always held the interest of mankind, whether they be found in folklore, sagas, everyday encounters, theology, philosophy, art, or recently in empirical science. Two matters are of central concern; first, those individuals enjoying social privileges were always tied to certain demands apropos achievement. For example, the kings and lords in ancient Greece were often attributed with physical strength in addition to their leadership qualities; this strength turned them into an effective protective factor with respect to external enemies. This theme is illustrated by the renowned battle for Troy whereby every son of the Trojan King Priamos as well as every Greek leader was ascribed the status of a hero and, therefore, their actions mainly determined—besides the actions of the gods—the outcome of the battle. Second, in addition to this social legitimization function, there was always a vital interest in seeking out the source of exceptional achievement. Naturally, the explanations have varied to a great degree over the course of history. In hindsight, these constructs seem to have experienced a period of development which corresponds particularly well to the *Three Phase Model* proposed by the French founder of Positivism, Auguste Comte (1798–1857). In the first phase, the theological state, man interprets the worldly phenomenon in terms of supernatural beings, usually as gifts from the gods. In the second phase, the metaphysical or abstract state, the causes of all worldly phenomena can exist outside the physical world and are therefore secure from empirical encroachment. In the third and final phase, the scientific or positive state, a controlled empirical approach is incorporated into investigation.

In fact, initial encounters with exceptional achievements in the ancient world were explained through

constructs borrowed from religion. In Greek mythology, divine descent (Sisyphus, Achilles) or divine mercy (Odysseus, Tiresias) were often believed to be the sources of heroism, intelligence or prophetic abilities. Plato in Greece and Confucius in China have already addressed the topic of ‘heavenly’ children. The Bible is explicit on the theme in Romans 12:6: “We have different gifts according to the grace that is given to us.” The phase described as metaphysical is characterized by a gradual change in the understanding of gifts or talents which can now be more closely tied to individuality. Studies in speech etymology show that these facets in meaning had already started to differentiate by the 4th century, a change which first surfaced in middle and north European language groups in the 14th century. Talents were then understood more in terms of individual aptitudes (Kluge, 1967). The philosopher Paracelsus in 1537 already used the term ‘talent’ in the sense of a mental aptitude (Passow, Mönks & Heller, 1993). On the other hand, explanations of achievement eminence, although no longer referring to religious sources, were still not being investigated by means of empirical methods. During the middle ages, the belief was spread that exceptional achievements were the result of extra-sensory causes (Fels, 1999). The gifted were expected to die earlier as a sort of compensational justification (Stanley & Benbow, 1986). A further example is that of the genius cult in the age of Enlightenment and Romance, whereby genius was something spiritual, here represented by an entity in a state absolutely removed from that of normal comprehension. “Genius is another psycho-biological species, differing from man, in his mental and temperamental processes, as man differs from the ape” (Hirsch, 1931, p. 298). Along similar lines, Hollingworth recounts the opinion that: “The contemplation of genius thus came to be accompanied by a kind of superstitious awe, and the notion gained currency that people of genius constitute a separate species” (1929, p. 3). Metaphysically oriented explanations for giftedness have been common constructs in scientific theories, even in the 20th century, and can still be found in commonplace theories subscribed to today. A prominent example would be that of the ‘blue blood’ ascribed to the aristocracy in medieval class society which served to legitimize their social superiority and spiritual claim to leadership. Only with the dawn of psychology and the consequent development of methodological standards could the explanation of achievement eminence gradually enter the third phase, or the positive state. Here, unusually successful learning processes as well as talents or gifts were seen as the causes for exceptional achievements. Talents or gifts themselves became more assessable under scientific measurement than intelligence; they were seen as the interplay among several psychological components, a result of specific genetic dispositions or as the result of learning processes. From a historical angle, one can

most probably say that Galton (1883) and, somewhat later, Binet (Binet & Simon, 1916) can be credited with leading giftedness research into the positive state. Their fundamental beliefs, that talent can be measured and that it differs from person to person in gradients rather than quality led to a revolution in the understanding of gifts.

Nowadays, a look through the relevant literature pertaining to giftedness research can be quite confusing due to the amazing variety of definitions for giftedness or gifted persons. A frequent definition, upon which many investigative studies are based, equates giftedness with high levels of intelligence. Often, an arbitrary point will be set beyond which one is considered to be gifted. Other definitions of giftedness have expanded on this limited definition and gone on to include exceptional achievement in various domains. For example, DeHaan and Havighurst (1957) named intellectual abilities, creative thinking, scientific abilities, social leadership qualities, mechanical abilities and artistic abilities in their definition. Another frequently quoted definition of gifted (children) was offered by Marland (1972, p. ix): "Gifted and talented children are those identified by professionally qualified persons who, by virtue of outstanding abilities, are capable of high performance." Similarly, Heller (1989) formulates giftedness as "the individual cognitive and motivational potential for—as well as social and cultural conditions of—achieving excellent performance in one or more areas such as mathematics, languages, or artistic areas with regard to difficult theoretical vs. practical tasks" (p. 141). Conspicuous in this definition is that it is based on achievement *potentials* which do not necessarily have to be realized; however, definitions based on *performance* can also be found. For instance, Götze (1916) wrote that talent can only be measured by achievement. Similarly, Tannenbaum (1986) sees talent as a product of a labeling process and the corresponding gifted persons as "outstanding contributors to the arts, sciences, letters and general well-being of fellow humans" (p. 33). Furthermore, he reserves *true* giftedness for adults, a talent which is distinguished by particular achievements, while children can only be accorded a *potential* giftedness. However, the general opinion is that the gifted do not necessarily need to demonstrate achievement eminence, but rather that they can attain this state more easily than other persons. Those who do not achieve to the levels predicted by their potential are said to be underachievers (cf. Butler-Por, 1993; see also Thompson & Plomin in this handbook).

### *Conceptions of Giftedness*

Regardless of whether one is considering a psychometric conception of high ability in terms of the disposition for extraordinary achievements (in specific areas) or a cognitive conception regarding domain-

specific competence vs. performance in the sense of achievement eminence, one finds that all new theories tend to favor *multi-dimensional* models of high ability (for example Gagné, 1985, 1993; Gardner, 1985; Heller & Hany, 1986; as well as Sternberg, 1985, 1988, 1990; Heller, 1989, 1990, 1991). Theoretically based diagnostic and promotional concepts need multi-dimensional formulations which cannot be adequately realized through (one-dimensional) IQ definitions which are limited by cut-off levels inherent in a model based on threshold values.

In early childhood, ability initially manifests itself as a relatively unspecific individual behavioral potential. Here, the *interaction* with the social learning environment is significant for highly gifted children in that a reciprocal influence between the child's behaviors and the parental breeding practices is characteristic. According to Scarr and McCartney (1983), inherited ability potentials—including inter-individual intelligence differences—become relevant for individual selection and engagement of information stimuli offered by or made available through the social environment (see Monks & Mason and Thompson & Plomin in this handbook). Modern intelligence and talent theories favor domain-specific conceptions, exemplified by the multiple intelligence model developed by Gardner or the Munich Dynamic Giftedness Model, both of which will be briefly described in the following text.

Gardner differentiates seven intelligences:

(1) *Linguistic* intelligence. This includes the sensitivity to the definitions of words as well as effective language based memory skills.

(2) *Logical-mathematical* intelligence. Here general logical and special mathematical thinking abilities are referred to.

(3) *Spatial* intelligence. This form of intelligence refers to the conception and perception of space as well as abilities involving spatial memory and thought processes.

(4) *Bodily-kinesthetic* intelligence. Psycho-motor abilities of this type are needed, for example in achievements in the fields of athletics or dance.

(5) *Musical* intelligence. This includes not only musical competencies in the narrowest of senses, but also includes mood and emotion. For a more detailed discussion see Perleth & Mönks, in this handbook.

(6) *Intrapersonal* intelligence. This refers to a sensibility regarding ones own sensory world.

(7) *Interpersonal* intelligence. This concept of social intelligence refers primarily to the ability to differentially perceive the needs of others.

Recently Gardner has added one further type of intelligence to these seven, and has suggested two further types as candidates for inclusion, namely:

(8) *Naturalistic* intelligence. Here the author is referring to the ability to discern patterns in the living world.

(8<sup>1</sup>) *Existential* intelligence (in myth, art, science, philosophy) and *Spiritual* intelligence (whatever that may mean). Gardner labels the last two intelligences as intelligence candidates due to the lack (so far) of empirical validation.

Along the same line, the content of the Munich Model of Giftedness and Talent (see Fig. 1) makes distinctions among relatively independent forms of ability which themselves are relevant for specific achievement areas. Besides *intelligence* (linguistic, mathematical, technical-constructive and other dimensions), the following talent dimensions have been investigated:

- (1) *Creativity* (originality, productivity, elaboration, flexibility, liquidity, etc.).
- (2) *Social competence* (planning ability, leadership and the control of social interactions among others).
- (3) *Musical-artistic* abilities (i.e. musicality).
- (4) *Psychomotoric* (hand and body motor skills).
- (5) *Practical intelligence* (i.e. the command over daily and or vocational challenges or problems).

These talent dimensions represent—as in Gardner’s Theory—the fundamental, but by no means all possible forms of ability. In a variation of the model suggested by Ziegler and Perleth (1997), an attempt to

make a connection between talent research and expertise research is made (see Fig. 2). Their model spans from the taking up of an activity to the achievement of expert status. In the model, antecedent and marginal conditions of exceptional performances are taken into consideration just as much as the use of talents in an active learning process.

*Person’s internal performance dispositions* which set maximum performance levels are postulated as an antecedent condition of exceptional performances. Here, following Ackerman’s theory (1987, 1992), cognitive, perceptual and motor talent factors are differentiated, whereby the importance of domain-specific foreknowledge is additionally included. However, only very roughly estimated talent factors are named, which, of course, would have to be subdivided more finely for single career fields. For example, cognitive abilities can be further subdivided into creative, analytical or logical abilities.

Talent factors require favorable marginal conditions for their use; without *active learning* which is supported through *favorable personality characteristics* and suitable *environmental features*, talents vanish unused. The resulting performance at a given point in time is, according to this, seen as a product of the

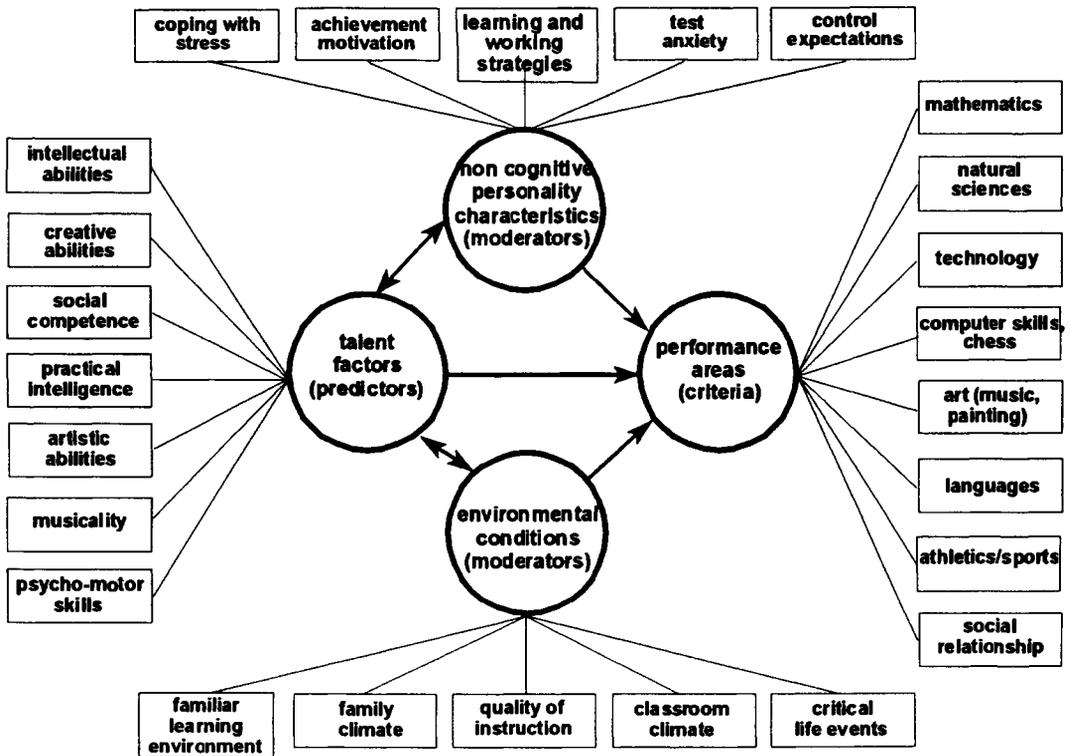

Figure 1. The Munich Model of Giftedness and Talent as an example of multidimensional concepts (according to Heller, 1990, 1991; Heller & Hany, 1986; Perleth & Heller, 1994).

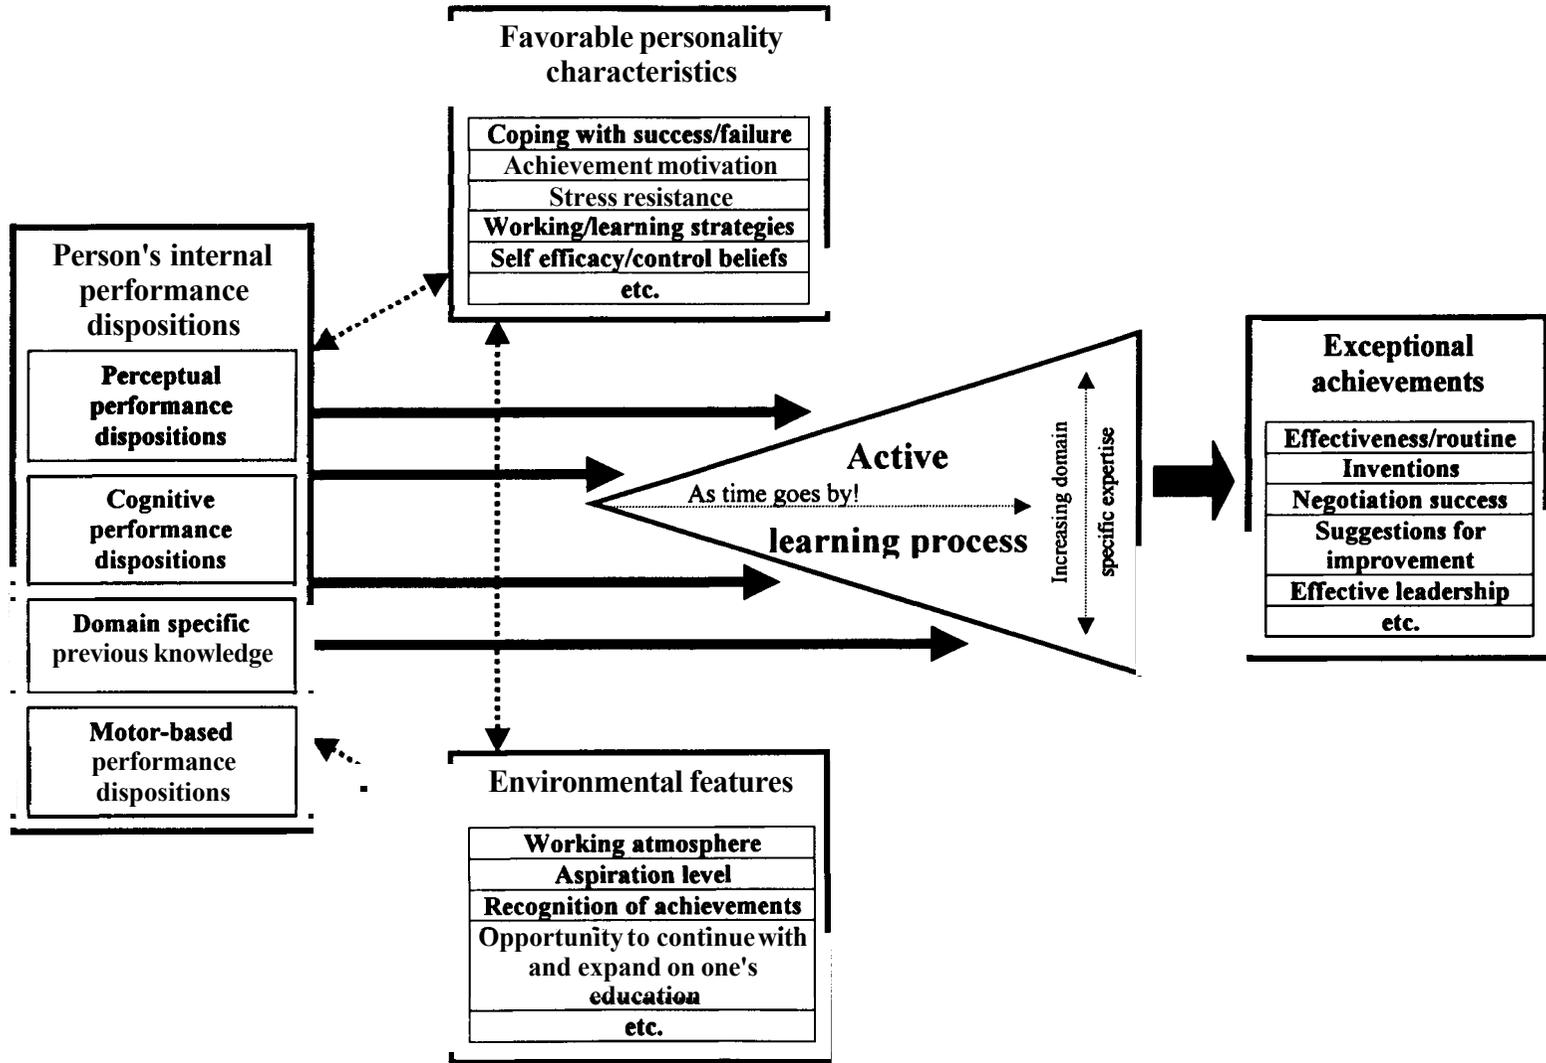

Figure 2. The variant of the Munich Dynamic Model of Giftedness by Ziegler

interplay of the talent, motivational and environmental factors that are analytically differentiated in the model.

It should be clear that multiple interaction and compensation processes take place between these factors. The development of expertise is dependent upon the use of the opportunities for experience and learning offered in the environment, which, however, must not be seen as static factors. In contrast to that, the talented must deliberately look for them according to their growing abilities and match them to their increased performance level. Thus, a performance-oriented company climate can probably level out an unfavorable individual performance motivation; in the same vein non-optimal intellectual performance preconditions can be compensated for by further educational offers within the company. Therefore, not only a high domain-specificity concerning the task areas focused upon is to be expected, but also a highly individual expertise process.

A *psycho-social* conception of high ability was suggested by Tannenbaum (1983, 1991). Here the independence of every form of talent from social demands and validation contexts is emphasized. Furthermore, Tannenbaum points to the role *chance factors* can play in the transformation of individual talent potential into achievement behavior. Heller and Hany (1986) discuss *critical* life events, while Feldhusen (1986) sees *self-concept* as a central personality variable among the highly gifted. Such differentiated ability concepts are not only relevant for the identification of highly gifted adolescents, but also for the sponsorship of extremely talented members of specific domains.

Finally, a brief look should be taken at Renzulli's influential *Three Ring Model* (Renzulli 1978, 1986) of high ability, which has in the meantime been expanded upon by Mönks (1990) from the developmental psychological perspective of the social settings family, school and peer group. Despite some—justifiable—criticism of such implicit models, they often show a large affinity for the practical problems faced by educational psychologists (Sternberg, 1993), which may explain the attractiveness of the Renzulli Model: In this model giftedness is conceptualized as the lucky coincidence of above average (general) intelligence, creativity and task commitment; see also Renzulli & Reis in this handbook. In general, dynamic models as they are conceptualized in investigations based on cognitive approaches seem to be more effective for practical needs than psychometric models of ability which are preferred in the genetically oriented and neuroscientific basis research as well as in the developmental and differential branches of psychological and psychodiagnostic research and practice. Both research paradigms are indispensable, whereby at a glance the profit they bring in pedagogical applications pushes their supplementary functions into the fore-

ground.

While the giftedness theories discussed thus far have been, more or less, psychometrically founded and, thereby, oriented on abilities and traits, recent research based on cognitive psychology has been gaining new significance. Included here are information theory models such as the cognitive component theory developed by Sternberg and his research group (Sternberg & Davidson, 1986).

In a further development of earlier research theories on analog thinking (Sternberg, 1977), Sternberg (1985) presents his *Triarchic Theory of Intelligence*. This consists of three subtheories designated as the context, two-facet and component theories.

The *context subtheory* refers to how intelligence is culture specific. Here, intelligence needs to be defined within a socio-cultural context, or in other words as the individual's goal-directed adaptation of a relevant living environment as well as its organization and selective integration. Aspects of social and practical intelligence are also addressed.

The *two-facet subtheory* attempts to bridge the (apparent) contradiction found between assumptions regarding information processing offered by thought psychologists and learning psychologists. Thought is only required for problem solution when the individual is confronted by an inadequate knowledge or experience base, in other words when one is dealing with a novel problem. According to Sternberg, human intelligence can be particularly well measured in situations where the application of existing information is necessary for, but not sufficient to, arrive at a solution for this new problem. In addition, available information bytes must be selectively encoded in that a decision must be made as to whether the information is relevant or irrelevant with respect to the solution of the problem. They must be suitably combined, and then these results must be reviewed and scrutinized. This process is, however, just one facet, the second facet refers to subroutines in the problem solving process or the automatization of information processing. The more extensive the repertoire of available automated (partial) processes, the less the burden on the actual thought which must be applied in the solution of the problem. A first grade student, who has not yet automated the operations associated with reading and writing readily available to older students and adults, would need much more time to manage writing tasks than, say, a seventh grade student. Similarly, a novice auto driver would progress at a much more cautious pace than a routine driver, so long as an insufficient number of automatized driving elements are available.

Finally, in the *component subtheory*, Sternberg differentiates among (a) performance components, (b) meta-components and (c) knowledge acquisition components. *Performance* components refer to basis operations such as selection and routine organization. In addition, control processes are needed which are

here called *meta*-components due to their presumed universal validity. Included here are operations such as problem recognition, selection of appropriate performance components and form of representation (verbal, numeric, figural, illustrative), strategy regarding the combination and re-ordering of performance components, as well as control over execution and solution. *Knowledge acquisition* components steer the learning process.

The *Triarchic Theory of Intelligence* considers: (1) internal (person related) process elements, i.e. meta-components of the control and evaluation of behavior; (2) performance components, which are responsible for the actual solution of the problem (through thinking and learning transfer which regulates behavior) and; (3) knowledge acquisition components, which refer to both declarative and procedural knowledge (i.e. factual knowledge vs. know-how). The object of Sternberg's (1985, 1986, 1988, 1991, 1997) analyses in the area of cognitive psychology is inductive thinking, whereby three insight skills, selective information processing, combination processes and comparative processes were experimentally investigated. According to a series of empirical studies, the highly gifted can particularly be differentiated from normally gifted persons in how these process components are engaged in the processing of information in open or complex and difficult logic problems.

Psychometric and cognitive approaches to giftedness research are often considered to be opposing and incompatible approaches. We are of another opinion. In the early stages of intelligence measurement, the psychometric approach and the experimental approach appeared to be completely irreconcilable, as observed in the memory experiments conducted by Ebbinghaus and Binet. It is only in recent years that signs of a cohesion have again become apparent; this change is only meaningful to the diagnostics of giftedness regarding the degree to which the psychometric and cognitive approaches can complement each other. While the psychometric paradigm for behavioral prognoses still forms an indispensable foundation (without bringing in 'psychological explanations'), important conclusions regarding the causes for and conditions surrounding human information processing and intellectual problem solving are expected from process analyses in the cognitive paradigm. In this manner, inter-individual cognitive ability differences are to be confirmed through a series of cognitive process analyses, i.e. those regarding language comprehension, logical thought patterns or spatial perception and understanding. Studies in the expert-novice paradigms appear to be particularly successful here. In such studies the cognitive processes which significantly differentiate beginners from advanced achievers in a certain area (language competence, mathematics, technology, chess, etc.) are specified.

Sternberg and his co-workers ascertained the following six components based on their component analyses of thought processes (Reasoning factor I=Induction), whereby highly gifted and normally gifted students were found to differentiate in the solution of difficult, complex problems: (1) decisions as to which problem needs to be solved, i.e. what the actual problem at hand is; (2) planning appropriate steps leading to a solution; (3) the choice of a suitable step; (4) choice of a level of representation (oral, symbolic, illustrative); (5) allocation of attention; (6) control over the range of problem solving activities. Evidently, the necessary planning and direction competencies in the sense of meta-components of cognitive control are responsible for each and every partial step (inference, mapping, application, comparison, justification, response).

Despite the striking diversity of concepts of giftedness, it is interesting to note that all conceptions agree that exceptional achievements can be explained by giftedness. Furthermore, concrete research on giftedness is concerned with a section of human behavior, one which can be measured against a standard of excellence—in the sense of being either better or worse (McClelland, Atkinson, Clark & Lovell, 1953). Usually, one can speak here of three types of standards of excellence: (1) achievements, which are assessed by applying a critical norm under the guidance of objective criteria; (2) inter-individual norms, which are used to contrast individuals on one assessment dimension; and (3) intra-individual norms, which offer the opportunity to compare the present achievements of a person with his earlier achievements. All of these measurement techniques have been used in giftedness research, whereby the first two have clearly been the dominant choices. For instance, unique artistic, scientific or athletic feats would be acceptable demonstrations of objective indicators of exceptional talents of the same caliber as age relevant exceptional academic achievement. Certainly, through intra-individual measurement, one could demonstrate a rapid growth in learning and accept this as a sign of exceptional talent (e.g. Feldman, 1980; Feldman & Goldsmith, 1986; Radford, 1990). To sum up, recent conceptions of giftedness are not united as to whether gifts are only potentials for eminent achievement or can only be indicated by eminent achievement. However, they all agree that gifts explain eminent behavior, which itself can be measured against a standard of excellence. Unfortunately, by accepting a standard of excellence in the field of giftedness research, four problems unique to this subject emerge which will be discussed in the following sections: (1) the application problem, (2) the focus problem, (3) the reference problem and (4) the significance problem. These four problems stand in a hierarchical relationship to one another whereby a decision must be finalized for one problem before the next one can be considered (see Fig. 3).

**Application Problem**

The application problem addresses the problem of how to determine which domains deal with differences in achievement levels, thereby permitting the application of a standard of excellence. Various researchers have indicated that these areas are also to be seen as valuable in another sense; when one thinks of achievement, one is more prone to think of academic and scientific areas, or artistic domains such as music, painting or literature. Idiosyncratic works of art, on the other hand, are not usually considered to be valid expressions of extraordinary talents (Tannenbaum, 1986). This does, however, reflect an unwarranted preference among researchers to react to changes in taste by seeing the blossoming of extraordinary talents tomorrow in an area which only yesterday was hardly worth mentioning. The concept of a standard of excellence thereby contains a feature of a relativistic nature which can be seen as a type of silent agreement. For example, Tannenbaum (1986) distinguishes among four types of talent: *Scarcity talents* lead to improvements considered to be socially valuable, *surplus talents* elevate people's sensitivities with splendid achievements in art or philosophy. *Quota talents* fulfill roles which are limited by the needs of the society. Tannenbaum's last category, *anomalous*

*talents*, is interesting in that it concerns abilities which are of no use to society whatsoever, such as those depicted in the *The Guinness Book of World Records*. Included here are also anachronistic talents which may have been suitable to one of the other talent forms in a different era, but are worthless today. This type of list-forming makes it absolutely clear that the underlying classification is in no way founded on psychological considerations, but rather on extra-psychological criteria which are not further expounded upon by Tannenbaum, and which are probably based on some other social value, rarity or achievement component. The classification of talent in Sternberg's *pentagonal implicit theory of giftedness* is also dependent on the distribution of talent levels and social values (Sternberg, 1993). His five necessary and jointly sufficient criteria of excellence, rarity, productivity, demonstrability and value also circumvent psychological considerations by finding their roots in commonplace theories.

In fact, the starting point for most scientific constructs is rooted in common, everyday concepts (cf. Stegmüller, 1970); for example, color theory originated with sensual expressions which were accessible to all. However, the ultimate goal of a scientific branch is to be able to transform common, everyday concepts into scientific expressions such as the description of colors through the frequencies of light waves. In exercising self-criticism, the field of giftedness research must admit that it has not yet been able to attain the level of scientific advancement which allows for a common definition of its research object in favor of a psychologically based construct. We will, for the time being, set this point aside and address it once again later in the text.

**Focus Problem**

Binding standards of excellence are not readily available in all areas in which achievement is being investigated; this poses not only a serious problem for convergent achievements, but an even greater one for divergent achievements. Even when a consensus can be reached regarding whether a standard of excellence can be applied in a specific domain, one cannot be certain of which aspect to focus on. For example, one would assume that in order to evaluate a high jump, one would consider the height the jumper can attain. It goes without saying that specific types of jumps are ruled out by the regulations governing the sport (for example, today, the frequently employed flop technique in which an athlete jumps over the crossbar backwards is only permitted after a lengthy discussion). In the earlier phases of this sport discipline, the jump technique was assessed along with the height of the jump itself, similar to the manner in which ski jumps and figure skating are still assessed today. In subsequent domains, such as those in the academic field, complicated assessment techniques must be

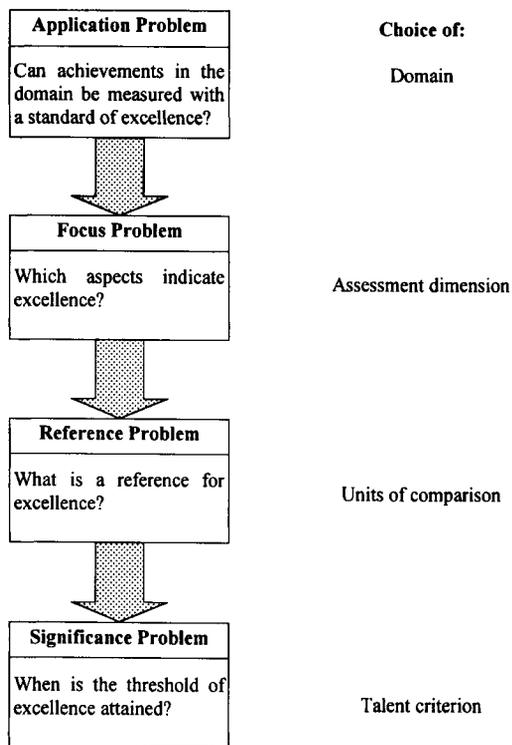

Figure 3. Hierarchical relationship among the four problems arising from the application of a standard of excellence.

devised or complex psychometric scales like IQ tests must be developed. It should be mentioned here that even by establishing which aspects of a domain are to be subjected to a standard of excellence, this cannot be based solely on objective criteria. Whether academic achievement is assessed with paper-and-pencil-tests, oral examinations or by the success in real life situations, is not an inevitable consequence of the choice of domain.

### *Reference Problem*

Even when the dimension on which the achievement eminence in a domain can be determined is clear, it is still necessary to establish a norm against which achievement can be measured. Reference norms have already been introduced in this text: there are criteria-based, inter-individual and intra-individual norms. In using criteria-based norms, one highlights exceptional achievements that result from facets of a unique character or those which only very few people can reproduce. One can include discoveries and works of art among these types of achievement; these examples are founded on the assessment of products which are a result of actions undertaken. These actions can also be assessed on a criterial basis, for instance, the incredible feats performed by memory or arithmetic geniuses who can commit columns of numbers to memory or seem to have magical capacities for mental calculations at their disposal. Such achievements fall, in many cases, so far outside the range of normal abilities that the application of an inter-individual standard of excellence for these phenomena would only be a waste of time. Inter-individual achievement comparisons often make allowance for an age norm as well as for the rarity of the phenomenon (Sternberg, 1993). Thereby, an accomplishment which is sub-normal for adults would be unexpected for a younger person at an earlier developmental stage (e.g. child prodigies, early readers). In imposing an intra-individual norm, one would more than likely be looking for quick learning growth rates. The average age of subjects being evaluated using this type of reference norm should be relatively low, typically childhood or early adolescence is the ideal level. However, we want to stress the fact that there are no objective criteria available which allow us to prefer one type of reference norm over another.

### *Significance Problem*

In the last stage, a classification or assessment, we are faced with the question of what qualifies as an achievement to be counted among the objects to be explained through giftedness research. Is it merely the top 10% or those who perform better than two standard deviations above the average who comprise the potential candidates for studies of giftedness? What sorts of learning growth would indicate talent? As long as no criteria regarding the actual understanding of gifted-

ness are at our disposal, one must be content to turn to ad hoc criteria such as percentages or international acknowledgments for the foreseeable future. The search for an end to the paralyzing and crippling discussion of percentages and optimal identification procedures will keep the community of giftedness researchers busy for quite some time as long as proven psychological criteria are not available to bring this discussion to a decisive end (cf. Rescher, 1995).

### **The Critical State View of Giftedness**

In the following, we present the meta-conceptual framework for the *critical state view of giftedness*, a model which offers a meta-theoretical basis for an assessment regarding the content of present conceptions of giftedness. In the first step, four postulates will be introduced and substantiated which any conception of giftedness must be able to fulfill.

#### *Postulate 1: Temporal Precedence*

We will start with the assumption that gifts form a causal relationship with exceptional achievements; consequently, they must meet all of the theoretical and scientific criteria which are usually demanded in cases of causality (Achinstein, 1983; Bromberger, 1992). Of particular significance in this context is the criteria of temporal precedence, originally introduced by John Stuart Mill (1806–1873). Applied to the field of giftedness research, this criterion demands that a gift precedes the eminent behavior it is supposed to explain. The acceptance of this cause-and-effect postulate has decisive consequences for the formation of a conception of giftedness in that it precludes the possibility for a performance oriented definition. This becomes clear when one considers the prospects of seeing gifts as explanations for current actions; the negative consequences of this attempt are best demonstrated with an example of an explanation for an exceptional achievement. If one would want to explain an ingenious move made by the current strongest chess player in the world, Gary Kasparow, one would have to call attention to his outstanding specific knowledge of the game, his ability to conduct mental calculations or his evaluative abilities (Holding, 1985). It would now be awkward instead to want to explain this ingenious move through one particular gift or talent.

Important here is that the actions being undertaken can always be resolved through fundamental psychological constructs, without having to rely on explanations through gifts. This is also the fundamental reason for claiming that gifts precede the actions which lead to achievement; otherwise they would merely be unsophisticated, pointless constructs inferior to actual-psychological explanations. Therefore, Postulate 1 maintains that one must assume that the gifts which intend to explain exceptional achievement are temporally precedent.

*Postulate 2: Fulfillment of the 'inus' Condition*

Mackie (1975) suggested that causes need to fulfill an 'inus' condition when they intend to be granted some degree of explanatory value; his basic idea can also be applied to gifts. An *inus condition* for some effect is an *insufficient but non-redundant part of an unnecessary but sufficient condition*. Before trying to apply this complicated formulation to the field of giftedness, an example would best serve to clarify it. Assume that a burning cigarette has started a forest fire. The burning cigarette, by itself, is not sufficient (there are many forest fires not caused by burning cigarettes), but non-redundant (because in the circumstances hypothesized there was no other condition present which would have ignited the flammable materials). The burning cigarette is, however, a part of some constellation of conditions that are jointly sufficient for the forest fire. Moreover, given that this set of conditions occurred, rather than some other set sufficient for the forest fire, the burning cigarette was necessary: Without it, the fire would not have occurred. Usually, the causes of an event are complex, and we often single out one of those conditions because there is something unusual about that condition. The presence of oxygen may be just as necessary for the fire as the burning cigarette; but because that is a condition that we can usually take for granted, we would not mention it.

Gifts should, admittedly, be able to explain exceptional achievements, however, they are certainly not sufficient to do this in and of themselves. For instance, in addition to gifts one must take learning opportunities, a high level of motivation, and a supportive environment into consideration (e.g. Gagné, 1993). Let us further assume that this entire set of additional factors are realized, then the gift would be non-redundant within this set in that without this gift the exceptional achievement could not be accomplished. When one considers the entire constellation surrounding giftedness, gift inducing personality traits and a supportive environment, one concludes that they are sufficient for the prognosis of exceptional achievement, although not necessary. Similar exceptional achievements in this field could be based on completely different constellations of antecedent conditions. In the case of the forest fire described above, oxygen fulfills the *inus condition* just as well as the burning cigarette. We are, however, inclined to name the burning cigarette as the cause of the forest fire. In the same vein, the fulfillment of the *inus condition* is not sufficient to identify a gift, it only serves to single out potential candidates. The next two postulates offer assistance in recognizing which candidates are indeed actual gifts.

*Postulate 3: Giftedness as a Personal Characteristic*

Postulate 3 is more than likely to be acceptable to most giftedness researchers; gifts denote specific personal

variables, and not environmental variables. Consequently, this excludes various further potential causes for achievement eminence which, although meeting the *inus condition*, do not meet that of Postulate 3. Let us assume that early behaviorists were correct in asserting that the environment is the ultimate cause of behavior. Thus, in a hypothetical case, which may be fully correct in the particular case of a specific achievement, the environmental circumstances alone would be sufficient in meeting the *inus condition*. Therefore, a particular gift would not have to exist in order to enable exceptional achievement.

Therefore, Postulate 3 disallows environmental factors as potential gifts, although it does not exclude the possibility that personal factors, which one would be reluctant to classify as gifts, could be distinguished as potential gifts. An extreme example of this, which adequately illuminates the problem here would be as follows: Each and every vital event in one's life (e.g. heartbeat), which could occur simultaneously with a gift is fully capable of fulfilling the first three postulates of temporal precedence, the *inus condition* and of being a personal variable. Nevertheless, one would be reluctant to accept a heartbeat or a functional digestive system as a cause for eminent achievement.

*Postulate 4: Theoretical Significance*

The postulate of theoretical significance gives expression to an established meta-theoretical criterion according to which a theoretically meaningful causal mechanism between antecedent (here: the gift) and explanandum (here: achievement eminence) must exist. In causal explanations, two or more states of affairs are theoretically tied to one another in such a way that one state of affairs brings about or produces the other state of affairs (Bunge, 1967; Stegmüller, 1970). In order for a gift to be a valid cause for achievement eminence, the achievement must be preceded by the gift (see Postulate 1). Furthermore, an invariant conjunction of the gift and the behavior leading to achievement eminence must be in evidence and an underlying mechanism or psychological structure must theoretically guarantee the necessity of the conjunction. One would not realistically expect to demand deterministic relations here, rather, one can give a new probabilistic interpretation to Postulate 4. However, the problem of when theoretical significance is manifest is now, as ever, unclear from a meta-theoretical viewpoint, and one can always resort to rules of thumb. In any case, it should be clear that gifts should have some effect on the behaviors leading to achievement eminence through processes which can be described by means of *psychological theory*. These theories could be based on a structure or configuration of attitudes, intelligence theories, cognitive theories etc. that facilitate or bring about the exceptional performance. On the other hand, no psychological theories take up the position that processes as vital for

life as the heartbeat itself are of psychological significance for achievement eminence.

Often it is the empirical nature of a theoretically maintained mechanism which is difficult to command, particularly when the random samples are troublesome to recruit or the condition constellation of achievement eminence demonstrates unique characteristics. In this case, the empirical investigation of the theoretical significance should, at the very least, be substituted by verification that no third variable controls both, or mediates between, the gift and the behaviors leading to eminent achievement. This sort of makeshift operation does not ensure the identification of gifts, but it does preclude the identification of absurd internal factors as being gifts. It may be that these aforementioned vital processes preclude the behaviors leading to achievement eminence, that they fulfill the inus condition and are certainly personal variables, but they can in no way be established as mediators which arbitrate between an initial state and the behaviors leading to achievement eminence.

Another problem is presented by internal factors which promote the development of achievement eminence, but are traditionally not considered to be gifts; two examples can be differentiated according to the degree of their complexity. *Factors of a low level of complexity* find themselves in a *complementary relationship* with gift factors, in other words, talents and these other factors (i.e. variables which support gifts or favorable environmental conditions) are necessary for the development of achievement eminence. *Factors of a high level of complexity* are, in contrast, *inclusive* and encompass, in addition to further gift promoting factors, the gift itself.

An example of factors with low levels of complexity is offered by Gagné (1993; see also Sternberg in this handbook). He differentiated (to a large extent innate) gift variables (intellectual, creative, socio-affective, and sensori-motor aptitudes) from so-called (intra-personal and environmental) catalysts which are decisive for the translation of gifts into talent. Environmental catalysts have already been ruled out as gifts through Postulate 3. Problems are admittedly brought up by intra-personal catalysts such as motivation or personality. They do meet the requirements of Postulates 1, 2 and 3, but are incapable of demonstrating theoretical significance since no psychological mechanism can be cited which allows these catalysts to be converted into the very behavior which is considered to be eminent. For instance, if one were to decompose chess expertise as Holding (1985) did in his *SEEK Model* into the subskills Search, Evaluate and Knowledge, one is left with motivational constructs on entities which are unknown to the theory, and which do not allow themselves to be converted into these three subskills within the language of the *SEEK Model*. On the other hand, the ability to perform complicated mental calculations could be a gift, since this ability

underlies one of the subskills (Search) of the *SEEK Model*.

An example of a factor of a high level of complexity is offered by Ericsson's theory of *deliberate practice* (e.g., Ericsson et al., 1993). In comparison with mere experience, deliberate practice (goal oriented and conscious training, which is maintained over a long time period) denotes an advanced form of experience. It is a behavioral style which encompasses personality factors such as motivation and cognitive skills as well. However, the decisive question here is whether highly inclusive constructs such as deliberate practice can be identified as gifts (for the sake of the discussion let us assume that their influence could also be empirically confirmed). Three facts speak against this. In the first place, they are of such a complex nature that they can encompass environmental factors and intra-individual catalysts as well as gifts themselves. Such a wide concept of giftedness seems also to have too much of an inflationary effect on the construct of giftedness. Second, this partially contradicts Postulate 3, according to which gifts can only be personal variables. One could take a more narrow definition of deliberate practice, exclude environmental factors and define all other internal factors as gifts; this, however, leads us to our third argument which was already addressed in the discussion of Gagné's intra-personal catalysts. For these type of intra-personal catalysts—such as Ericsson's suggestion of a high tolerance level for frustration which enables lengthy, strenuous learning processes—there exist no psychological mechanisms which lead to questionable behaviors which enable achievement eminence. Once again, we are confronted with various theoretical languages which refer to different psychological constructs.

#### *Features of the Critical State*

Behavior patterns which lead to achievement eminence are rooted in the interaction of several factors in which scientists are convinced that giftedness plays a crucial role. In the previous section criteria were named which must be fulfilled in order for a variable to be identified as a gift. The next point is concerned with placing this gift in a scientifically productive context.

Figure 4 reveals the outline for a meta-conceptual model for the field of giftedness research; from the point of view of giftedness research, giftedness is seen as the core of the field. From an *epistemological perspective*, however, this is an insufficient explanation of the genesis of achievement eminence. Further conditions must be met and fulfilled, a process which, in its entirety, will be denoted as a critical state.<sup>1</sup>

<sup>1</sup> The concept of a 'critical state' has already been employed in several branches of science and is referred to as a transitional phase. For instance, the term critical mass in nuclear physics refers to the state a mass is in during a chain reaction induced by nuclear fusion.

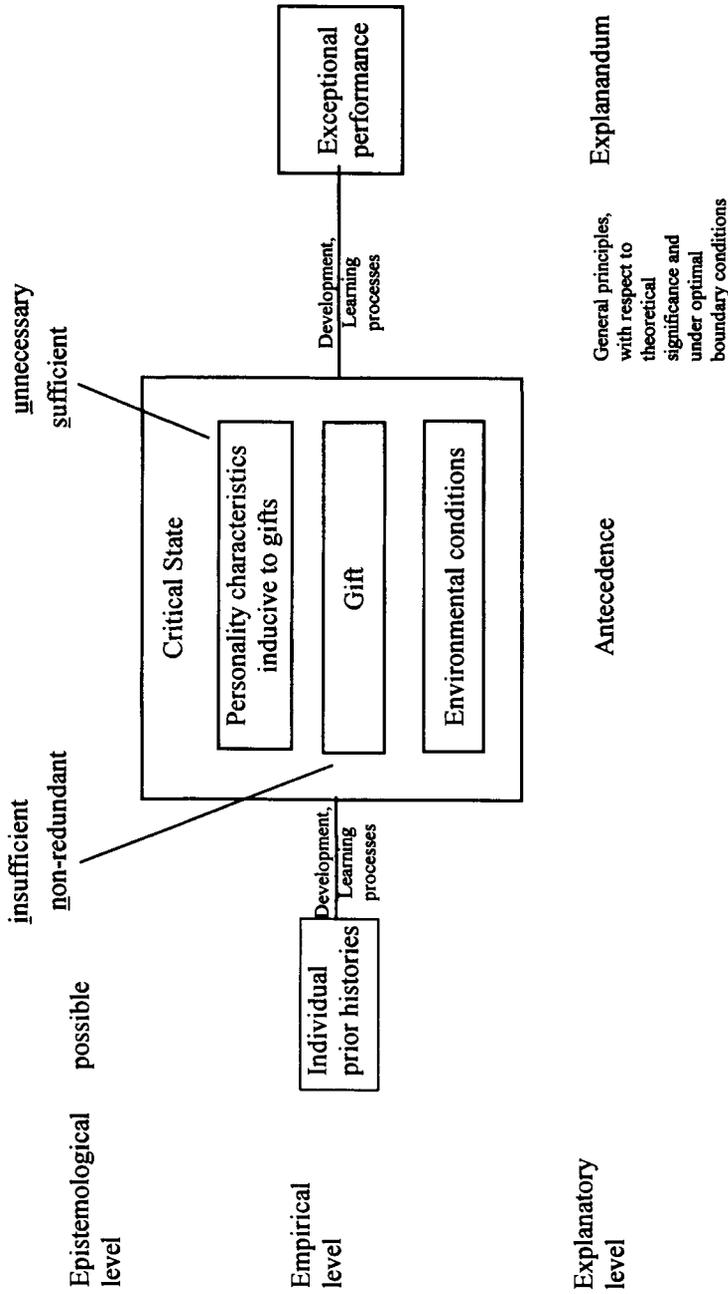

Figure 4. The critical state view of giftedness.

Giftedness, as a part of a critical state, is non-redundant, which legitimizes it as an integral field of research. The critical state, which in addition to giftedness, encompasses environmental and personality factors which promote the development of giftedness is, from an epistemological perspective and when the optimal boundary conditions exist, sufficient for the development of achievement eminence. However, this critical state is not a necessary condition in that achievement eminence can principally be attained via alternative avenues. In this respect, giftedness within the critical state fulfills the inus condition.

The meta-conceptual ordinal diagram illustrates a time span which covers the period preceding and following the critical state. The individual prior history is, from an epistemological perspective, a possible state in which it could very well be that the attainment of a specific manifestation of achievement eminence is already genetically fixed. In this case, it would be useless to consider an individual's prior history.

The eminent achievement can follow the critical state if optimal boundary conditions are present. Developmental and learning processes mediate between individual prior history and critical state as well as between critical state and achievement eminence. This last association must abide by the postulate of theoretical significance.

Let us now look at the model on the *explanatory level* within the framework of the model developed by Hempel and Oppenheim (Hempel & Oppenheim, 1953, cf. Fig. 4, Hempel, 1965). According to their model, an explanation bears three components: first, there must be some statement of a particular fact or facts (antecedence); second, it must incorporate one or more general principles or laws; and third, there must be a statement describing whatever it is that is being explained (explanandum). The explanation shows that the thing to be explained follows from the general principles, given that the particular facts also hold. In applying this to the ordinal diagram at hand, one sees that achievement eminence should be subject to explanation; the entire critical state (not just the gift) describes the particular facts. The general principles correspond to the psychological theory, so that achievement eminence can be theoretically derived from the critical state.

The preceding discourse clearly indicates that the critical state can only be *empirically* identified, and is distinguished for each domain. Thus, it may very well be the case that in one domain the critical state, on the average, can first be attained at the age of 12, while in another domain a critical state has already been reached as early as at the point of conception. In the first domain, all possible combinations of genetic, gene-environment interactions and pure environmental influences could be feasible conditions for the attainment of the critical state (Plomin, 1990; Plomin, DeFries & McClean, 1990), in the second domain,

giftedness was genetically determined. Decisive here is that the critical state view, in principle, offers equal validity to both possible scenarios. First, we must establish that ideological discussions without corresponding evidence in the form of data and without naming the domains in which the gifts are to be identified are more or less futile. Perhaps there is such a thing as a born violinist, but not a born author; conceptions of giftedness must allow for these possibilities.

The critical state also makes no concrete statements regarding what giftedness in a specific domain is; this is a question which must be empirically clarified by each separate domain in and of itself. Certainly, the critical state does not rule out the development of mistakes which could seriously endanger the progressiveness of the field of giftedness research. Let us here consider an example. It is well known that Terman (1925) established his longitudinal study on an intelligence-based operationalization of giftedness. Quite recently, increased theoretical efforts have been undertaken in the area of cognition research to better support cognitive super-constructs such as intelligence. They have been related to low-level biological measures (see Anderson, 1992; Gustafsson & Undheim, 1996, for reviews) such as inspection time (Deary & Stone, 1996), nerve conduction velocity (Vernon, 1987), and evoked potentials (Eysenck, 1988). In another line of research, Kyllonen (Kyllonen & Christal, 1990; Kyllonen, 1996) has shown that there is enough good empirical evidence to accept the existence of a close to perfect relationship between reasoning ability (e.g.,  $G_r$ ) and working memory capacity. However indifferent the endeavors to make intelligence a theoretically more comprehensible entity may be, from the point of view of the critical state, this is possibly the wrong point from which to begin the process of identifying talents. The starting point should be the supported psychological analyses of the behaviors leading to eminent achievement and the developmental conditions conducive to these behaviors. Only then can a gift be identified which also fulfills the criterion of theoretical significance. If, in fact, it can be proven that academic achievements or the development of achievement eminence in the academic area is actually founded on intelligence, then it makes sense to identify the intelligence of a person as a gift. Then factors such as low-level biological measures, inspection time etc. could also be gainfully investigated as potential gifts.

Now, on the basis of the previous expositions, only a few recommendations can be proposed for inclusion into the terminology of giftedness research. *Gifts* should be denoted by those psychologically identifiable factors which: (1) precede behaviors leading to eminent achievement, (2) satisfy the inus condition, (3) describe personal factors and (4) are theoretically significant with respect to the behaviors leading to the eminent achievement as well as its acquisition. The

term *talent* should be used to indicate persons who have reached the critical state. In contrast, an *underachiever* would be a person who has reached the critical state, but has not yet been able to evolve to achievement eminence. Finally, *experts* should refer to those people who have been able to exhibit achievement eminence.

### Special Problems

#### *Explanatory Relativisms*

Most conceptions of giftedness lend themselves to the label of universal theories in that they are applicable to all domains; this also applies to the meta-conceptual viewpoint of the critical state, however not to the critical state's way of viewing giftedness. Here, gifts are always treated as being *relative* to specific forms of achievement eminence, thereby allowing for the express admittance of explanatory relativism regarding gifts. These are dependent on the determination of achievement eminence, or to put it another way, the solutions to the application problem, the focus problem, the reference problem and the significance problem. On their behalf, two aspects are to be emphasized. In the first place, it appears to be improbable that a general theory of giftedness could be established which would be entitled to universal domain validity. The demands made for such a claim by fields as diverse as sports, music and academics appear to be too great. In the second place, the limits of achievement can be altered, which brings about differing solutions for the significance problem, which in itself would lead to a variety of empirical consequences and theoretical implications. In this way, a lofty achievement from yesterday, which was only possible through fixed genetic provisions, may be easily learned tomorrow.

A further aspect of explanatory relativism ensues from the inus condition; a critical state, although sufficient for the attainment of achievement eminence, is not necessary; this implies that achievement eminence can also be attainable through alternative critical states. This seems to be thoroughly plausible and can also be conventionally defended in that in the identification of gifts it is not just one expression of the gift which is used to authorize recognition in domains such as academics, art or sports (Hany, 1993).

#### *Ontological Status of Gifts*

The critical state view proposes the framework for a conceptual model which, in principle, is an uninterpreted model which must be confirmed for every manifestation of achievement eminence. Gifts are empirically ascertainable psychological entities. Therefore, it can be that the emphasis is on one single trait, such as intelligence or a perceptual ability, or on an entire set of traits. At any rate, there is no guarantee that the conceptual model can be interpreted in specific cases, in other words, that a gift actually exists. In case

there is a need to emphasize that a specific form of achievement eminence can be realized through externally controlled learning processes alone, then the domain in question is one in which giftedness plays no substantial role whatsoever.

Likewise, it is important to point out that gifts are not merely predictors, as for instance Heller and Hany (1986) or Ziegler and Perleth (1997) postulated in their prediction models of eminent behavior. The general problem with mere prediction models is their lack of an explanatory status; in order to further clarify this point, we look to another branch of science: astronomy. One can safely assume that a solar eclipse will take place when 99% of all astronomers agree on this prediction; this prognosis does not, however, satisfy the postulate of theoretical significance. By the same token, even a good predictor of achievement eminence, such as intelligence, cannot be automatically identified as a gift as long as the causal mechanism which leads to achievement eminence cannot be confirmed.

In summary, one can conclude that gifts are concerned with psychological personality characteristics or even configurations of such characteristics which must be empirically identified, satisfy the requirements of the four postulates discussed, and demonstrate an empirical correlation to reality.

### Epistemological Perspective

Through the postulate of the inus condition, the critical state view holds various epistemological assumptions which require some clarification. Three aspects are of particular significance, the epistemological terms 'sufficient' and 'necessary', the question of a probabilistic interpretation of the critical state and finally the question surrounding the boundary conditions.

#### *'Sufficient' and 'Necessary'*

The critical state signifies the moment in the biography of a person at which, under specific conditions, achievement eminence will be attained with sufficient certainty. This, however, raises logical problems since there is no guarantee that a person who has reached the critical state will actually demonstrate achievement eminence. For this reason, the application of the term 'sufficient' seems to be too extreme from a strictly logical point of view. Actually, it should not be understood in a strictly logical sense as a description of actual empirical relationships, but rather as a subjective certainty in the estimation of the state by assessors (giftedness researchers, patrons, giftedness program administrators, etc.) of a person who finds him/herself in a phase of achievement development. This subjective certainty is not random, but rather relative to the available psychological knowledge and the available information regarding the ability to meet the conditions essential for fostering the development of achievement. Here, the assessments of the relevant experts will certainly deviate from one another, although the

problem is not unknown. In certain respects, it is similar to the subjective certainty shown in the acceptance of a specific level of statistical error, whereby there is no compelling justification for one to deem a 5% or 1% error rate as being sufficient for the acceptance of a hypothesis. These considerations can effortlessly and logically be translated to the assessment of the term 'necessary'. The expressions 'sufficient' and 'necessary' refer to personal judgments which are based on subjective acceptance criteria which themselves have to be supported by current knowledge in the discipline.

#### *Probability*

The application of the terms 'sufficient' and 'necessary' suggests that the critical state view is concerned with a deterministic view of achievement development. At the very least, the discussions in the last text section should have made clear that this point of view is not intended, and that instead, probabilistic relationships are advocated.

#### *Boundary Conditions*

Scientific statements are only valid under certain conditions, which are referred to as the boundary conditions. In the same manner that a falling stone will be pulled towards earth as long as no obstacle blocks its path, a person who has reached the critical state will only be able to develop achievement eminence under certain boundary conditions. Each and every field of scientific research is faced with the challenge of determining the precise conditions under which their theories are valid; giftedness research is no exception to this rule. What is called for here is an *optimal process criterion*; in concrete terms, this means that we should place strict standards on the conditions of a critical state. The need to adopt an optimal process criterion is founded on the fact that achievement eminence concerns itself with a rare behavioral pattern which can only be mastered by a small minority. The higher the demands for quality placed on the *ceteris paribus* conditions are, the lower the level of achievement will be for a person who has been able to reach the critical state. This does open up the opportunity for theoretical advantages. Gifts are further removed temporally from achievement eminence, whereby more ambitious giftedness theories, as well as theories which secure theoretical significance, become essential. Furthermore, the optimal process criteria leads to an earlier indicator of talents.

#### **What advantages are Offered by the Critical State View?**

##### *Forging a Link to Expertise Research*

One point, which is also of the utmost significance for the further development of the field of giftedness research, is that the critical state view enables the forging of a frequently suggested link between two

areas of research which are often unnaturally separated (Feldhusen, 1998; Sternberg, Gross in this handbook): Giftedness research and expertise research. While giftedness research has traditionally posed the question of where the gifted are heading towards and whether they will ever reach the point of eminent achievement, expertise researchers have always been interested in determining where experts come from. Figuratively speaking, from the perspective of the critical state view, the task of giftedness research is to establish this theoretical link between the talented (who have achieved the critical state) and experts (who have demonstrated exceptional performance).

##### *Empirical, Ontological and Theoretical Criticisms of Expertise Research*

The critical state view furnishes methodological references for the identification of gifts which eases empirical research of giftedness; since they are understood as constructs with an empirical correlate, their identification is, in principle, feasible. They could be referring to, for instance, specific motor characteristics, cognitive or perceptual abilities. Such qualities are already the focus of empirical investigation, and psychologists make a daily practice of placing them under examination.

Through such a consistent empirical point of view, various fruitless arguments such as the previously mentioned debate over the existence of talents or gifts become unnecessary. Whether giftedness is determined through genetics or learning processes (Sternberg & Grigorenko, 1997) becomes a subordinate question from the point of view of giftedness research; it only becomes important when one is investigating the conditions pertinent to the origination of giftedness. A more important and distinctly praiseworthy advantage of a critical state view is the compulsion it generates towards a theory guided style of empirical research.

From an ontological point of view, gifts are accredited with the same ontological status granted to the behaviors leading to eminent behavior. Here, we are referring to neither a composite of items from a list-based definition, nor to simple predictors (although they would provide a useful service), but rather to empirical factors capable of explaining the subsequent process of the development of eminent behavior.

Through these empirical and ontological interpretations of the traditional talent constructs, the above-mentioned meta-theoretical difficulties are avoided. The critical state view guarantees non-circularity, foremost on the grounds of the temporal displacement between the gifts and the behaviors pertinent to achievement eminence. Gifts are also not immune to falsification in that it has already been conceded that for a specific type of achievement eminence, no specific gift may exist. Through the explanatory relativity of gifts, it may very well be the case that a form of giftedness which is acceptable today

may quickly become obsolete due to a redefinition of achievement eminence or advances in promotional techniques. Finally, the demand for theoretical progressiveness (Lakatos, 1978) is serenely met with a critical state view since a close-fitting link between gifts and achievement eminence is demanded, whereby the criterion of theoretical significance, which no longer extends mere predictive services, is easily met.

### Summary

Exceptional performances have always fascinated mankind, but it was only when the theoretical concepts which resulted from empirical psychological investigation were available, that one could replace the theological and metaphysical explanations which have been hitherto pressed into service. It is on the meta-theoretical level that many current conceptions of giftedness need to confront criticism. With the critical state view presented in this chapter, a meta-conceptual model is being delineated which should serve to surmount these deficiencies. The critical state view, although it does not propose a substantive theory of giftedness, does show the manner in which one could be developed in the future on the basis of solid empirical research. Starting with an analysis of the behaviors which lead to achievement eminence, it is proposed that a critical state be established, based on disposable theoretical knowledge and the assumption of optimal conditions for achievement eminence. Within this critical state one can identify those possibly special gifts which meet the criteria developed in this chapter.

### Acknowledgements

The authors would like to thank Hanna David, Letitia Hernandez and Thomas D. Raul for their assistance in the form of critical discussions and valuable comments to an earlier version of this chapter, and Alice Boetsch, Thomas D. Raul and Janet Townsend for their hard work in the translation of the text.

# A History of Giftedness in School and Society\*

Abraham J. Tannenbaum<sup>1</sup>

## Introduction

Does genius make history, or does history make the genius? A seemingly intriguing question for school children and scholars alike. But a deceptive one nonetheless, since the choice is not 'either-or'. Actually, neither individual geniuses nor historical forces predominate, the real relationship being interactive and interdependent. Great ideas by highly creative individuals often carry enough power to influence the course of history; conversely, the *Zeitgeist* (spirit of the times) exercises an enormous influence on great minds and on the domains of excellence in which their precious ideas are generated.

## Western Perspectives on Domains of Excellence

Although the precise manner in which geniuses and their eras inter-relate will always be a mystery, one impression seems clear: the work of seminal thinkers throughout the ages and societies is so important that unless we learn to appreciate it we cannot hope to learn how the human family *makes* history. Indeed, there are historians whose theories are bound up with the nature and impact of creative accomplishments in every historical period.

Spengler (1918), who compared the development of a society to that of a human organism, each with its own life cycle and distinctive personality, believed that every stage of growth is *defined* by the style and

substance of great creative works produced at that time. Medieval Europe is characterized by the Gothic cathedral in architecture, the Gregorian Chant in music, and 'Everyman' in drama, all treasures of creative thinking and fitted perfectly to Church-State political leadership. In the Romantic Period, sumptuous government buildings and elegant homes for the bourgeoisie are the representative architecture of flourishing democracies; Beethoven's music and Shelley's poetry bespeak the idealization of the human collective spirit as it replaces the earlier authority of monarchy and aristocracy and the still earlier power of the Supernatural. It would therefore be anachronistic for a late twentieth-century composer to create music in the style of Mozart's Divertimenti or for an artist to produce a Gainsborough-type 'Blue Boy' in the 1990s. The voices of present-day genius are not only different from those of previous times—they also codify current history as both reflectors and shapers of the society in which *they* live, just as their predecessors did in their own idiomatic, but era-inspired, ways when Western society was younger.

In an essentially different approach to history, Toynbee (1967) emphasizes society's need to respond successfully to periodic challenges as a condition of survival. Today, the most obvious obstacles facing the world include threats to the environment, huge regional pockets of overpopulation and hunger, the dread of nuclear warfare, urban decay and violence, inter-ethnic and inter-class tensions, and a host of diseases that resist cure thus far. Whatever progress is made in confronting these problems will be spear-headed by some of the most advanced thinkers of our times. Toynbee is explicit in estimating the importance of creativity in guaranteeing the survival of Western civilization when he writes:

*To give a fair chance to potential creativity is a matter of life and death for any society. This is all-important, because the outstanding creative ability of a fairly small percentage of the population is mankind's ultimate capital asset, the only one with which Man has been endowed (p. 24, italics in the original).*

---

\* Since the terms 'giftedness', 'talent', 'creativity', and 'genius' appear in this chapter, a brief note is in order concerning their intended meanings. 'Giftedness' and 'talent' are used synonymously to encompass publicly valued abilities possessed by no more than one to two percent of people at each developmental stage. 'Creativity' is regarded here as representing one of two aspects of 'giftedness' (or 'talent'), namely, innovation or invention that deserves critical acclaim, in contrast to the other aspect of 'giftedness' (or 'talent') which refers to highly developed proficiency in highly demanding tasks. 'Genius' is the most advanced extension of 'giftedness' (or 'talent') or 'creativity', denoting Olympian-level accomplishments by the rarest of adults.

In essence, then, there is not only a history of giftedness, but also history *and* giftedness. It makes little sense to recount the life of a people without taking special note of at least some of its best minds. These leading figures produce immortal artifacts that symbolize the distinctive nature of culture and civilization as they are preserved and changed in the course of time (according to Spengler). Viewed differently, the nature and degree of creative thinking are critical in determining whether a culture can survive and continue to grow or become truncated relics of an unrecoverable past (according to Toynbee).

### Historical Drives

The human psyche seems to have a phenomenal potential for achievement. There are no known limits to the *kinds* of talents it can demonstrate and to the heights to which it can climb in any talent domain. But the mind is not motivated to achieve every possible form of excellence. The cultural milieu makes that decision in the broadest possible sense. Spengler suggested that the predominant characteristic of Western society is 'Faustian', a term based on the medieval legendary character, Faust, who is depicted in masterpieces by Marlowe, Goethe, Gounod, Boito, and Thomas Mann. In its reified form, this governing power is said to produce an insatiable urge in individuals to explore the unknown and even the unknowable, to reach the unreachable, to grasp at the fringes of eternity, as it were, no matter what sacrifices are necessary to solve the mysteries of the universe and to serve the cause of aesthetics. Spengler offers no clue as to why the West adopted Faust as its inspiration to thrust ever upward with the Gothic arch in the Middle Ages and into outer space and the firmament in our own time. But according to him, the high-intensity drive has always been there; penetration of the heavens with cathedral architecture in one period of history and with jet propulsion in another era represent similar Faustian impulses emanating from different world views. Both also represent accomplishments of some of the best minds of their respective generations. Thus, the history of a people comes to life and takes on meaning through feats of supreme intellect and artistry in every generation.

In the course of Western history, considerable consensus has evolved concerning domains of excellence that have come to receive highest valuation and emphasis. Phenix (1964) describes these domains from the perspective of a philosopher-educator, as follows:

(1) *Symbolics*, including basic forms of communication through ordinary language, mathematics, and such nondiscursive symbolic forms as gestures, rituals, and rhythmic patterns. These systems are structured according to socially accepted rules of formation and transformation and, as carriers of messages between human beings, they are the most

basic of all realms of meanings since they have to be used to express ideas in each of the other realms.

- (2) *Empirics*, comprising the sciences of the physical and living world. Their content includes factual descriptions, generalizations, and theoretical formulations based on objective evidence in a world of matter, life, mind, and society. Hypotheses introduced into these realms are tested according to specified rules of evidence and verification before acceptable truths can emerge.
- (3) *Aesthetics*, including the various arts, such as music, painting, sculpting, theater, and literary creation. "Meanings in this realm are concerned with the contemplative perception of particular significant things as unique objectifications of ideated subjectivities" (pp. 6,7.).
- (4) *Synnoetics*, derived from the Greek word *Synnoesis*, meaning 'meditative thought', or more specifically, a combination of *syn*, meaning 'with' or 'together', and *noesis*, meaning 'cognition'. Synnoetics therefore signifies insightful relationships between people or psychological understandings about people. It applies to other persons or to oneself in the sphere of *knowing*, just as sympathy relates to individuals in the sphere of *feeling*.
- (5) *Ethics*, which emphasizes moral meanings that are concerned with *obligation* instead of fact, what ought to be rather than what was, is, or will be. "In contrast to the sciences, which are concerned with abstract cognitive understanding, to the arts, which express idealized aesthetic perceptions, and to personal knowledge which reflects intersubjective understanding, morality has to do with personal conduct that is based on free, responsible, deliberate decision" (p. 7).
- (6) *Synoptics*, which embraces meanings that integrate history, religion, and philosophy comprehensively. The tools for building such meanings are empirical, aesthetic, and synnoetic, and the outcomes are new insights that amount to more than the sum of the parts from which they are derived.

Psychologists observing the trained and habituated skills in modern Western society classify human aptitude structures in fairly much the same way as Phenix does, albeit from a different vantage point. For example, DeHaan and Havighurst (1957) list the following domains of excellence:

(1) *Intellectual ability*, which is related most directly to success in school subjects, encompasses the verbal, number, spatial, memory, and reasoning factors of the primary mental abilities. Combinations of these aptitudes are regarded as basic to other talents, such as fine arts, social leadership, science, and mechanics.

- (2) *Creative thinking*, which is revealed through some complex mental powers, such as the ability to recognize problems, to be flexible in thinking, to originate ideas or products, or to find new uses for old objects and materials.
- (3) *Scientific ability*, including skills in the use of numbers and algebraic symbols, arithmetic reasoning, curiosity about the natural world, and facility with the scientific method.
- (4) *Social leadership*, specifically the ability to help a group reach its goals and to improve human relationships within a group. Such skills are necessary for those who will eventually assume leadership positions in business and industry, labor unions, professional organizations, community groups, government, and international agencies.
- (5) *Mechanical skills*, otherwise known as 'craft skills' and closely related to talents in the fine arts and in science and engineering. Success in this category depends on manipulative facility, spatial ability, and perception of visual patterns, details, similarities, and differences.
- (6) *Talents in the fine arts*, which are required of artists, writers, musicians, actors, and dancers.

In a similar vein, Gardner (1983) lists seven human intelligences: (1) linguistic, (2) musical, (3) mathematical, (4) visual-spatial, (5) bodily kinesthetic, (6) social-interpersonal, and (7) intrapersonal. What is noteworthy about Gardner's theory is that it derives partly from his observations of individuals who had sustained injuries in different parts of the brain. This source of data is a far cry from the primarily cultural and historic corpus of material from which Phenix (1964) drew his observations. Yet, the overlap in their domain listings is extensive enough to give a clear picture of what is generally recognized as the major types of excellence treasured in modern Western civilization, in contrast to earlier times in the West and to present-day life in some Western subcultures and in parts of the world that remain relatively untouched by Western influence.

Among the talent domains that define the West's particular brands of Faustian strivings, there seems to be something of a prestige hierarchy which has remained fairly stable over the years. Highest in valuation are the *scarcity talents*, so called because they are always in short supply. Medieval society could never get its fill of leadership and inspiration from the clergy who created an orderly, protective environment and provided its constituents with keys to personal redemption from sin and from the threat of divine retribution. In our modern world there is also an insatiable need for people inventive enough to make life easier, safer, healthier, and more intelligible. But hopes for survival are no longer vested primarily in special talents possessed by leaders of the clergy. Instead, the creative scientist and social leader are seen

as most indispensable, and therefore the demand for them cannot be satiated as long as life itself is vulnerable to extinction or dysfunction.

Although it takes only a single Jonas Salk to achieve the breakthrough in conquering polio, there can never be enough talent like his for the great leaps forward that still need to be made in medical science. The same can be said for an Abraham Lincoln in political leadership, a Martin Luther King Jr. in race relations, a Winston Churchill in defense of human freedom, and a Sigmund Freud in mental health. Society will always venerate such talents as they appear, while thirsting for more and more since the shortage can never be filled, principally because the public's motives are more self-preserving than self-serving. It makes sense, therefore, to consider these special abilities as symbols of excellence in greatest demand.

Ranking second are the *surplus talents*, so named because their cumulative accomplishments over the years are so abundant, rich, and varied that they exceed the capacity of individuals to sample and derive benefit from all of them. For example, it is said that multitudes acknowledge the greatness of Dante for his *Inferno*, but hardly anyone ever reads it even once in a lifetime. For the non readers, such a masterpiece is considered 'surplus' in the sense that it is underutilized as literary fare, although it could never be considered 'superfluous' inasmuch as some people, albeit a handful, do read and adore it.

Those who possess surplus talents have the rare ability to elevate people's sensibilities and sensitivities to new heights through the production of great art, literature, music, and philosophy. Few individuals can excel in this category, and some who do achieve celebrity status, which means that they are the most widely recognizable people in the eyes of the general public. But despite the fame and fortune of a Picasso and a Beethoven, they are treated as 'divine luxuries' capable of beautifying the world without guaranteeing its continued existence. Of course, a Michelangelo and a Bach are always welcome as cultural assets; still, the need for such talents represents a *craving* for ways in which to enhance the quality of life rather than a *demand* for finding means of preserving life itself. People are more likely to suppress their cravings than their demands, as evidenced by the vast treasures of art, literature, and music that are widely unappreciated.

The terms *scarcity talents* and *surplus talents* are not intended to express value judgments, as if one were superior to the other. They are simply different in the *kinds* of admiration they elicit from society and in the popular hierarchy of importance if a choice between them had to be made. Scarcity talents are treated as if they were vital human resources that will always be in short supply as long as utopia is yet to be attained. Their primary preoccupation is with fathoming the unknown and even the unknowable, and modern Western society has committed itself to investing all it

can to further such an enterprise. The physical survival of individuals depends on the existence of scarcity talents, whereas the cultural survival of the civilization depends on surplus-type talents. Therefore, it is no surprise that many schools and their supporting communities are more eager to cultivate scarcity talents in order to keep body and soul together rather than to nurture surplus talents for the sake of keeping the human spirit alive.

Third in rank are the *quota talents*, which include specialized, high-level skills needed to provide goods and services for which the market is limited. The job to be done is fairly clear; there are no creative breakthroughs expected and no way of knowing precisely how long the opportunities for such work will last. Job openings for the relatively few who qualify depend on supply and demand, which can be irregular and geographically bound. Thus, a person with aptitudes for local political leadership has a chance of becoming elected only on special days designated for voting in a democracy, provided that an appropriate vacancy in public office exists at that time. Physicians, teachers, engineers, lawyers, commercial artists, and business executives are but a few of the kinds of highly skilled people whose work is valuable. But they are sought after only in response to market demand and opportunity. Sometimes there are low supplies of such talents, as the case of physicians needed in poverty-stricken areas of the world; occasionally there are surpluses, such as liberal arts PhDs who are working at unskilled jobs because they cannot find professional employment for which they are trained, even though some positions are filled by less capable people hired ahead of them and protected by tenure policies.

Like scarcity and surplus talents, quota talents emerge in response to popular demand, but only up to the point where the public feels that its needs for such productivity are being met. For example, major symphony orchestras are kept alive by appreciative audiences that support first-rate performances by first-rate musicians. Sometimes there are vacancies to be filled in orchestral sections, and the search is on for candidates who qualify. But the number of such positions is necessarily limited by the number of orchestras the public is willing to sponsor. Hence, there is a quota system against which to measure shortage and surplus.

Schools have historically been most responsive to the public's needs for quota talents. These types of advanced skills are appreciated for the specialized services and goods they supply and for their market value. Schools can therefore be alerted to areas of expertise where there are many openings and the pay is good for those who are bright and trained enough to qualify. In many schools, the advanced training programs designed to fill quotas in various professions have traditionally constituted the total effort at differentiating education for the gifted.

Ranking last in the hierarchy are *anomalous talents*, including those which are either unappreciated or disdained. Yet, they reflect how far the powers of the human mind and body can be stretched and still not be recognized for excellence. Included among them are many prodigious feats, some having practical meaning, others being appreciated for the amusement they provide, and still others that strike fear and awe in people. Speed reading, mastery of mountains of trivia, gourmet cooking, trapeze artistry, performance of complex mathematical calculations faster than a computer, and even the numbers of sexual seductions boasted by a Doan Juan are just a few examples of such talents. In this category there are also 'extinct' abilities such as oratory and various types of manual craftsmanship that belonged among the scarcity, surplus, or quota talents in another era, but can now be considered anomalous because they have become anachronisms. The condemned talents include the demagoguery and craftiness of a Hitler or a Stalin, which may require as much ingenuity as do extraordinary leadership skills for constructive purposes, except that they are threats rather than boons to humanity.

Schools have habitually emphasized the development of harmless anomalous talents, especially those that attract crowds and build morale, such as sports, glee clubs, and marching bands. The popularity of such activities among students and alumni, especially in the United States, is communicated to faculties who respond by mounting elaborate talent hunts and devoting considerable effort to sharpening these talents.

Thus we see that scarcity, surplus, quota, and anomalous types of giftedness have always been valued differently by patrons of excellence. The four categories may encompass all forms of giftedness, but the differential categorization helps describe, if not fully explain, their differential acceptance.

#### *Historical Constraints*

In his psychoeconomic approach to the study of creativity, Rubenson (1992) weighs the intrinsic and extrinsic costs as well as benefits of innovation in different historical periods. The intrinsic costs refer to the pressures on creative minds who, by virtue of their inventions and discoveries, render obsolete at least some cherished wisdom that had also been innovative at one time and had also upset established dogma before gaining acceptance. Indeed, iconoclasm and revisionist thinking is likely to meet resistance which can exercise restraint on the impulse to create, or even demoralize it. But the countervailing, if not overpowering, drive is toward newness, which is seen as progress in some domains of excellence and venturesomeness in others. Among the sciences, changes in theory often meet the stiffest objections from those who have mastered and adopted older concepts, but eventually the change is accepted as progressive. For

example, Galileo's proposition that the sun is immovable in the center of the universe and that the earth has a diurnal motion of rotation has long been seen as a major breakthrough in astronomy. Yet, Galileo languished in what amounted to house arrest for the last eight years of his life because his theories were considered heretical.

It is awesome to contemplate how much richer and more abundant the West's cultural treasures would be if countless potential geniuses had not elected to suppress or abort their creative impulses because they feared ostracism or even reprisal if they would dare revolutionary style and substance in the world of ideas.

Unlike intrinsic costs, which relate to the creative person's courage (or lack of it) to render received wisdom obsolete, extrinsic costs focus on societal influences that stimulate (or inhibit) creative activity. Obviously, freedom of expression encourages daring, avant-garde thought and productivity. Coupled with liberty is the impact of opportunity and access to audiences, clients, and customers. Rubenson (1992) cites evidence to show a relationship between the number of journals in an academic domain and research output by discoverers in that discipline. He also refers to patent data to measure how changes in demand can affect the frequency of invention. It is not just demand that makes a difference; patronage and sponsorship do also. And the effect is not only on quantity, but also on fashion and content of creative products. Simonton (1990a, b), for example, lists many instances where ingredients of musical and literary products relate directly to variations in external demand. How else to explain the special Russian thematic material—and indeed the very existence—of Beethoven's *Rasumovsky Quartets* without reference to their being subsidized by the person to whom these works are dedicated, and to his native origin?

The combination of personal freedom and encouragement would seem to create historical imperatives for the production of excellence. That is, times and places which provided these conditions should have been rewarded with a flowering of genius, whereas under oppressive and restrictive conditions the landscape of creativity would be expected to remain barren. However, here is an instance where logic and reality are not always compatible. Somehow, the human spirit that is strong enough to overcome internal restraints is sometimes able to survive and even create under brutal political regimes.

True, a Werner Von Braun could develop his considerable talents even in a police state under Hitler because his own Nazi convictions may have given him access to opportunities for cultivating and dedicating desperately needed talents in rocketry to help the German war effort. The same may apply to the multi-talented Albert Speer, whose superior abilities together with his deep loyalty to Hitler enabled him to design an enormously productive slave labor operation, as well as

a vision of a Third Reich capable of maintaining its hegemony for a thousand years. But how to explain the genius of an Osip Mandelstam, who wrote great poetry while declaring his enmity toward Stalin, which eventually led to his death by order of that tyrant? How did he, and his wife Nedezhda too, manage to achieve immortality for their literary works while suffering so much oppression and humiliation in their native country? Perhaps Amabile (1983) and Hennessey and Amabile (1988) are on target when they reveal the enormous power of intrinsic motivation in creative work. Indeed, it may even be strong enough in some cases to overcome the pain of extreme adversity.

The emphasis has to be on 'some cases', to point up the fact that wide generalizations cannot be drawn from them in any view of history. More typical are the consequences of changes in political leadership in late fourteenth- and early fifteenth-century China. As Mokyr (1990) points out, before the fourteenth century, Chinese technology was clearly superior to that of the West in textile production, ship building, the measurement of time, movable type printing, the invention of the wheelbarrow, and the development of chemicals for explosives, pharmaceuticals, and insecticides. In fact, it would take the West several centuries to catch up with some of these technological feats. Artistic technique and imagination were similarly encouraged to flourish as China was approaching the fourteenth century. Grousset (1959) attributes this outpouring of creative productivity to the climate of cultural freedom, and probably public appreciation as well.

But as the Ming Dynasty came into power in the late fourteenth century, support by the ruling elite shifted away from technological and artistic creation to more immediate economic needs. Instead of emphasizing innovation, the regime urged imitation of the past. It also blocked the development of letter alphabets, preferring instead to stay with the old ideograms, which fostered artistic activity through calligraphy but stifled literary excellence for many years. Thus it appears that a relaxation of political policing of cultural life, together with a powerful popular thirst for excellence, helps account for periodic outbursts of greatness in different localities. These conditions were surely prominent in the early sixteenth-century Florence of Leonardo Da Vinci and Michelangelo, the late sixteenth and early seventeenth-century London of Shakespeare, Milton, Bacon, Jonson and Donne, the nineteenth-century Vienna of Beethoven, Schubert, and Mahler, the late nineteenth- and early twentieth-century Paris of Cezanne, Matisse, Monet, and Picasso, and the nineteen-twenties' Weimar Republic of Wedekind, Reinhardt, Thomas Mann, and the Bauhaus.

In a grotesque expression of political and public frenzy to generate progress, especially in science, nations at war can be 'credited' with 'inspiring' breakthroughs meant for human destruction but turned into major blessings for people at peace. Examples

abound in the wake of World War II, but two obvious ones come to mind immediately. The first, of course, is the Manhattan Project, which brought together some of the world's greatest scientific minds to create an atomic bomb, and that in turn ushered in forever the real and potential peaceful benefits of nuclear energy. The other is experimentation with jet propulsion of bombs over Britain by Germany's scientists at Peenemünde, which paved the way to today's jet travel and space exploration. And who can gainsay the countless benefits to modern medicine of treatment drugs, devices, and methods developed originally for use on the wounded in battle? On the other hand, wars have destroyed, crippled, exiled, demoralized, and misdirected so many creative spirits that the discoveries and innovations gained in wartime, dramatic as they may be, cannot possibly make up for the real and potential talent lost in the upheavals of conflict.

Disastrous living conditions around the world have also brought scientific breakthroughs in recent decades. Witness, for example, the so-called 'green revolution', with its outcropping of agricultural abundance, thanks to new methods of selecting, planting, and fertilizing crops to produce enough surplus edibles to feed famine stricken areas of the world. But unfortunately, the magnitude and effects of famine clearly overwhelm the benefits of a green revolution in making enough of a difference worldwide. There are now some three billion people who have no easy access to fresh water, and millions of them live in arid climates, mostly in the southern hemisphere where the once fertile land is already, or is becoming, desert-like in its failure to yield any crops to sustain human life. Aside from the unspeakable misery that exists in that part of the world, there is the added tragedy of a scarcity of talent, brought on by the need to alleviate suffering which saps all energies, physical and mental.

Until the late eighteenth-century, starvation also threatened the lives of many settlers in the North American continent, and artistic life had to be compromised accordingly. But the settlers had brought with them from Europe a social legacy which eventually evolved to what Laski (1948) calls "the quintessence of a secularized puritanism" (p. 42). Its origins are in the familiar Protestant ethic (Weber, 1948), but is applied singularly to the North American condition. It extols effort and the belief that success is its inevitable consequence. In a pioneering society, it is praiseworthy to take risks, show courage, innovate and adapt, and even engage in 'rugged individualism' to build and maintain a modern society. It takes so much ingenuity and hard work to get the job done that there is hardly much time to cultivate the arts. Indeed, artistic life is a luxury that few can afford when so many shoulders have to be put to the wheel.

Only later, when the pioneering days in America were over and political, social, and economic institutions were established, could increasing numbers of

people allow themselves to turn to the life of the mind. Great political theory and science flourished earliest in the post-pioneer years because they were rooted in the necessities of the pioneer period; great drama and music began to appear much later, also as symbols of hard work and self-perfection in conformance with the Protestant ethic. However, in too many parts of the southern hemisphere, where survival is constantly under threat, and living conditions are indescribably brutal, any confidence people may have had in their ability to overcome adversity has been buried beneath layers upon layers of tragedy accumulated over generations. If they ever inherited a belief in achieving excellence through hard work, their histories of abject misery *despite* hard work could only have had a demoralizing effect on them. And yet, faith in oneself and in the perfectibility of the world are prerequisite to creative activity that is of great value. Sadly, there are too many people today, especially in the southern hemisphere, whose life circumstances deprive them of such basis and deny them access to membership in a global circle of immortals.

### Ancient Origins of Interest in the Gifted

Western society has generally looked to Ancient Greek (i.e. Athenian) and Judaeo-Christian traditions for sources of its own cultural identity. In following this practice, a reviewer of history of/and the gifted must beware not to view these forebears as child-like in their mental powers compared to the mature moderns simply because the age of the human species is older now and therefore presumably wiser. True, today's storehouse of music, art, literature, and scientific knowledge is much greater than ever before, a fact that makes contemporary Western society culturally richer than that of Ancient Athens, Judea, or Babylon. But for sheer intellectual power, and the ability to achieve immortality in creative production, the ancients could easily match the moderns in domains of excellence that were characteristic of their societies.

#### *The Legacy of Athens*

In the case of Athenian culture, the talent domains were fairly much the same as those which would eventually be valued in the West. They include intellectual ability, often expressed in philosophic speculation, moral excellence, political insight, literary, musical, oratorical, and artistic talents, as well as physical strength for beauty's sake. Hellenism also spread its influence to Ancient Rome and, indeed, to much of the Middle East long before it took hold in Western countries.

There was no state-sponsored education at any level in Athens, even though Plato advocated its establishment. Instead, private citizens opened schools for boys, ages 6 to 14, or to later ages for those who could afford it. (Girls studied at home where their mothers or nurses taught them how to weave, spin, embroider, sing, dance, and play an instrument.) The boys' course of

study was divided into three parts: writing (including arithmetic and reading), music, and gymnastics. In Aristotle's time, drawing and painting were added. Everyone learned to play the lyre, and much of the instruction emphasized creating music and poetry. Although no time was spent on acquiring foreign languages, great care was taken in learning the correct usage of the mother tongue. Gymnastics were major features of the curriculum, especially wrestling, swimming, and the use of bow and sling. By age 16, the boys were well trained to run, leap, wrestle, hunt, drive chariots, and hurl the javelin, skills needed for military service. When they became soldier youths at age 18 they learned and practiced the skills of democratic governance and engaged in intensive studies of literature, music, geometry, and rhetoric before being sent off as 19-year-olds for a two-year assignment to a frontier garrison to protect the city.

For advanced study, Aristotle, who was recognized in his time as a philosopher, scientist, and statesman, established the Lyceum, a major learning center rivaling the Academy and the School of Isocrates. All three became severe competitors until they began to emphasize different courses of study. The School of Isocrates concentrated on rhetoric, the Lyceum on natural science, and the Academy on mathematics, metaphysics, and politics. At the Lyceum, Aristotle assigned his students to gather and coordinate knowledge in many fields: the customs of barbarians, the constitutions of the Greek cities, the chronology of victories in the Pithian Games and in the Athenian Dionysia, the organs and habits of animals, the character and distribution of plants, and the history of science and philosophy.

Athenian citizens, mainly the well-to-do aristocrats, could thus provide their sons with an education that came reasonably close to Plato's version of special enriched schooling for so-called Guardians, or men of silver, whose performance in advanced studies would determine who qualifies as a man of gold, or philosopher king. Plato believed that citizens in his republic should be trained to maximize their potentialities. He insisted that young men who possessed unusual mental ability, based on evidence derived from various tests, be separated from those of average intelligence and given a specialized type of education. The program would require mastery of science, philosophy, and metaphysics. Those who excelled in the program would form a pool out of which future leaders of the state could be drawn. Plato was convinced that Athenian democracy could sustain its greatness only as long as it provided the best educational opportunities for selected young people who would then become its future leaders.

The Classical idea of a ruling elite based on wealth and merit is anathema to modern Western democracies and has been effectively satirized by Young (1959) as a portent of social upheaval and possible disaster.

However, Athenian tradition highlights the need to nurture human excellence for its own sake and for the betterment of life in society, an ideal which should be made attainable without sacrifice of egalitarian principles. Classical society also calls attention to domains of excellence which came alive during the Renaissance period in Europe and which are so very much alive today in the entire Western world.

### *Judaic Influences*

The Jewish people have often been called 'children of the book', with a tradition of studying, creating, interpreting, teaching, and disseminating ideas wherever they have lived in Western countries. This intense devotion to learning, which has spread its influence to the larger Western community, can be found in several biblical sources, of which the medieval Jewish philosopher, Maimonides, in Chapter 2 of *Laws of the Study of Torah (Mishna Torah)* singles out one: 'The Torah which Moses commanded us is a legacy for the congregation of Jacob (i.e. the Jewish people)' (Deuteronomy, 33:4). *Torah* encompasses a vast literature, including the Old Testament, Mishna and Talmud (i.e. codifications of centuries of Rabbinic exegeses of scriptural law, lore, and philosophy), along with the wisdom and scholarship of *Gaonim*, *Rishonim*, and *Acharonim*, leading exegetists of post-Talmudic times to the present day.

Maimonides' extolling the centrality of *Torah* learning in traditional Jewish life deserved some explication because it reflects the pronouncements of generations of scholars before him, and his influence has remained powerful, even in large segments of today's Jewish world. Here are just a few examples of his thoughts on *Torah* studies:

- (1) There is no biblical positive commandment that outweighs the study of *Torah*.
- (2) *Torah* should be studied for its own sake (i.e. self-betterment and enlightenment), not for the sake of material reward.
- (3) Even if economic circumstances reduce persons to sustain themselves on bread and salt and on severely limited measures of water, and they are forced to sleep on the ground, they may not renounce immersion in *Torah*.

Religious Jews throughout their history have devotedly adhered to the sentiments expressed by Maimonides. To achieve the status of a *Talmid Chachum* (literally a student-scholar)—everybody a student, including the scholar—was an incomparable accomplishment in early Jewish history and remains so to this day. Not even material wealth could gain so much public veneration for its possessor. Indeed, the rich have often sought the brightest, most scholarly young bachelors for possible marriage to their daughters, and the promise of a substantial dowry could enable the groom to spend a lifetime in *Torah* study free from want, even

while building a family. There is never any thought of using the money to enter the business or professional world, or even to support a luxurious lifestyle. Young women had no such educational opportunities until the early twentieth-century when seminaries were opened for them in various Western countries and have multiplied ever since, rapidly in recent years.

Usually, the male's advanced academic work is conducted at a *Yeshiva* (Torah Academy) where partners or small groups of three or four adolescents or adults study together for up to ten hours a day and attend regular lectures by leading student-scholars. Since there is no end to the breadth or depth of study, there is no completion of coursework and therefore no diplomas or any other material awards granted, or even sought, except for the few—not necessarily the brightest—who are ordained as Rabbis after some years of prescribed study, and they serve in pulpits, or in Jewish education, or in community leadership positions. This kind of intensive learning that begins soon after the cradle and extends to the grave has permeated large pockets of Torah-loyal Jewish life in every Western country where Jews have settled, since the destruction of the Temple in Jerusalem in AD 70.

When the male child enters the *Cheder* (i.e. a Jewish school containing one or more classrooms), with much joy and celebration, often as early as age 3, he quickly develops literacy in the Hebrew language and then spends most of the time, until the pre-adolescent years, mastering the scriptures and the accompanying commentaries. Thereafter, for the rest of his student years at *Yeshiva*, including the many informal learning periods outside of school hours and beyond the school years, most of the concentration, by far, is on the Talmud and its vast collection of related literature. His deep penetration into Judaic jurisprudence and codes of behavior requires a most sophisticated level of logical insight simply to understand the text, let alone to draw brilliant inferences from it. The highest honor bestowed by learned peers and even by the uneducated public is upon the rare student who can gain intimate familiarity with Talmudic thought in all its depth and breadth and can also create original interpretations that illuminate it as perhaps never before. This gifted individual thus qualifies as a student-scholar, the person for whom the *Yeshiva* is primarily meant to exist. In short, it is an educational system that fosters a kind of intellectual elitism in which the Talmudist *par excellence* reigns supreme.

Since Jews lived for many centuries as second class citizens in Western society, their Gentile neighbors were rarely inspired by the Jewish love for learning. In fact, some of the richest, most intensive scholarly activity took place in ghetto-like settings, small town (*Shtetl*) communities where religious oppression and separatism was greatest, and there was little desire or even opportunity for Gentile to emulate the often-hated Jew. It was not until the emancipation proclamations all

across Europe and in the United States, mostly in the late eighteenth and early nineteenth centuries, that ghetto life began to crumble as Jews were given freedom to prosper in financial centers and to participate in Western cultural life. From that time on, a huge majority of 'children of the book' (i.e. *Torah*) became children of *all* books. The devotion with which Talmudic study was pursued shifted, for a vast majority of Jews, to secular learning, with far-reaching consequences for the Jewish *Shtetl* and for Western society in general.

The *Shtetl* lamented the hemorrhaging of religious commitment and Torah learning among its youth, while Western society gained a talent pool that enriched cultural life immeasurably and permanently in virtually every domain of advanced-level activity. Unreconstructed anti-semites have derided highly motivated, high achieving Jewish students as grindingly over-ambitious as they scramble and compete to get ahead. So conspicuous have these students been in their self-sacrifice for mastery, that the American novelist, Thomas Wolfe, whose university classes contained large Jewish enrollments, once described them as 'burning in the night' with a seemingly endless fire of enthusiasm for matters cerebral and secular.

For sheer volume of great Western achievements in the arts and sciences over the past two centuries, Jews have contributed far out of proportion to their numbers within the general population. Such immortals as Freud, Einstein, Kafka and von Neumann, among others, even succeeded in revolutionizing whole domains of productive activity far beyond their lifetimes, possibly for all time. Others, though lesser lights, have enriched cultural life in the West not only as creative contributors but also as patrons, mentors, and role models by enabling others to achieve renown while remaining virtually unknown themselves. The magnitude of Jewish constrictive involvement in Western arts and sciences can only be a matter of conjecture, the few hints coming out of facts concerning pre- and post-Holocaust Europe. Engelmann's (1984) powerful treatise on Germany without Jews reports on their critical role in German medicine, politics, higher education, artistic, literary, theatrical, and musical life, and even in that country's record in winning Nobel prizes. The precipitous drop in quality and abundance of German talent since the liquidation of almost all Jewry in that country illustrates how a life of the mind among ancient Jews, passed on from generation to generation, plays a vital role in the recent history of giftedness in Western society.

#### *Christian Influences*

To the extent that Christianity is rooted in Judaic sources, it has also extolled studiousness and achievement, concentrating in its early history on the scriptures, including the New Testament. When it was

at its peak of power during the Middle Ages, it created an everlasting learning tradition without causing Europe to be “blissfully ignorant of the ‘spell of the classics’ and interested only in theological speculation” (Lamonte, 1949, p. 553). Great ideas in science, law, literature, philosophy, and art were, in fact, studied and propounded vigorously at that time. Yet, to the modern Westerner, Medieval Europe appears as a tradition-oriented society in which high-level talent was devoted primarily to the preservation, understanding, and enhancement of Church ideals.

Among the most significant developments in creative thinking by the end of the fifteenth-century, besides ideological treatises, were those associated with early technology and the renaissance. Advances in the chemistry of ink, skills in paper making, and metallurgy enabled Gutenberg to invent movable type sometime around the mid-fifteenth-century, and this new device almost immediately facilitated the wide dissemination of ideas, some of them highly critical of the Church. Among the most powerful polemics were Martin Luther’s ninety-five theses which he nailed on the door of the Castle Church at Wittenberg, Germany, in 1517, a document that received wide circulation with the help of movable type. The theses bitterly attacked the Pope’s practice of selling indulgences, whereby sinners were promised forgiveness if they sent substantial sums of money to the papal treasury. Luther was branded a heretic, but the authority of the Vatican was shaken, not only in his native Germany, but also in France and Switzerland, where John Calvin led the struggle for Church liberalization soon afterwards. These three countries were already leaning toward reformation, so they provided fertile ground for the sowing of new ideas by Luther and Calvin.

With the advent of the Protestant Reformation came the movement toward widespread growth of literacy. Protestants suggested that the masses can serve their religion directly without relying heavily on Church intermediaries. But in order to do so, everybody had to be able to read and understand the scriptures. True, it requires hard work, but the rewards are substantial, since human beings are considered perfectible through their own efforts, according to Protestant tradition.

The growth of the Protestant spirit and ethic over the past five centuries, and the conversion of the Western world from an agrarian to a highly commercial and industrial society have exerted deep influences upon present-day concerns about the development of talent. In the Protestant urban centers the individual quickly learned that the highest rewards in life could be attained through self-enlightenment and self-betterment in some culturally approved area of activity. This orientation to life’s opportunities brought with it the seeds of universal education, scientific and technological development, and intense intellectual restlessness that conforms with the Faustian nature of Western society.

Reinforcing the spirit of reformation and humanism was the contemporaneous renaissance movement, which vitalized creative behavior through new freedom of style and substance. Although the Church and its sages retained their prominence in the art of Titian, Tintoretto, Michelangelo, and El Greco, among many others, these masterpieces reflected an inspiration to idealize the human form and to place the human being at center stage as divinely conceived and precious beyond measure. The powers of reason and the senses gained new respect as they brought back to life the Greek and Roman Classics. The scope of the new enthusiasm for learning widened rapidly, incorporating in it a need to advance the sciences for a better understanding of the laws of nature, of the structure of the planet, and the place of the planet in the wider universe. It was a break from the past in which intellectually gifted behavior was dominated by logicians trained in scholastic disputation and in speculating mostly about the human soul that was often shrouded in mysticism. The Renaissance replaced mysticism with humanism and its belief in the goodness and dignity of the human species, as well as its great powers of thought and imagination, as evidenced by the wealth of ideas inherited from the ancient Greeks and Romans.

### **The Modern Scene**

The Reformation and the Renaissance eventually led to the industrial revolution which further reinforced belief in human potential for fashioning a new world with better-than-ever standards of living and qualities of life. Understandably, the public bestowed renown—sometimes fortune, too—upon those who excelled as conquerors of nature through science, producers of masterpieces, and masterful performance on the stage and in various professions. The names associated with these great achievements took on an importance of their own, sometimes exaggeratedly so, when the so-called ‘Matthew Effect’ drew critical accolades for inferior work simply because the high reputation of its creator had been earned through earlier success. Fame, or at least recognition among peers, became a powerful spur to self-fulfillment and self-advancement and remains to this day a prime incentive for potentially gifted people to fulfill their promise.

As popular belief in the powers of the individual and in opportunities for individualism grew over the past two centuries in Western countries, so did democracy as a preferred social system and form of government. Egalitarianism and excellence emerged as ideals to be preserved, even though they have always been counterpoised and resistant to reconciliation. Among the democracies there are constant changes and variations in emphases on people’s rights to social, political, economic, and educational entitlements, especially those individuals who are poor in status and in finances. A democracy that leans far in the direction of

egalitarianism seems to weaken its commitment to excellence and is therefore in danger of losing honor in the family of nations—a threat from without. On the other hand, a strong commitment to excellence can compromise equality of status and opportunity within a democracy and arouse serious civil unrest—a threat from within.

Examples of both kinds of threat seem to surface from time to time in modern Western history. Conscious efforts to foster excellence could be seen under the benevolent monarchy of late nineteenth-century Austria, which was determined to maintain its status as one of Europe's premier cultural centers. At that time, secondary education was of a kind that some of today's educators would consider elitist. The famous literary figure, Stefan Zweig, was then a student at a Viennese *Gymnasium*, along with others from bourgeois families, who could afford the tuition and who were bright enough to qualify for pre-university studies. In his autobiography (1943), Zweig described his *Gymnasium* as an eight-year program, following five years of elementary school, and requiring French, English, and Italian (the 'living' languages) along with Greek and Latin ('dead' languages) plus geometry and physics, among other subjects. In more egalitarian democracies, the Viennese program would perhaps qualify as differentiated education for the gifted, since the mainstream curriculum is geared to accommodate students who are closer to average in ability, many of whom have no plans to enter college.

In a fairly unusual situation where commitment to excellence is a national priority, one may consider the relatively short history of education for the gifted in Singapore. A city-state established in 1965 as an independent, Western-oriented democracy, it has adopted English as its official language and geared its educational system as a means of finding a place in the economic and cultural atmosphere of the much larger, more established Western nations. Law and order are strictly enforced, efficiency and proficiency are emphasized, and there are relatively few special educational provisions for handicapped learners. However, the academically gifted are placed in special programs which provide advanced-level studies in English language and literature, the maths and sciences, foreign languages, history, geography, social studies, moral education, and computer appreciation. Australia's commitment to the gifted, on the other hand, varies according to the social ideologies of its states. In Victoria, where there is a relatively strong emphasis on egalitarianism, political office holders tend to resist singling out the gifted for special enrichment experiences. They would rather 'cut down tall poppies' to equalize educational opportunity than adjust curricula to accommodate individual differences at the upper ability levels. As a result, proponents of special enrichment for the gifted have had to struggle hard, with only occasional success, in influencing public

policy. Not so in New South Wales, where egalitarianism seems to be a less sensitive issue and where there is more eagerness to single out the gifted for special studies.

It should be emphasized that modern Western democracies have always paid attention to the needs of the gifted, albeit with various degrees of intensity. From 1917 until Hitler came to power, Germany made some efforts on behalf of precocious children. Special schools and classes with enriched curricula were formed on the basis of psychological tests. France, Great Britain, Belgium, and Switzerland also have a modern tradition of identifying and training gifted children, or at least providing support for their continued advancement up the educational ladder. However, none of the democracies invested as heavily as did the dictatorships, which considered the gifted as vital human resources for furthering the power of the state. In its early period, the Soviet Union's overall curriculum emphasized heavy indoctrination in communism, but only incidental coverage of the physical sciences, mathematics, and languages. In later years, government leaders recognized that physics, chemistry, and mathematics are essential to national aspirations, culturally and militarily. Schools intensified requirements to the point where relatively few could manage to graduate from high school since requirements included five years of physics, biology, and foreign language, four years of chemistry, one year of astronomy, and as many as ten years of mathematics (*Soviet Commitment to Education*, 1959).

The United States has lived with the conflict between egalitarianism and excellence throughout its history, but it took on new meaning in 1918, when the Commission on Reorganization of Secondary Education issued its *Cardinal Principles of Secondary Education* (1918) which took careful note of human differences and characterized the function of the high school program as open to all young people but differentiated according to their abilities and aspirations. For some students, high school education remained preparatory to college studies, but for others it served as terminal schooling. Inasmuch as democracy is sweeping through the Western world and beyond, the American post-war history of balancing egalitarianism and excellence, and its effect on the gifted, is instructive to more and more societies in present times.

#### *The American Experience: Pre-Sputnik*

Since World War II, the greatest swings between devotion to excellence and to egalitarianism have occurred between the late nineteen-fifties and the early nineteen-seventies. Because of these changes, the five years following the launching of *Sputnik* in 1957 and the last half-decade of the 1970s may be viewed as twin peak periods of interest in gifted children. Separating the peaks was a deep valley of neglect in

which the public fixed its attention more eagerly on the low functioning, poorly motivated, and socially handicapped at school. In the late 1960s, there was a revival of earlier sensitivities to the needs of the gifted. These fluctuations in national temperament seem to indicate that the country had not succeeded in paying equal attention *simultaneously* to its most and its least successful achievers at school.

Unlocking the secrets of the atom during World War II to produce the bomb represented a scientific as well as a military breakthrough that increased the dependency of armed power on the innovativeness of the scientist. Since the bomb was produced on American soil, its citizens had grown confident that America's leadership in science and technology was unchallengeable. The nation expected itself always to be the first in creating new gadgetry to make life and death easier, be it through sophisticated home appliances, computer systems, communications equipment, or explosives with the power of megatons of TNT. It is easy to imagine, therefore, the shock when this illusion was shattered with the orbiting of *Sputnik* by none other than America's arch enemy in the midst of a Cold War that any moment could turn hotter than any conflict in history. *Sputnik* was not just a demoralizing technological feat; it had potential military applications, too. Suddenly, the prestige and survival of a nation were jeopardized because some of the enemy's greatest minds of the day had taken the lead in achievement, and the Soviets capitalized on this coup by broadcasting to every nation on earth its success in reducing America to a second-class power at long last.

As might be expected, the targets of criticism for the national humiliation were elementary and secondary schools. But it was by no means the first time that American education had been put on the defensive in those years. Four years before *Sputnik*, a sensational indictment of public education had been published (Bestor, 1953), which accused the schools of practicing what the author considered their special brand of fraudulence on America's children. The main charge was that schools were not governed by learned educators but rather by know-nothing 'educationists', a term the author used in referring to teachers, administrators, and those responsible for training them on college campuses. To his way of thinking, it was tragically ironic that 'educationists' should exert nearly total influence on the content of curricula while caring so little about the world of ideas. How could anyone presume to dictate what should be taught at school if he/she is not immersed personally in any scholarly discipline or artistic pursuit? Because of what he regarded as a misplacement of power in the hands of 'educationists', Bestor was convinced that schools provided meager intellectual nourishment or inspiration, especially for the gifted, who often marked time in their studies until graduation released them from boredom.

An even more prominent critic was Admiral Hyman Rickover, famous as the 'father' of the atomic submarine and long an advocate of programs that would identify and educate an intellectual elite for leadership in the United States. Rickover saw a deadly link between scientific advancement and military strength and warned that the Soviets were moving ahead menacingly on both fronts. Ennobling excellence was no longer just a means of improving the quality of life in a free society; it had also become a key to the survival of the free world.

Beyond the military advantages of producing knowledge and technology, there was also the matter of national prestige that Rickover saw clearly. He warned that the Soviets were in a do-or-die race with the democratic West to produce excellence in every arena that the world respected. Even the number of gold medals it accumulated at the quadrennial Olympics was counted as a badge of honour. Rickover warned that, in order to compete on an equal footing, America had to overcome its traditional guilt about singling out the gifted for special opportunities at school. Even after *Sputnik* was launched, he observed that "anti-intellectualism has long been our besetting sin. With us, hostility to superior intelligence masquerades as belief in the equality of man and puts forth the false claim that it is undemocratic to recognize and nurture superior intelligence" (Rickover, 1960, p. 30). In other words, America could not afford to indulge in a complacent sense of egalitarianism which granted compensatory education for those who needed it while denying enriched education for others who deserved it.

Since Rickover was not an educationist, his 'outsider' status prevented him from influencing school policy. However, the pre-*Sputnik* evidence that America was neglecting its gifted could hardly be ignored much longer. In a lengthy report prepared by the director of the Commission on Human Resources and Advanced Training (Wolfe, 1954), it was asserted that the United States failed to prepare enough men and women in the natural sciences, health fields, teaching, and engineering. Only six of the ten in the top five percent and only half of the top twenty-five percent of high school graduates went on to earn college diplomas. At the more advanced levels, a mere three percent of those capable of earning doctorates actually did so.

What made matters worse were expectations that the shortages would soon become even more acute in the late nineteenth-fifties unless the schools succeeded in encouraging gifted students to continue on to advanced studies. These concerns were later echoed by the chairman of the U.S. Atomic Energy Commission when he warned the nation that its public schools were not maintaining educational standards, especially for gifted students, thereby causing dangerous shortages of scientists and engineers and other technically trained individuals (*New York Times*, November 27, 1995). An

earlier *New York Times* report (May 1, 1955) estimated that, in 1954, American industry needed thirty thousand engineers but that colleges and universities had graduated only eighteen thousand. A mere two hundred physicists earned diplomas that year, and half chose not to enter the field of physics. Serious shortages existed also in industry, medicine, nursing, pharmacology, clinical psychology, and social work, among other important fields. The alarm spread to the National Education Association's Ninety-third Annual Convention in 1955. A committee report pointed out that each year two hundred thousand outstanding high school graduates did not enroll in a college before graduation. The report went on to warn that an annual loss of 400,000 highly trained men and women could force the United States to lose its superiority to the Soviet Union in the realm of technology.

And yet, pre-*Sputnik* America of the 1950s was not entirely unmindful of the nature and nurture of its gifted. In addition to conducting basic research that generated new hypotheses about intellectual functioning and preserving long-standing special school programs in a few scattered cities, behavioral scientists and educators were already demonstrating how university resources could reach out to schools and to school systems in order to further the cause of special education for the ablest. Pioneering such efforts on a nationwide scale was the Talented Youth Project under the direction of A. Harry Passow, at Teachers College, Columbia University. Initiated in 1954, three years before *Sputnik*, the project assisted school administrators and their staffs in different parts of the country to develop, implement, and evaluate their own programs for the gifted. This outreach service was in the tradition of the 1930s activities of Leta Stetter Hollingworth and her staff, also of Teachers College, who experimented with curriculum enrichment and conducted research on behalf of gifted children, albeit only in New York City's public schools rather than nationwide.

The Talented Youth Project existed for twelve years, during which time it provided technical assistance to many practitioners at their own sites and at various professional conferences concerned with the needs of the gifted. The Project staff also conducted some large-scale studies on ability grouping (Goldberg et al., 1966), underachievement (Raph et al., 1966), the comparative effectiveness of several special programs for the mathematically gifted (Goldberg et al., 1966), and the attitudes of high school students toward academic brilliance (Tannenbaum, 1962). At the outset of its service and research activities, Passow and his associates wrote a problems-and-issues monograph (Passow et al., 1955) that turned out to be not only timely for its day but surprisingly timeless, or at least as applicable nearly forty years after its publication as it was then.

### *The American Experience: Post-Sputnik*

When the American educational community finally took action on behalf of the gifted, it did so with alacrity. Enormous public and private funds became available to assist in the pursuit of excellence, primarily in the fields of science and technology. Academic course work was telescoped and stiffened to test the brainpower of the gifted. Courses that had been offered only at the college level began to find their way into special enrichment programs in high school and eventually in elementary school.

Rickover's alarms concerning Soviet advancement in technology were finally taken seriously, especially since they were expressed by a man whose own career symbolized the marriage between science and the military. His criticisms of public schools were basically motivated by concerns about national security. This coupling of education and defense became public policy through a significantly titled piece of legislation, the National Defense Education Act of 1958, which revealed a new and far more critical role for the schools than they had ever played before. While remaining obliged to produce an enlightened people capable of living together happily, responsibly, and productively in a democratic system of government, schools are also in the business of protecting its citizens from being buried ideologically, and perhaps militarily too, by a fearsome foreign power. The Act provided funds to strengthen six components of American education, one of which was the identification of gifted children. In addition, it set aside money to help schools mount programs in science, mathematics, and foreign languages, which showed where the emphasis in high-level education was to be placed.

Another influential figure in promoting excellence in American schools was James B. Conant, a renowned chemist and public servant and a president of Harvard University. In his report, titled *The American High School Today* (1959), he addressed the concerns of the post-*Sputnik* 1950s by offering a broad twenty-one step plan for changing secondary education with special emphasis on core subjects that were challenging in content and required of all students regardless of their career plans. His proposal also took special note of the academically gifted (defined as the upper fifteen percent) and the highly gifted (defined as the upper three percent), and schools took serious note of his recommendations. Perhaps the combination of the report's timeliness and Conant's personal credibility in the public schools enabled his message to get through and retain its influence for a long time, while the earlier critics' ideas, which were fairly similar to his, were taken less seriously.

In addition to the outpouring of special enrichment activities initiated in the schools during the late

nineteen-fifties and early nineteen-sixties, there was a good deal of research activity dealing with the characteristics and education of gifted children. Lewis M. Terman's studies of high-IQ children, which began in the early nineteen-twenties, had produced several landmark results that cleared the way for efforts on behalf of the gifted. One important outcome of his research was that precocious children are not mutants who possess some kinds of freakish powers bestowed upon them by biological accident. Instead, they differ from lesser abled peers in degree rather than in kind. Those who find themselves in the upper extreme of the ability continuum merely have more powerful versions of the same attributes possessed by those who are closer to average in ability.

A second enduring outcome of Terman's work was his finding that potential giftedness reveals itself even in childhood. 'Early ripe, early rot' is a once-popular platitude that he helped turn into a canard by his studies of high-IQ children growing up. Despite the many cases of aborted genius, his data provided some assurance that children with high potentialities and reasonably stable personalities stood a better-than-average chance to excel eventually in their careers, provided they were given the right opportunities at home and at school. Because of his finding that greatness does not materialize suddenly and unaccountably in adulthood, but instead has its roots in the early years of growth, professional education was convinced of its key position in helping bright children fulfill their promise. In other words, Terman confirmed the need for special educational programs for the gifted, an idea that would be irrelevant if there were no developmental connection between early promise and later fulfilment.

In claiming to reach beyond the IQ, Guilford's Presidential address at the American Psychological Association in 1950 introduced creativity as an unsung dimension of precocious development. The need to measure creativity encouraged psychometrists to abandon the assumption that tests of general intelligence, such as those developed in the early part of the century by Terman and his associates, could be used to locate the entire pool of children out of which virtually all the gifted would probably emerge. This led to a highly influential paper by Getzels and Jackson (1958) which reported a comparison of 'high-creative, low-IQ' and 'high-IQ, low-creative' students at the University of Chicago Campus High School. This study had a stunning influence on educational researchers because it announced a breakthrough in the use of so-called 'creativity' measures to identify a talent resource that was allegedly overlooked by IQ tests.

Other investigations in vogue in the immediate post-*Sputnik* period focused on the relative effectiveness of different administrative designs, such as ability grouping; enrichment in regular classes, and acceleration; the social status of the gifted at school and its effect on

their motivation to learn; the causes and treatment of scholastic underachievement among children with high potential; achievement motivation and other non-intellective factors in high-level learning; and the psychosocial correlates of divergent thinking processes. Professional journals in America were deluged with research reports and with exhortations to do something special for the gifted. So rapid was the build-up of literature in the field that one writer (French, 1959) claimed there were more articles published in the three-year period from 1956 to 1959 than in the previous thirty years.

Perhaps the most vivid recollection of the post-*Sputnik* years is that of the Great Talent Hunt. It was a time when every possible effort was exerted at federal, state, and local levels to identify gifted children and to educate them to the limits of their potential. So intense was the search for young brains, their nurture, and utilization that a parallel can be drawn between the way in which America dealt with high-level *human* resources in the 1950s and its approach to precious *natural* resources during the energy shortages of the late nineteen-seventies. Just as the nation grasped at new energy sources out of fear that it could not continue to function without them, so did the post-*Sputnik* leadership cast about frantically for signs of giftedness in the schools. And just as natural resources were dealt with in an objective, efficient manner, so did the talent hunt show signs of detachment and impersonality, as if gifted people's usefulness to society mattered more than their individualities and sensibilities as human beings.

High scholastic standards and standing, academic advancement, studiousness, and career mindedness were conspicuous themes in America's schools when the bandwagon for the gifted was rolling in reaction to the Soviet *Sputnik* threat. It became virtually unthinkable for a gifted child to bypass the more difficult courses in favor of the less demanding ones. It certainly was no time for young people to be free spirited or to enjoy the privilege of doing nothing. Instead they were brought up in a period of total talent mobilization, requiring the most able-minded to fulfill their potentials and to submit their developed abilities for service to the nation.

#### *The American Experience: The 1960s Decade of Turmoil*

The 1960s opened with John F. Kennedy's election to the Presidency amid promises and dreams of a modern utopia. There was excitement in the air as the nation prepared itself to sweep away the stodginess of the 1950s and to create a new age of excellence. Kennedy was particularly attractive to young people who saw in him (and his family) a refreshing blend of youthfulness, vitality, intelligence, idealism, and beauty. His earliest messages as President of the United States made it clear that brains and loyalty to the flag were

among the nation's most precious assets. He announced boldly his intention to put a man on the moon by 1970, a clear sign that he was accepting the Soviet challenge for supremacy in space exploration and that the most brilliant scientists would be called upon to make such a feat feasible. This meant encouraging the largest possible number of able students to enroll in science programs that offered them the best possible specialized education. For who else but the gifted could yield forth from their ranks a team of scientists qualified to honour the President's commitment?

There were other hints of meritocracy in the air. Kennedy gathered around him some of the most precocious men (though few women) of his generation to advise him on governmental matters. Known then as the 'Whiz Kids', some had earned their reputations as scholars at leading universities and others as promising ideas men in industry. All of them projected an image of braininess with a zest for unravelling the Chief Executive's knottiest problems. They were gifted children grown up and enjoying the glamor of fame and power rather than living in relative obscurity as so many other gifted people have to do even in their most productive years. At last, able children had their own celebrity role models to emulate, much as budding athletes and entertainers have theirs. The nation's leaders were demonstrating by their own example that it pays to be smart at school if you want to get ahead in life. It certainly made good economic sense because the best paying jobs were going to the best educated.

It would, of course, be naïve to suggest that America had reached a time in history when brilliant students were taking their place alongside the sports stars as heroes on campus. Far from it. Research by Coleman (1962) and Tannenbaum (1962) demonstrated that acclaim among peers was achieved far more easily on the athletic field than on the honor roll. Still, the Kennedy years were making good on promises of social and economic rewards for those willing to cultivate their superior scholastic abilities despite the lack of enthusiastic cheering from schoolmates.

The bids were high for brains in the early 1960s, but there was a string attached. President Kennedy expressed it best in his immortal admonition to his countrymen: 'Ask not what your country can do for you—ask what you can do for your country'. It was a call for unselfish accomplishment, to dedicate the work of America's citizens to the greater glory of the nation. Those with higher abilities had more to contribute and were therefore under pressure not to bury their talents or even to indulge in creative productivity that was impractical. The feeling during the Cold War was that the scientist could better serve the nation than could the poet. Judging from the career plans of gifted children in the late nineteen-fifties and early nineteen-sixties, they evidently believed that the nation was worth

serving. By far the largest number of students with high tested intelligence majored in the sciences, and many of them aspired to enter fields of technology that could somehow help the defense effort. Employment opportunities in these industries and professions were reinforced by the glamorization of science as humanity's most exciting modern frontier.

Yet the flurry of activity on behalf of the gifted left some unfinished business to haunt America ever since. Even the threat of *Sputnik* and the indulgence of excellence during the Kennedy era were not enough to guarantee that the needs of the gifted would be cared for perpetually at school. Instead, enrichment was considered a curricular ornament to be detached and discarded when the cost of upkeep became prohibitive. This is as true in the 1990s as it was in the 1960s, as evidenced by reports of cutting back on programs for the gifted as a result of budgetary crises and tax revolts in many school districts, where only programs for the handicapped learners are mandated by law to receive their usual share of special support (*New York Times*, November 29, 1992). Moreover, the fervor with which guidance counselors ushered gifted youths into sciences programs backfired to some degree as large numbers of these students changed their academic majors by the time they reached their sophomore years in college (Watley, 1968) and many who did stay on to pursue careers mapped out for them became victims of the shaky fortunes of the aerospace industry.

When the *Sputnik* scare began to wane, some special programs and curricula were retained, partly through the efforts of the newly formed advocacy groups on behalf of the gifted. But for the most part, the vast majority of educational innovations triggered by *Sputnik* and sustained in the Kennedy era proved trendy rather than long-lived despite their early promise. Perhaps the decline of interest in the gifted would have been inevitable, considering how conflicted the American public often feels about such children. Intimations of meritocracy can never fit easily into a democratic frame of reference. There will always be egalitarian-minded people who consider it necessary to withhold special opportunities that might aid the ablest to get far ahead of the pack. These critics often argue that bright children are advantaged and can fend for themselves, so why invest in them? This sentiment has circulated widely for a long time and is compatible with the popular notion of idealizing the norm, encouraging the deficient to reach as close to it as possible, and either ignoring or frowning on the efforts of the highly proficient to move far beyond it.

Nevertheless, it would be a mistake to assume that America merely grew tired of the gifted in the mid-1960s because its interest in them had been less than wholehearted all along. While attention might have declined, the fact is that there were pressures forcing the nation's preoccupation away from the gifted toward realities that seemed to be far more relevant to the

events of those days. Among the most prominent were the Civil Rights Movement, school integration and compensatory education; Vietnam and the disenchantment of youth; and growing distrust of scientific discovery.

#### *Focus on Underprivileged Minorities*

The 1954 Supreme Court decision to desegregate public schools set off an inexorable movement toward updating the Constitution and the Bill of Rights. Once again education became the linchpin of a national priority, this time for social justice, as it had formerly been for the Great Talent Hunt. Separatism and equality were declared an impossible combination and therefore unconstitutional. In 1955, Martin Luther King Jr began his leadership in the struggle for racial integration in all community institutions, including employment, housing and transportation, as well as the schools, when he led his historic boycott of buses in Montgomery, Alabama, to protest at the treatment of black passengers, an event that led to similar action throughout the country. His efforts placed the classroom in perspective as one of many battlegrounds in America's all-out campaign to raise the status of its underclasses. Educators learned quickly that pressures were mounting everywhere—not just in the schools—to take decisive action to eliminate even the subtle forms of discrimination that had hardly been noticeable over the years. It was the wave of those times and it could not be ignored.

At the top of the educational agenda, far ahead of the needs of the gifted, was the cause of low-achieving, disadvantaged children. There was a new sense of urgency to avert internal unrest by using every possible means to close the gap between the 'haves' and the 'have-nots', and it was generally acknowledged that schools would figure prominently in the process. Attention was thus shifted away from the need of the nation's talent reservoir to be kept well filled for the sake of defense and world prestige. The feeling was that somehow these problems could take care of themselves while only lightly attended to, whereas failure at school among the disadvantaged could not. In short, America was more concerned about bolstering freedom and equality within its borders than in playing the lead on the world stage, despite the unabated pressures of cold warfare that brought confrontations between East and West in Europe, Southeast Asia, and the Middle East.

In addition to diverting interest away from the gifted the advocacy movement for the socially disadvantaged actually contested at least two features of special programs for able children: (1) the use of IQ tests and other conventional measures of mental functioning as means of determining who deserves to be called gifted, and (2) grouping children in special classes for the gifted on the basis of their performance on these kinds of assessments.

Since racial minorities, such as Hispanics, Blacks, Chicanos, and Native Americans, traditionally performed less well at school than did white majorities, it was logical to suspect ability grouping for the gifted as *de facto* racial segregation. Critics argued that schools were practicing blatant favoritism by creating special classes for children who were rated superior on conventional measures of intellect and also by offering the chosen few a kind of enrichment in their curriculum that was denied everyone else. Objections were not necessarily against special ability grouping *per se* for the gifted, or even the enriched educational experience reserved for them because of their ability. What created the furor was the practice of denying enough children from disadvantaged subpopulations their rightful access to these classes. There was an overwhelming sentiment favoring the idea that high potential is distributed equitably among all races, privileged or underprivileged, but that life's circumstances in some groups are oppressive enough to cast a shadow over their innate competencies. And since nobody had ever devised a way in which to locate and nurture giftedness that was thus hidden from view, it was impossible to integrate special classes for the gifted with balanced racial quotas.

American education could not reconcile its interest in the gifted with its concern for the disadvantaged, nor could it design a satisfactory methodology for locating and cultivating giftedness among minority groups. The dilemma was easy to resolve inasmuch as it reduced itself to a choice between battling for social justice to achieve egalitarianism as against pursuing excellence, and there was no doubt as to which of the two would better fit the mood of the post-Kennedy 1960s.

#### *Vietnam and Dissenting Youth*

Although Vietnam was by no means the first confrontation between West and East, it turned out to be disastrously different, despite the fact that Kennedy's successor, Lyndon B. Johnson, justified America's entanglement on the same grounds that his predecessor defended his risks of war in Berlin and Cuba. What started out as a limited police action that was supposed to last only a short time before the expected victory would be won and American soldiers returned home, degenerated into a nightmarish entanglement with staggering sacrifices of life and no end in sight. The leadership in Washington kept the public's hopes for a quick end to the war alive by issuing deceptive reports about success on the battlefield. Eventually, the nation grew tired of war, suspicious of politicians' promises of a quick victory, and increasingly convinced that America was meddling in affairs of other nations rather than serving as a judge and enforcer of what was normally right in the world.

Among the many casualties of the Vietnam conflict was America's perception of giftedness and political leadership. The Whiz Kids of the Kennedy years, many

of whom had stayed on in the Johnson era to help formulate strategy for the war effort, eventually turned out to be *The Best and the Brightest* (Halberstam, 1972). While they were quick-minded, articulate, hard-working, and self-confident, Halberstam argued that they lacked wisdom and sensitivity to the feelings of the masses. Their cerebral artistry proved to be flashy rather than profound. They were rapidly losing their image as people who could become heroes in public life by virtue of their brainpower alone. In fact, their sad history seemed to prove that being super-smart scholastically was not a guarantee of super understanding of humanity's most serious problems and how to solve them. Gifted youths on campuses throughout the country learned to despise them for their role in the Vietnam debacle rather than revere them as graduated honors students distinguishing themselves as national leaders.

A serious by-product of Vietnam was growing unrest among students in the college. Many of them saw the war as an unprincipled adventure of the establishment in Washington and perhaps even of the senior generation (ages 30 and above) who either did not care or did not understand how their actions were affecting the conscience of idealistic young people.

Kenneth Keniston, who studied campus protestors in great detail, made it quite clear that a complex mix of personal attributes, familiar influences, peer associations, and school environments set them apart from their more conforming agemates (Keniston, 1971). However, it is noteworthy that a disproportionate number of disaffected youth on campus distinguished themselves in their studies at school and were frequently enrolled in some of the more enriched and prestigious programs. Their immediate targets were the colleges they were attending, which represented to them an establishment with archaic standards for success and unreasonable controls over their lives. Yet these same gadflies in centers of learning were themselves described in one study as possessing high degrees of intellectualism, defined as "concern with ideas—desire to realize intellectual activities—high valuation of intellectual creativities—appreciation of theory and knowledge—participation in intellectual activity (e.g. reading, studying, teaching, writing)—broad intellectual concerns" (Flacks, 1967, p. 70).

The unrest on campus underwent some dramatic changes over a relatively short time. As one observer remarked, "the key difference between the Berkeley [University] riots of 1964 and the Columbia [University] crisis of May 1968 is that in the pre-Columbian sense the major impetus for unrest stemmed from the perceived abuse or misuse of authority, whereas the later protest denied the legitimacy of authority . . ." (Bennis, 1970, p. 599). One might add that, when attention was called to the *misuse* of authority, it was an expression of protest, but when it evolved into doubts about the *legitimacy* of authority, it became a sign of

insurrection.

The revolt was not only against institutions (educational or otherwise) and their leaders; it was also against a tradition of rationalism that sanctified ivory-tower scholarship. When Columbia University rioters willfully destroyed a professor's research files, the act may have carried a message that went beyond ordinary malicious mischief and vandalism. It seemed to imply that all the work invested in accumulating those files was a waste of the professor's talent, which ought to have been dedicated to building a better society rather than to dabbling in esoterica. And to make matters worse, the educational establishment expected its brightest students to follow in the footsteps of professors like him.

Many questions were raised among gifted college students as to whether they ought to funnel their psychic energies into a life of the mind. Many were attracted to the sensitivity-training movements, which told them that "talking is usually good for intellectual understanding of personal experience, but it is often not effective for helping a person to *experience—to feel*" (Shutz, 1967, p. 11). Accordingly, the human being was increasingly seen not as a thought machine but rather as a complex biological, psychological, and social organism that can fulfill itself through all these dimensions of being. Every part of the body had to be exercised to its fullest potential, which meant building up the strength and stamina of its muscles, its sensory awareness and aesthetic appreciation, its motor control, and the gamut of its emotional and social feelings. Inhibiting other aspects of self for the sake of the intellect was regarded as amounting to robbing life of its multi-dimensionality, so the task of individuals was to make something of *all* their capacities, even if in so doing they could not make the most of *any* of them.

Significantly, a new utopia emerged in the form of Consciousness III depicted by Charles A. Reich in his then best-seller, *The Greening of America* (1971). One of the postulates of this new world was described by Reich as follows:

Consciousness III rejects the whole concept of excellence and comparative merit . . . [it] refuses to evaluate people by general standards, it refuses to classify people, or analyze them. Each person has his own individuality, not to be compared to that of anyone else. Someone may be a brilliant thinker, but he is not 'better' at thinking than anyone else; he simply possesses his own excellence. A person who thinks very poorly is still excellent in his own way. Therefore people are in no hurry to find out another person's background, schools, achievements, as a means of knowing him; they regard all of that as secondary, preferring to know him unadorned. Because there are no governing standards, no one is rejected. Everyone is entitled to pride in himself, and no one should act in a way that is servile, or feel

inferior, or allow himself to be treated as if he were inferior (p. 243).

Thus we see how life for campus dissidents becomes strangely paradoxical. Many of them espoused the habits of intellectualism generally associated with gifted students. At the same time they rejected excellence and its trappings as violations of democracy and too stultifying to the attainment of total job and liberation. Even those consenting to live the life of the mind learned an unforgettable lesson from the events in Vietnam. No longer could they be adjured to cultivate their talents for the sake of their country's prestige and need for survival. The war in Southeast Asia tarnished the nation's image enough to discourage such commitments among a large number of students who could potentially be counted among America's high-level human resources. Besides, some may have felt it faintly dehumanizing to be treated like natural resources; it simply did not fit well with the new spirit of selfhood and individuality.

### *The Devaluation of Science*

Gifted youth in the age of *Sputnik* had been bombarded with the message that a lifetime devotion to achievement in science in particular was not only in the interests of the state but of humankind in general. Such pursuits had their own built-in ethic, that any efforts at pushing back the frontiers of theory and research deserve the highest commendation because they attest to humanity's divine-like power of mastering its environment and creating its own brand of miracles. Suddenly the nation was told that science is as fallible as the one who advances it. Among the most vocal critics were the environment-minded scientists who warned that, in America's enthusiasm for conquering nature, it may be destroying its people in the process unless it imposes restraints on such activity (Bereano, 1969).

Perhaps the best known writer of the 1960s to forecast doom if science were to continue on its conventional course was the biologist, Barry Commoner, whose book, *Science and Survival* (1966), enjoyed wide circulation and influence. Commoner took the ecological point of view that the elements of nature are integrated, but human knowledge of these elements is so limited that it is not yet possible to see their connectedness. Expressing deep concern about science's preoccupation with the elegance of its methods rather than the danger of its products, he directed much of his fire at the polluting effects of such symbols of technological giantism as nuclear testing and industrial waste. He acknowledged the need for brainpower to enrich scientific thinking, but he also warned that "no scientific principle can tell us how to make the choice, which may sometimes be forced upon us by the insecticide problem, between the shade of the elm tree and the song of the robin" (p. 104). With such

caveats, it became more difficult to convince gifted children that a life dedicated to science was the kind of high calling it had once been unless closer links were made between the intellect and the conscience.

Besides being tarnished because little account was taken of their human consequences, careers in science lost more of their glitter when the job market in various related fields began to tighten. The manpower crisis dramatized by *Sputnik* gradually calmed down when America began to overtake the Soviets in the technology race and achieved a victory of sorts by transporting the first man to the moon in 1969. Previous personnel shortages in the various fields of science were no longer critical, partly because the flood of graduates in the early 1960s had filled available jobs and also because the Cold War was not considered serious enough to create new jobs through lucrative defense contracts. In fact, by the late 1960s, many Americans were suspicious of the so-called 'military-industrial complex' for carving too much out of the tax dollar to support projects that they considered wasteful in times of peace. The primary need, as seen then, was to solve the problem of social unrest rather than to prop up defense technology. Many would-be scientists and engineers began to realize that these professions attracted neither the prestige nor the occupational rewards that would have been guaranteed only a few years earlier. However, the supply of scientific talent did not slow down in accordance with the reduced demand, and as a result of the imbalance, many highly trained personnel found themselves either unemployed or working at jobs outside their fields.

### *The American Experience: Renewed Interest in the Gifted in the 1970s*

The decline of attention to the gifted in the 1960s is evident in the contrasting volume of professional publications on that subject at the beginning and end of the decade. The number of entries under 'Gifted children' in the 1970s volume of *The Education Index* was less than half the number in the 1960 volume. Nevertheless, by the outset of the 1970s, there were unmistakable signs of a revival of interest.

Probably the biggest boost came from a 1970 Congressional mandate that added 'Provisions Related to Gifted and Talented Children' to the Elementary and Secondary Educational Amendments of 1979. This document expressed a legislative decision to include gifted students among those receiving help from the Elementary and Secondary Educational Act and the Teacher Fellowship Provisions of the Higher Education Act of 1956. It also directed the Commissioner to: (1) determine the extent to which special education assistance programs are necessary or useful to meet the needs of gifted children; (2) show which federal assistance programs are being used to meet the needs of gifted children; (3) evaluate how existing federal educational assistance programs could be used more

effectively to meet these needs; and (4) recommend new programs, if any, required to meet these needs. The target population was defined as the upper three to five percent of school-age children with outstanding promise in six categories of giftedness: general intellectual ability, specific academic aptitude, creative or productive thinking, leadership ability, visual and performing arts, and psychomotor ability.

In response to the mandate, the then-commissioner Sidney P. Marland, Jr issued a report of his findings and recommendations that set the stage for doing something significant about the deteriorated condition of programs for the gifted (Marland, 1961). He estimated that only a small percentage of the 1.5 to 2.5 million gifted school children were benefitting from special educational services and that such services had a low priority at virtually all levels of school administration. Furthermore, even in those localities where there were legal or administrative directives to provide special offerings, little was accomplished due to other funding priorities, more threatening crises, and the absence of adequately trained personnel. Clearly, Marland saw the gifted as a deprived group whose talents were in danger of serious impairment unless appropriate intervention strategies were planned. He therefore declared his intention to initiate a series of major activities at the federal level with the hope of inspiring and pressing for more commitment on behalf of the gifted throughout the nation's schools.

As a result of federal encouragement and some public and private initiatives, the gifted were exposed to an increasing number of special educational experiences in the 1970s. While as late as 1973 fewer than four percent of the nation's gifted were receiving satisfactory attention at school, and most of the fortunate ones were concentrated in ten states, the nationwide picture improved considerably within the decade. Zettel (1979) reports the following outcomes of a survey conducted in 1977:

- (1) nearly 75% of the states already had statutory definitions of gifted children;
- (2) thirty-three (or 66%) of the states reported an aggregate increase of nearly 25% over the previous year in the number of gifted children served;
- (3) thirty-one (or 62%) of the states increased their appropriations for the gifted by 50%;
- (4) forty-two states reported sponsoring some kind of in-service training for persons interested in serving the gifted, a 110% increase over the previous year.

There was talk about possible legislation that would change the Federal Bureau of the Handicapped to the Bureau of Exceptional Persons, thus including gifted individuals as eligible for sustained support of their education, along with the handicapped. If this kind of move had been made, it would have gone a long way toward erasing the image of gifted education as being only a periodic fad in the schools. It was admittedly a

way of forcing attention on the ablest by tying their fortunes to those of the handicapped, for whom funding has rarely abated appreciably. The change in name never came to pass, possibly because the American public could never feel equally sympathetic to the needs of children at both ends of the ability continuum.

Despite the fact that the definition of giftedness had been broadened by the Marland report, little more than lip service was given to children who showed precocity in domains other than academics. Even less fortunate were the gifted among the underprivileged minority populations who remained largely neglected, except in the arts and sports, but not deliberately so. There is no doubt that many educators would gladly have initiated enrichment experiences for these children and that support was obtainable for such plans if they had stood a chance of success. However, the profession was stymied in its efforts to find a clear way of discerning high-level academic potential that was buried under a thick overlay of social and economic handicaps. In fact, it is hardly less difficult today than it was then to inspire the fulfillment of scholarly talent in the nation's underclasses.

In its desire to sustain interest in the gifted, the federal government funded projects designed to strengthen leadership in the field and to spread advocacy at the grass-roots level. The National/State Leadership Training Institute received federal funds to help state education departments develop viable plans for educating the gifted. In addition, Teachers College, Columbia University, was provided with support to coordinate efforts by seven universities in recruiting and training graduate students to become seminar figures in the field. It was seen as a long-range investment in the careers of men and women who had shown promise for making significant contributions in the 1980s and beyond. Besides these nationwide projects, the federal government, along with state, city, and private agencies, sponsored many regional and local programs for the gifted. The emphasis was mainly on enrichment practices, whereas research and experimentation received relatively little encouragement.

A review of the state of research for the years 1969 to 1974 reveals a fairly bleak picture (Spaulding, undated). These efforts continued to be limited throughout the 1970s, but there are several major exceptions worth noting. They include the 1971 initiation of Julian Stanley's (1976) continual studies of mathematical precocity, Halbert Robinson's (1979) investigations of the cognitive development of young able children, and Pauline Snedden Sears' (1979) and Robert Sears' (1977) assessment of the Terman population in their senior period of life.

What prompted the resurgence of activity in the education for gifted children after nearly a decade of quiescence? A full answer will probably never be known, but the explanation that seems most obvious is

America's backlash against what it saw as a youth turned excessively self-indulgent, indifferent to scholastic achievement, and hostile towards some sacred, scholarly traditions. Wagner (1976) published a scathing indictment of universities for compromising academic standards, inflating grades, and diluting degree requirements to fend off unrest among students. His sentiments, shared by many other educators at the time, were signs that the pendulum had swung away from extreme egalitarianism in the direction of excellence. It is hard to image the youth of the late 1970s accepting the Consciousness III notion that brilliant minds are not better at thinking than anyone else. However, the revival of interest was no more a sign of pure historical inevitability than was its decline a decade earlier. What accounted for the revival, at least in part, was evidence of initiatives taken by people who believed in differentiated education at every ability level and who participated in vigorous campaigns to save the schools.

#### *Prescriptive Teaching for All Children*

When Riessman published his highly influential book on the culturally deprived child in 1962, he reiterated a number of criticisms of the schools made some fifteen years earlier by Davis and Havighurst (1947). The charges were that the curriculum was excessively loaded with verbal content and therefore placed underprivileged children at a disadvantage; that the subject matter was irrelevant to the vital concerns of these children; that teachers espoused values and behavior codes that were oriented too narrowly toward middle-class living; and that schools were so preoccupied with teaching the disadvantaged how to become socially mobile that they were in effect trying to create a melting pot rather than striving to strengthen cultural pluralism. However, researchers did not take their lead from such charges. Instead of tampering with the old curriculum, they tried to create a learning environment that would enable the disadvantaged to meet the more conventional demands at school.

Among the most notable experiments that sustained their influence at the time were those conducted a decade earlier by Martin Deutsch (1964) and his associates. They attempted to forestall educational retardation by intervening early in children's lives and equipping them with the readiness skills that they could not derive from their social milieu. This required developing elaborate ways in which to diagnose individual learning profiles and to match instructional treatments to them. It paralleled developments in special education for the handicapped, which emphasized prescriptive teaching based on increasingly sophisticated methods of diagnosing intellectual processes. This orientation led to nationally mandated requirements that every handicapped child have an individual diagnosis, prescription, and evaluation.

Attention to specific competencies among the handicapped dramatized the need for individualized education, with *all* children receiving a fair share of what is uniquely appropriate for them, regardless of how deficient or proficient they are in mastering curriculum content. Advocates for the gifted argued that these children should also receive special attention to accommodate their unique learning strengths and thereby demonstrate the educator's attention to human differences. These protagonists pointed out that the more sophisticated educators become in discerning human individuality, and the more inventive they are in providing for individual needs of the ablest, the more likely that America could achieve equality at school.

#### *The Role of the Gifted in 'Rescuing' Public Education*

It is no secret that educators in the 1970s searched desperately for ways in which to maintain order in thousands of classrooms. This was especially true in big-city schools where ten percent of the nation's pupil population was enrolled. The dismal picture was a familiar one: scholastic achievement levels were three, four, and even five years below norms; drugs, violence, vandalism, and truancy reached epidemic proportions; and costs climbed to such a height that there was always the danger of insufficient funds to pay the bills while maintaining an adequately staffed program. Many middle-class families fled the inner city in the 1970s or sought help from private schools in order to provide a meaningful educational experience for their children. This further aggravated the situation in urban centers.

School administrators became aware that one way in which to bring back the middle classes to inner-city schools was to initiate special programs for the gifted. They therefore opened so-called 'magnet schools' that offered enrichment activities in particular subject matter areas to attract sizeable numbers of children who would otherwise have been studying elsewhere. The presence of the ablest began to make a difference in the total school atmosphere, which demonstrated that these children were capable of enhancing all education if their learning capacities were properly respected. Again, special education for the gifted was initiated for the sake of solving social problems rather than solely for the sake of those who need, or could benefit from, it.

#### *The American Experience: Peaks and Valleys in the 1980s*

At the conclusion of his personal retrospective on three decades of education for the gifted in the United States, Passow (1980) wrote: "I was once again struck by the cyclical nature of our interest in and efforts on behalf of the gifted and talented" (p. xvi). Perhaps the most positive statement that can be made about the gifted in the 1980s is that they prevented George Orwell's 'Big Brother' era from arriving in 1984 as he had predicted.

In fact, if Orwellian forecasts ever come true, it will be tragic proof of how ineffectual educators have been in nurturing talent for the strengthening of selfhood in the human family. But even the failure of 'Big Brother' to materialize is no guarantee that America will succeed in finally breaking its vacillation between public enthusiasm and apathy toward gifted children in the foreseeable future. All that can be said about the 1980s is that there were both positive and negative developments in the school and society, and that it is too early to tell what the eventual effects of these developments will be.

#### *New Sources of Talent*

It was already apparent that women and low-status minorities were moving toward parity with middle-class white males in the extent and variety of their advanced education. Trends have indicated a sharply rising representation of women in every creative field over the ten-year span from 1975 to 1985, when there was only a 6% increase in first professional degrees for men, as compared to a huge 122% increase for women. During the same period, the number of earned doctorates among men inched up from slightly under 27,000 to about 28,000, or 4%, whereas for women the jump was from some 8000 to about 14,000, or about 75%.

Considering the changing status of women in society, it is difficult to imagine that talent among them will continue to be suppressed as in former generations. Parents of school-age girls do not tolerate such biases as readily as the girls' grandparents might have, especially if the mothers of these children are themselves members of the new generation of women with advanced training and are in mid-career. Furthermore, opportunities for employment at higher skill levels have increased dramatically for women in recent years, and will continue to do so in the foreseeable future. According to the U.S. Bureau of Labor Statistics, the number of men added to the labor force from 1979 to 1985 was 8.1 million, not even half the 16.5 million figure for women. By 1995, more than 60 of every 100 women of working age will be employed, an increase from 43 per 100 in 1970. They will then constitute over 45% of the prime-age work force. Some of the professional occupations filled mostly by males possessing marketable talents that require advanced training are now absorbing unprecedented numbers of women. These professions include engineering, law, medicine, dentistry, and the life sciences.

The educational and occupational opportunities for bright African-Americans has also improved over the past half century. In 1940, total black enrolment in post-secondary education was less than 50,000, and over 95% of that group was enrolled in traditionally Negro Colleges (Pifer, 1978). By 1976, the number of blacks in colleges and universities had risen dramatically to 1,062,000 and for the 1975–1976 academic

year alone, more than 83,000 blacks earned baccalaureate, masters, medical, law, and PhD or EdD degrees (Pifer, 1978; National Center for Education Statistics, 1978).

There is reason to expect the upward trend to continue as more and more people from minority groups are accepted into the managerial, professional, and technical segments of the labor force. What women, blacks, and other minorities have found in the high-skill labor market in the late 1980s is an increase of about 29% over the mid-1970s in the number of professional, technical, and kindred occupations. What they also discovered, unfortunately, is that the total number of adults with advanced education increased more sharply, thus dimming the employment outlook for them. The openings for PhDs over the 1972–1985 period for growth and replacement was about 187,000, whereas the actual supply of new PhDs numbered as many as 580,000 in the second half of the 1980s. It stands to reason, therefore, that doctoral recipients from all subpopulations have found it difficult to locate work commensurate with their training. But the women and other minorities are most vulnerable on account of age-old prejudices that bar them from many positions of prestige.

#### *New Trends in Diagnosing and Nurturing Excellence*

Traditional tactics for identifying gifted who might qualify for the talent pool are under pressure to undergo change, some of it radical. There is no end in sight to the debate over the meaning of IQ, its measurement, and the nature-nurture issues that revolve about it, all of which arouse powerful emotions as well as scientific interest. In the 1970s, some behavioral scientists (Estes, 1976; Voss, 1976) foresaw a decline in the concept of intelligence as a useful description of higher-level cognitive powers. They expected it to be replaced by more diagnostic analyses of the patterns and processes of human functioning. This kind of orientation to the measurement of intellect conforms to the pioneering approach taken by Piaget (1952) in monitoring clinical development of children's problem-solving behavior.

Despite the criticisms of IQ for identifying gifted children, there has never been a complete let-up in such practice. In a recent review of all empirical studies published in the *Gifted Child Quarterly* over two years (1990 and 1991), Tannenbaum (1992) discovered that in the 22 published reports of research on the gifted, all of them listed IQ, or alternative tests that correlate highly with IQ, as the measure of choice for identifying experimental samples. This is not surprising in light of previous findings by Snyderman and Rothman (1988) which shows that psychologists and educators knowledgeable in areas related to intelligence testing generally agreed that IQ instruments are valid and useful in measuring some of the most vital aspects of intelligence. Obviously, test users have been paying

little attention to the advice and efforts of academic psychologists to promote new ways of assessing high potential in children.

Among the changes strongly advised by theoreticians has been to examine specialized talents that demonstrate extraordinary rates of mastery and of creativity. Gardner's (1983) list of such aptitudes has been widely circulated, and includes linguistic, logical-mathematical, spatial, bodily-kinaesthetic, musical, interpersonal, and intrapersonal intelligences.

Another major trend in describing high potential in children is through the study of mental processes, exemplified by Sternberg's (1986) 'Triarchic Theory', so named because it contains three sub-theories. One of them is 'componential', and it consists of three kinds of components involved in the performance of separate mental operations: (1) metacomponents, or the executive processes needed for planning, monitoring, and decision-making in a problem-solving situation; (2) performance components, which include processes needed for executing a task; (3) knowledge acquisition components used in the selective encoding, selective combination, and selective comparison operations. Another sub-theory is called 'experiential', which incorporates the ability to deal with novelty and the ability to automatize or habituate information processing. The third sub-theory is called 'contextual', which refers to the organism's selecting, shaping, and adapting to its real-world environment.

Ramos-Ford and Gardner (1991) have experimented with ways of departing from the usual pencil-and-paper tests of ability to monitoring children carefully and systematically for their performance in learning environments that bear some resemblance to real working conditions. It remains to be seen whether such an approach can improve upon conventional testing methods, which critics consider antiquated and inefficient.

A sharply different testing method has been developed by Feuerstein (1979), who also opts for measuring the dynamics of human potential. This means determining the extent to which children's functioning levels can be modified through what he calls mediation, or the examiner's use of appropriate helping tactics and practice materials. The idea of mediating the child's entering behavior in a test situation is novel in that it revises the role of the examiner from that of an objective observer to a participant observer who orients the child to the underlying cognitive principles involved in the test experience. Feuerstein asserts that the organism is so modifiable that mediated learning affects not only the cognitive functioning of the individual but the structure of intellect as well. Such is the power of regulated encounters between the individual and environment.

### *Programs and Provisions*

In 1954, Tannenbaum conducted an informal survey of American schools singled out in a 1941 published

report as offering exemplary enrichment programs for gifted children. The purpose of the communication was to find out what had happened to those programs over the intervening 13 years and how schools in 1954 could benefit from the experiences, including the successes and failures, of the 1941 programs. Of the 100 schools contacted, nearly all replied, and in every case the original programs were no longer in operation. In fact, they were never meant to last a long time. What they had amounted to were imaginative projects initiated by talented teachers and supported by administrators who shared their concern about the plight of the gifted.

The survey revealed a fundamental difference between *programs* and *provisions* for the gifted. A program can be defined as a comprehensive offering, sequenced over a long period of time, usually designed as a requirement, and very much a major part of the total school curriculum. Thus, the school offers programs in mathematics, literature, art, social studies, and the like. A provision, on the other hand, is more fragmentary, an *ad hoc* offering, relatively brief in duration, often designed by an individual teacher with special abilities rather than by a curriculum committee, and supplemental to the major offerings, not integral with them. What the 1954 survey revealed is that the 1941 schools had offered provisions rather than programs. Indeed, wherever enrichment of any kind has been initiated into the school curriculum, in most cases it has amounted to add-on provisions that sooner or later disappeared because of lack of strong enough commitment or sufficient funds to retain what was generally seen as a curriculum luxury rather than necessity. In fact, the lesson learned in the 1954 study was confirmed more than 30 years later. The Richardson sponsored investigation (Cox et al., 1985) reports a survey of some 16,000 schools (of which only about 10% responded, an ominous sign in itself) that found once again only fragmentary enrichment provisions, not programs, in most schools that claimed to be servicing the needs of the gifted.

Despite schools' reluctance to invest in long-range programmatic development for the gifted, there were some encouraging signs in the 1980s that conceptual frameworks for curriculum development could at least be available to those interested in them. School officials were offered program paradigms that they could adapt or adopt for actual implementation. In Renzulli's (1986) *Systems and Models for Developing Programs for the Gifted and Talented* no fewer than fifteen such designs are described in detail by their creators. They are by no means the only ones available for implementation. Not included, for example, is the work of Stanley and the Johns Hopkins Study of Mathematically Precocious Youth (SMPY). Initiated in 1971, SMPY has spread to nearly every corner of the United States, with more and more school systems subscribing to Stanley's ideas about fast-paced instruction for junior high school-age children who are

advanced in mathematics. By now, large numbers of young adolescents throughout America, and recently in Germany as well, are being tested in hopes of being placed in any of a number of enrichment settings, such as afternoon and summer classes as well as college courses that offer advanced study. If SMPY and other enrichment paradigms are adopted increasingly in the United States and in other Western countries, it will signal a movement away from *ad hoc* provisions to much longer range programs for the gifted.

Unquestionably, the largest-scale effort on behalf of the gifted in the last decade of the twentieth-century and possibly of all time, is the federally funded project conducted by the National Research Center on the Gifted and Talented. Initiated by Joseph S. Renzulli at the University of Connecticut, it involves three additional universities in joint leadership for the development of theory, research, and programs across the United States. More than 200 elementary and secondary schools throughout the country collaborate as experimental sites, and as many as eleven major so-called 'stakeholders' are targeted for dissemination and impact. 'Stakeholders' include lay and professional organizations, business, industry and labor, legislative bodies, and the media, among others.

In its own summary of objectives (Renzulli, Reid and Gubbins, undated), the Center is committed to designing and carrying out 'theory-driven quantitative and qualitative research that is problem-based, practice-relevant, and consumer-oriented' (p. 3). It has thus dedicated itself to providing intellectual leadership that will hopefully ensure continued public attention to the needs of the gifted for years to come into the twenty-first century.

It is much too early to assess the Center's realization of its lofty hopes. But it bears monitoring closely as a model that may deserve preservation and replication in Western countries because of its sheer scope, size, ambition, and organization, should it prove successful in the long run.

### Final Thoughts About Present and Future Trends

Current prospects for recognizing the special needs of gifted children worldwide are still subject to the excellence-egalitarianism dilemma which Fetterman (1988) regards as universal. At the conclusion of his international survey of enrichment offerings for the gifted, Brickman (1979) observes: "the dogma that democracy is at the opposite pole from meritocracy based on individual talent, skill, aptitude, ambition, and ability is at least open to serious difference of opinion... A democratic society can pursue an egalitarian policy if it provides the fullest possible education for each person without regard to background and status, social, economic, political, religious, racial, sexual, physical, and mental. Under such a policy, all individuals will receive their demo-

cratic due, including those who are gifted and talented' (p. 329).

Indeed, there are some signs that Brickman's optimism may be justified. The membership in the World Council on Gifted Children consists mainly of professionals and lay advocates from democratic nations, and its biennial meetings have drawn large numbers of participants from these and other countries. Similar lively participation is shown at conferences sponsored by national and local associations on behalf of the gifted in the United States. Educationally, European democracies have tended to maintain their traditional school structures which differentiates education for university-bound students. These countries have also exposed at least some of their precocious children to various kinds of enrichment experiences in and out of school. Some of this activity is especially noteworthy, as more and more Western and Western oriented democracies are making highly promising contributions to the field. For example, Heller's fifteen-year longitudinal study of the gifted in Germany (Heller, 1991/1996; 1992, 2000; Perleth & Heller, 1994; Perleth, 2000) is designed to clarify identification criteria that may be used in all special programs; Israel's Ministry of Education is sponsoring many adventurous enrichment experiences for the gifted at the elementary and secondary levels, and the newly established Israel Academy for the Sciences and Arts has initiated an extraordinarily imaginative program for the gifted that is attracting worldwide interest; the SMPY program for the mathematically gifted is spreading throughout the United States and beyond; and the enrichment curricula designed by a permanent committee of expert educators in Singapore has been operating with notable success in recent years.

Yet, ambivalent feelings toward the gifted persist even to this day. Aside from fears of elitism in a democracy, there are suspicions that only a thin line separates genius, or even giftedness, from insanity. Some argue that in the interest of cosmic fair play, nature somehow balances off mental superiority with emotional or physical handicap. Others are suspicious of the creative as potential iconoclasts who make life uncomfortable; they find it easier to live with the familiar than to be prodded into the unknown by unconventional ideas, be they political, social, artistic, literary, or scientific. Still another, more recent, tradition is the belief that super-rational powers, which are so popularly associated with so many kinds of giftedness, are not all that critical in affecting the human condition, either because irrational impulses also figure greatly in individual accomplishment (according to Freud), or because no amount of effort by any one person, however brilliant he/she may be, can cause more than a ripple in the inexorable tides of history (according to Marx).

Opponents of differentiated education for the gifted surface time and again in professional journals and

forums. They believe that talent is irrepressible in some children and impossible to nurture in others. Why, then, invest in special programs for the gifted? Sometimes the question is raised cynically by those opposed to any kinds of special programs, except for the handicapped. Many more objectors are skeptical rather than cynical about the need for providing 'extras' to children who can allegedly excel without them. In the past, these periodic criticisms have placed advocacy for the gifted on the defensive despite anything anybody could say on its behalf.

### *The Changing Status of Gifted Achievement*

Usually, an account of history of/and giftedness in Western society deals with outstanding individuals and their nurturance. There is rarely any doubt that gifted performance or production matters in the sense that it attracts critical admiration, even acclaim, temporarily or for all time. This seems to be changing. It is now necessary to take into account the prospects of noteworthy achievement per se by asking whether indeed it has a future.

Examples that come to mind include the classical symphony orchestra and its repertoire as well as the literary novel that is written by an author and bound in the usual print form. Of the symphony orchestra, the Arts and Leisure section of the *New York Times* (January 31, 1988) offers the following speculation:

The date is January 31, 2038. At eight o'clock tonight, Carnegie Hall will be the scene of a special concert of rediscovered music—music that has not been played for three decades. There will, however, be no orchestra—not enough people play the violin, or the cello, or the oboe, anymore. All of the instruments will be played on a new computer, programmed for the occasion: the Bach 9000, which sounds more like an old-fashioned symphony orchestra than the real thing. For the last thirty years, Carnegie has specialized in Pop, Rock and Rage, the new fusion of New Age and Rock, but not tonight. The rediscovered works: Symphony #9 by Ludwig van Beethoven, Eine Kleine Nachtmusik by Wolfgang Amadeus Mozart, and Brandenburg Concerto #2 by Johann Sebastian Bach.

Such a scenario depicts a total break with the past rather than a creative accretion to it. Vivaldi and Schnittke do not survive in the company of their successors. Instead, the masterpieces of previous generations are banished to the archives, to be revived only on rare nostalgic occasions. Never before have artists and their art been declared obsolete, irrelevant, and unwelcome with such finality, as projected so seriously in the *New York Times* feature essay.

Should these speculations come true, they will constitute a major threat to the very concept of excellence as it is now known and accepted. No matter what differences exist in the way people define and

evaluate giftedness, creativity, and genius, all agree that a high quality of human productivity or performance is a *sine qua non*. Some individuals who are celebrated for their work, even for many years, may eventually fall into disrepute. But at least the legacies of some *do* survive to maintain society's cultural treasures. By nullifying *all* of them at once, or even in time, raises doubts as to whether quality per se can survive as an essential ingredient of excellence. Surely *some* artists and their artistry contain enough brilliance to ensure their immortality. If they don't endure, then the criterion of quality has been replaced by something else. By what? Is it possible that mediocrity will some day be extolled for no other reason than its being new and different? How will music be critiqued, if not by its aesthetic value, however that is judged? Could Western society be entering an era when the beauty of musical statements counts for nothing, and all that matters is the arousal of people's deep impulses by *any* pounding, persistent beat with accompanying sound, however pedestrian it may be, even if it is programmed for 'performance' electronically rather than *interpreted* by an instrumental artist? If so, giftedness in music will take on a radically new meaning, if indeed it retains any real meaning at all.

With respect to the future of literature, the novelist, Robert Coover (*New York Times*, June 21, 1992) states:

In the real world nowadays, that is to say, in the world of video transmissions, cellular phones, fax machines, computer networks, and in particular, out in the humming digitalized precinct of avant-garde computer hackers, cyber punks and hyperspace freaks, you will often hear it said that the print medium is a doomed and outdated technology, a mere curiosity of bygone days destined soon to be consigned forever to those dusty unattended museums we now call libraries. Indeed, the very proliferation of books and other print-based media, so prevalent in this forest-harvesting, paper-wasting age, is held to be a sign of its feverish moribundity, the last futile gasp of a once vital form before it finally passes away forever, dead as God.

Coover observes that the novel "is perceived by its would-be executioners as the virulent carrier of the patriarchal, colonial, canonical, proprietary, hierarchical and authoritarian values of a past that is no longer with us." In the novel, as it is traditionally constructed, the author is alleged to wield dictatorial power, not only over plot and character, but also over the format through which they are presented: on lines to be read from left to right (right to left in some languages), in sentences, paragraphs, pages and chapters. Freedom from this kind of literary tyranny is supposed to come from the so-called 'hypertext', in which the linear-sequential structure is eliminated with the help of computer programming. Unlike print text, hypertext

liberates readers from control by the novelist and, instead, allows them to become partners in the creative enterprise by involving them in the process of mapping and remapping textual content, "not all of which is provided by what used to be called the author" (in Coover's words).

As the novelist is relieved of the burden of unilateral creation, he/she is no longer the shaper of a complete narration, but instead becomes a collaborative arranger of text, together with erstwhile consumers of text. This is done by providing readers only with sketches of fictional events in no particular sequence and allowing them to fill in details independently in any way they choose to form webs of connection among the sketches. In other words, talent in writing novels becomes democratized, as everybody enjoys the right to participate in the process of producing plot and character on an equal footing with the gifted novelist. By thus being stripped of the task of composing stories in full detail from beginning to end *alone*, creatives in this domain lose their distinction and even their visibility as potential contributors to quality literature.

The mere speculation about such changes raises questions concerning gifted children with promising careers on the concert stage and superb young writers of narrative who may have the next great novel stored in their imaginations.

In another vein, consider Flynn's (1987) large-scale study of intergenerational gains in IQ in countries where such data were available. He found that present-generation 20-year-olds in Holland score about twenty points higher in IQ than did their counterparts some 30 years earlier. Both groups were compared on the same test using the same norms. An increase of such dramatic magnitude means that, in his sample at least, the number of persons with IQs of 150 and above has increased proportionately by a factor of almost 60 from the previous to the following generation. Yet, the number of patents granted has actually diminished, with the 1980s showing only sixty to sixty-five percent of the yearly rate for the 1960s. This may mean that IQ is no longer as relevant to the world of invention as it once was, or more probably, as scientific knowledge accumulates and inventions become more and more sophisticated, the threshold IQ has to rise in order to qualify a child as a potential producer of scientific ideas.

The Flynn (1987) results may be symptomatic of a trend toward fewer and fewer people capable of mastering more and more sophisticated knowledge, much of it sheltered from more popular consumption by convoluted neologisms. University professors in the 1960s were attacked by student activists who felt their would-be mentors were, in-effect, 'fiddling while Rome burned'. The students felt that the professors were elitist snobs, so tunnel-visioned that their own theories allowed no room for alternatives. Such criticisms may have led to the Consciousness III

declarations of exasperation and Reich's (1971) rejecting the concept of excellence and comparative merit.

The Reich suggestion that everybody is brilliant implies that brilliance has no distinctive meaning. It democratizes abilities and thus leads to the conviction that all products of the mind are created equal, free of criticism or comparative evaluation. This stance is entirely compatible with that of Paul de Man, the Belgian scholar who was instrumental in spreading the theory of deconstructionism in the liberal and fine arts. Supporters of the theory regard it as a reexamination of the humanist legacy, but opponents see it as an attack against the traditional canon.

According to deconstructionism, language in literature, art, and music, never means what it appears to mean. It discards the evaluational aspects of these creative products by declaring them neither good nor bad. Also discarded are attempts to analyze the ideas of writers, artists, and composers. What counts instead is the emotion that literature, art, and music generates in the reader, viewer, and listener, regardless of whether these feelings are embedded in the creative products *per se* or in any way intended by the creators of these products.

The reactions to masterpieces are so personal and so differentiated according to who is reacting that the objects of these responses need not be masterpieces at all; anybody's work can qualify as a stimulator, which makes anybody as important a creator as everybody else. Sometimes the responses embody deeply felt political or social convictions, or even sexual meanings (McClary, 1987).

Aside from the philosophical consideration of deconstructionism, if the excellence of a creative product counts for nothing because there is no concern for standards or criticism or appreciation, what is the meaning of precocity and its cultivation? How can educators differentiate curriculums for the gifted when there are no human differences acknowledged in a society where *all* children are considered gifted, or not gifted? Can there be patronage of the arts which have no intrinsic value except as objects of highly personal projections? In other words, is the world of ideas witnessing the end of history of the gifted?

Similar questions may be raised in relation to a growing distortion of multicultural education. Traditionally, multiculturalism has advocated the incorporation of great ideas of all cultures and subcultures in the curriculum. It has also fostered the appreciation of the different histories, languages, lifestyles, and values of foreigners as a means of combating xenophobia and racism. However, these highly constructive and much needed additions to school curricula are occasionally ignored in favor of a radically different version of multiculturalism, exemplified in the Stanford University students' chant, "hey, hey, hey—ho, ho, ho, Western Civilization's got to go." 'Western Civilization', in this case, refers to the

required course of reading great Western literature written by authors caricatured as dead white European males (DWEMs). Some of these great works, which have been treasured for centuries in Western society, had to be discarded from the requirements list and replaced by works selected primarily on the basis of their representing minority subcultures and achieving more of a balance of representativeness among the races and sexes.

Again, excellence is democratized by removing quality as the sole criterion for judging it and substituting in its stead an adherence to subcultural representation for its own sake. The gifted can continue making history and being part of history only if their products and performances are judged strictly by their worthiness, not as commonplace instruments for flushing out other people's emotions or *only* because they emanate from a minority group that seeks and deserves its place in the sun. It remains to be seen how long the element of quality in giftedness, talent, precocity, and genius will remain under attack in the years to come. The stakes are higher than ever in the world of the gifted, and indeed in the world at large.

### **The Study of Giftedness at the Beginning of the Twenty-First Century**

Long before the first Christian millennium, the gifted were already subjects of special public attention. Indeed, people probably became interested in giftedness from the time they first recognized ability differences in each other and in their children. Then as now, general attitudes toward differentiating education for the ablest probably ranged from approval to apathy to ambivalence to antagonism. This lack of consensus is not about to change at the turn of a new century. Advocates for the gifted have enough commitment and influence on policy makers to keep many special enrichment services ongoing in the foreseeable future, while those who protest such services also enjoy sufficient influence to dampen full-scale support for the needs of highly creative and accelerated achievers at school. What lies ahead, then, is likely to be much more than minimal, and much less than maximal, opportunity for the most precocious schoolchildren to be challenged in full measure, educationally. 'Aye'-sayers to the desirability of exposing every qualified student to expanded and accelerated curricula, together with their 'nay'-saying opponents to such measures, constitute a small minority of those capable of influencing school policy. The vast majority either doesn't care or is conflicted about the issue, and will probably remain that way for years to come.

Relatively few school administrators take the initiative in mounting programs for the gifted. Instead of being pro-active, they tend to be reactive in response to bright students' parents who plead and pressure for more challenging educational fare to relieve their children's boredom in lock-step programs. Whatever

enrichment is then introduced tends to be provisional—easily discarded when school budgets are reduced or when the beneficiaries of temporary add-on learning exercises graduate, especially if there are no parent-advocates to clamor for the rights of a new wave of precocious students. Wherever special education for the gifted is treated as a curriculum elective rather than a requisite, a luxury instead of a necessity, the unique needs of most of these children will remain at the edge of school life, sometimes struggling to get in and sometimes in danger of falling out. The 'Aye'- and 'Nay'-sayers are locked in a seemingly endless struggle to capture the allegiance of the much greater numbers of educators whose attitudes are divided between indifference and indecisiveness. Both extremes alternate in winning battles, but neither has ever won the war decisively, and perhaps never will. At this historic change in eras, only the euphoric would dare anticipate universal special education for all children deemed gifted, by any means of identification. Some vital realities in school and society stubbornly resist change, and the treatment of unequals remains largely undifferentiated, except for handicapped learners.

### *Expansion of Advocacy and Service*

Although widespread malaise in servicing the special needs of the gifted in public education still prevails at the turn of a new century and millennium, increasing numbers of professionals and lay people are active on behalf of this population, and the participation in these activities promises to grow in the course of time. Some two thousand educators and psychologists usually participate in the biennial conferences of the *World Council for the Gifted and Talented* (WCGT). Nearly that many attend the annual meetings of the *National Association for Gifted Children* (NAGC), a country-wide organization in the United States. In early December, 1999, the twenty-second annual conference of the *Texas Association for the Gifted and Talented* attracted more than 6,000 parents, teachers, psychologists, and school administrators to two days' attendance at some 400 seminars and several keynote addresses.

In other regions of the world, the *European Council for High Ability* (ECHA) and *Australia's Gifted Education Research, Resource and Information Centre* (GERRIC) bring together leading students and educators of the gifted periodically to share ideas with large numbers of their respective constituent colleagues. In addition to the efforts of worldwide, regional, and local advocacy organizations, many universities are providing sustained and intensive training to selected children, their parents, pre- and in-service teachers, supervisors, school administrators, and support personnel. In some instances, college faculty members teach qualified school-age children advanced topics in selected disciplines. Other courses may not necessarily

be advanced, but are outside the scope of the regular school curriculum and fit into the range of a few children's interests as well as the instructors' areas of expertise.

Inasmuch as support services for precocious children already exist at many college campuses (too many to list here), it would be revealing to note some of the largest-scale efforts that promise to figure prominently in the years ahead. Thus far, the most duplicated, replicated and extensively researched program, based originally at Johns-Hopkins University, is Julian C. Stanley's *Study of Mathematically Precocious Youth* (SMPY). These services are still being adopted by a growing number of universities at various geographic locations. In the new century, SMPY-type programs show promise of becoming so widespread that nearly every mathematically advanced child may eventually have easy access to rapid-paced instruction in all countries where universities are receptive to the model. SMPY is noteworthy not only because of its proven success and popularity but also on account of its longevity. Too many other efforts at addressing the learning speed and capacity of the gifted through direct instruction have been short-lived. Hopefully, SMPY will serve as an object lesson on how and why to preserve effective services for the gifted in the next century, not only in mathematics but in all vital disciplines.

At the University of Connecticut, Joseph S. Renzulli continues to direct *The National Research Center on the Gifted and Talented* (NRCG/T), a consortium of four tertiary education institutions, including his own, Yale University, and the Universities of Georgia and Virginia. Besides building up a sizeable record of field service, research, and publication of position papers on various critical issues over the past decade, NRCG/T is anticipating its mission for the beginning of the next century by having issued a comprehensive needs assessment, based on reports of no fewer than 13,749 respondents, revealingly titled *Setting an Agenda: Research Priorities for the Gifted and Talented Through the Year 2000* (Renzulli, Reid & Gubbins, 1992). Judging from the survey's scope and detail, and subsequent staff planning, NRCG/T—indeed the entire field of giftedness and its nurture—faces a huge agenda in the years ahead (see NRCG/T Newsletter, Fall 1999). The University of Connecticut also sponsors its yearly so-called 'Confratute' on the gifted, which is a huge attraction to educators seeking to learn from, and interact with, some of the best-known figures in the field.

The *Belin-Blank Center*, headed by Nicholas Colangelo at The University of Iowa, has also attracted worldwide attention to its biennial *Wallace Symposia* featuring lecturers on topics that are both directly and inferentially related to the gifted. The range of its study opportunities is so extensive that many targeted children and adults have been reached by them. For

example, in his *Comprehensive Report 1980–1999*, Colangelo notes that in the last two decades over 20,000 school-age students have participated in the Center's talent searches, more than 5,000 students have attended its summer programs, and some 2,000 teachers have been enrolled in its courses and workshops. Considering the Center's past accomplishments and plans for the future, there is no doubt that *Belin-Blank* services will continue and probably expand, at least in the early part of the twenty-first century.

Still another example of a higher education institution that has long been offering wide varieties of special education to gifted children and to elementary and secondary school personnel is Purdue University in Indiana, where *The Gifted Education Resource Institute* (GERI), founded by John F. Feldhusen in 1978, is located. Here too, as in a growing number of colleges and universities, there is a rich array of advanced and unconventional courses for gifted children of all ages. The schedule of these learning experiences avoids conflict with school hours and the school calendar. This separation prevents power disputes between the 'home' schools and the enrichment centers concerning who is responsible for instructing gifted children in any content area.

As yet, this 'division of labour' is only a partial blessing for the gifted. On the positive side, it expands the children's exposure to domains and depths and breadths of knowledge they might never have encountered, at least at their ages. It challenges them closer to the limits of their abilities than anything they study in regular classrooms. Moreover, the direct college-based service to the gifted is at least somewhat of an accommodation of Martin's (1996) argument that we are living in an age of cultural superabundance which makes it impossible for conventional schools alone to fully educate tomorrow's children, including the gifted. Other institutions have to share the burden of public education. Furthermore, even school buildings may some day become fairly insufficient as locales of study if distance learning is eventually geared to reach and educate unprecedented numbers of students. In that case, a vast, complex, internet-based school system would become the major medium for confronting knowledge overload in the twenty-first century.

The limitation of dividing education for the gifted between school and college is that the two efforts are usually independent of each other rather than shared or coordinated. Elementary and secondary school rarely collaborate with colleges to offer an interrelated program to able children, a total package as it were. Instead, the colleges often provide supplementary learning experiences without much care about what is being supplemented. Worse still, the regular schools hardly ever consult the supplemental program content in designing curriculum enrichment or to gain insight into the special interests and abilities of their gifted students. Sometimes, compulsory education defers or

defaults entirely to elective education to service the gifted, paying hardly any attention to what the gifted are experiencing in their after-school-hours studies. This failure of schools to fully assume its share of responsibility is a problem despite the impressive attendance at advocacy group conferences by more and more professionals interested in bright children. Perhaps these meetings amount to preaching to the converted, while the policy-making educationists and lay board members who need the orientation are not yet fully represented among the participants.

### *Expansion of Scholarly Activity*

Among the encouraging signs of concern about the gifted is the mounting volume of theory and research that relates to them directly or by inference. This is true both for Europe and the United States (Heller, 1997). It is also clear from Heller's 1997 report that both areas of the world share similar scholarly concerns. Even at well-attended professional conventions where giftedness is not a first priority, there is often a sprinkling of papers delivered on aspects of childhood precocity, its meaning, origins, cultivation, and development. Needless to say, the many regional, national, and international meetings on the gifted are filled with such reports. Furthermore, there are at least three major journals on the gifted and one on the creative in the United States alone, which, along with similar periodicals in other countries, provide ample outlets for professional papers on these subjects. To illustrate the magnitude of scholarly work in the field, one educational psychologist, Kurt A. Heller, a co-editor of this Handbook, is credited or co-credited with no fewer than 91 publications, including books (written and edited), book chapters, journal articles, and scholarly papers published or delivered over a span of merely five years, 1995–1999. All of this material relates to the gifted, most of it directly, some indirectly. In addition, Heller has been readying nine reports for dissemination in the years 2000 and one in 2001. His total, so far, since 1995, and probably still growing: 101! Camilla P. Benbow and David Lubinski have likewise produced a large number of publications in recent years, reporting mostly on studies related to mathematical precocity, with present and former SMPY students as the subjects.

In the 1990s, and continuing into the next century, psycho-educational research and debate have concentrated heavily, though not exclusively, on long-standing, never-resolved issues. Still highly volatile is the familiar nature vs. nurture controversy relating to IQ, which has simmered for many years and was newly inflamed by the publication of *The Bell Curve*, by Herrnstein and Murray (1994). A major source of dissatisfaction among the book's critics is its claim that social success and failure depend heavily on individual differences in tested intelligence and that it

is impossible to achieve equity in education because some minority groups perform poorly on these measures (Fraser, 1995; Jacoby & Glauberman, 1995). Gould (1996) finds it preposterous to assert that a single metric can create a hierarchy of sorts among people and that the test score is genetically based and immutable. Some go so far as to denounce the book as a pseudoscientific attack against democratic ideals (Giroux & Searles, 1996).

Still, the barrage of criticism of *The Bell Curve* has not stifled arguments favoring nature over nurture and the importance of IQ in testing for giftedness in children. Despite Carroll's (1997) reasonably even-handed review of the Herrnstein–Murray thesis, in which he finds their data collection and analysis methods defensible but disagrees with the inferences they draw from the results, opinions on the issue have become mostly polarized. On the side of nature, Gottfredson (1998) states her view unequivocally, as follows: "We are born unequal in intellectual potential, and these differences portend social inequality in any reasonably free society. We may all be equal before the law and in the eyes of God, but we differ greatly in our abilities to perform well in school, work, and everyday life. Mother nature, it turns out, is not egalitarian. Gifted children are a stark reminder of this fact" (1998, p. 3).

One of the best-known advocates of the nature position is Judith Rich Harris, author of the much-discussed book, *The Nurture Assumption* (1998), which argues vigorously against the hitherto popular belief that caretakers' child-rearing strategies are critical in shaping children's personalities. Instead, the overwhelming influence at home is in the genes inherited from the parents. From an historical perspective, it doesn't matter that the study has been criticized by behavioral scientists (e.g. Williams, 1999; Plomin, 1999). Nor do too many people take notice of the work by Riksen and Walraven (1978) in Holland, Klein (1992) in Israel, and Moss (1992) in the United States on how effectively caretakers can enhance the cognitive development of infants and pre-schoolers through systematic mediation of the children's behavior. What matters is that the Harris thesis has received a plethora of media attention, much of it in the form of unrestrained endorsement. Perhaps the reason for the idea's current popularity is that it appeals to so many of today's parents who want to cast off the Freudian burden of responsibility for the kinds of people their offspring turn out to be, especially in cases where the children are considered 'bad seed'. These parents may prefer to feel complacent in the thought that 'molding' the genes they pass on to their young is impossible, rather than take heavy responsibility for 'molding' a healthy home environment to enrich their children's lives.

The role of media attention to the nature–nurture controversy is extremely powerful in influencing public

opinion, far more persuasive than the technical scholarly reports from which the media elicit knowledge and information. How it is presented for public consumption, specifically with what bias, if any, is of critical importance. Sometimes, coverage of professional papers in the popular press carries with it an air of finality that was never intended. For example, a study comparing the sexes in performance on the Scholastic Aptitude Test showed that more male than female bright seventh graders scored high in mathematical reasoning (Benbow and Stanley, 1980). Five years later, Jacobs and Eccles (1985) noted that two of the most widely read news magazines interpreted these outcomes to mean that genetic or other biological factors accounted for the discrepancy in performances. Eleven years later, Freeman (1996) reported that British schoolgirls were functioning on a par with their male peers in mathematics. In light of these more recent data, what credence can be attached to the original media coverage? More important, what can a twenty-year history of scholarship on gender differences in mathematical aptitude reveal about the relative power of nature and nurture, if such differences are not universal, or if they change dramatically over time?

Is it plausible to assert that the genetic mix powering mathematical achievement is stronger in British than in American females? Or is there something in British schools and society that forecloses a gap in mathematical achievement between British schoolgirls and schoolboys, whereas such a preventative doesn't exist in the United States? Hardly, on both counts. It would therefore seem that extreme convictions in the nature-nurture debate are rooted more in dogma than in empiricism. Probably the only reasonable way to deal with the nature vs. nurture polarization is to revive from the history of science an interaction hypothesis suggesting that nature and nurture are not in conflict but rather combine to reinforce each other. It doesn't really matter which is stronger, as long as it is understood that each is powerless without the other.

Similar psycho-social forces may also be operating in research on monozygotic and dizygotic twins, some reared together, others reared apart (Bouchard, Jr. & Lykken, 1999; Bouchard Jr., Lykken, Tellegen & McGue, 1996). These studies have produced seemingly powerful arguments favoring heredity as the key determinant of gifted behavior. The data show that environment contributes little to the variance; it can help a budding historiographer decide whether to focus on French or Chinese history, but it contributes little to that person's competence in whatever choice he or she makes. But here too, the finding that genetic factors soak up so much of the variance may result, surprisingly, from similarities between the lifestyles of homes where the experimental populations are born and homes where they are raised. Stoolmiller (1999) reviewed several adoption studies relating to IQ and antisocial behavior and discovered a narrow range of

differences between birthing and adoptive family environments. When corrections were made for range restrictions, the shared environment accounted for as much as 50% of the variance. Stoolmiller speculates that studies of adopted twins may also reveal a larger-than-expected portion of the variance explained by environments when range restrictions are corrected statistically. If evidence shows that home settings cannot be discounted, it may boost confidence in the role of education as a nurturing influence. Indeed, Ericsson and Charness (1994) have argued persuasively that skilled and imaginative training can stimulate expert performance effectively.

Again, a review of past and present scholarship on the nature-nurture controversy encourages even-handedness in the form of a revival of the long-neglected belief in the interdependence of both, to replace current orthodoxies about the supremacy of either.

Another seemingly perpetual debate that promises to continue well into the twenty-first century is between believers in general ability ('*g*') as the main source of vital mental functioning and those who point to separable aptitudes as the origins. Here again, socio-political differences, more than research evidence, may account for the rivalry. Those who emphasize the importance of *g* concentrate on human differences in the abilities that relate most strongly to *g* and are at the heart of every curriculum in sciences and letters. Whoever excels in these disciplines is deemed most likely to some day enlarge the world's knowledge bank and to preserve and advance cultural life on the planet. Discreditors of *g* focus mainly on diversity rather than just difference and prefer to show that more people can demonstrate excellence in at least one of a variety of aptitudes than in the restricted range of competencies subsumed under *g*. One side of the debate prides itself in being primarily selective in defining who qualifies as gifted, while the opposition seeks to be more inclusive and hence more egalitarian or expansive in formulating qualifications.

As would be expected, belief in the idea of multiple intelligences (Guilford, 1973; Gardner, 1983) is relatively popular, compared to favoring theories of general intelligence, since it would seem more equitable for the largest possible number of people to qualify as outstanding in any skill of more or less use to society. Sternberg (1997) calls attention to what he has labeled 'Successful Intelligence', or the ability to adapt to unfamiliar environments and their own practical challenges. His studies indicate that these abilities are not validly measured by conventional IQ tests, which are best suited for assessing *g*. Therefore, it is necessary to abandon *g*-centrism in identifying giftedness in the realm of successful intelligence, which is more closely related to practical, adaptive skills than to analytical or creative talents. However, some may wonder whether swift, ingenious adaptation to strange surroundings, often marked by 'street smarts', is an

adequate sign of sophistication that denotes the familiar domains of excellence.

Those who appreciate the importance of *g* typically base their conviction on empirical data showing that *g* explains a high proportion of the variance in special aptitude tests (e.g., Thorndike, 1985). Some proponents of separable abilities also use mass data examination, particularly factor analysis, to bolster their theory (Thurstone & Thurstone, 1941; Guilford, 1967). Howard Gardner's approach is more *ex-cathedra*, although he uses specific criteria for including abilities in his list of intelligences. Possibly because his list of qualifiers is subjective, albeit rational, but not yet subjected to objective confirmation, he is regarded as more of a theorist than empiricist. Still, his theory has been enormously appealing to classroom teachers, especially those who work with exceptionally bright children. Commercial publishers have produced and sold many packets of instructional materials to stimulate growth of each intelligence he has posited thus far. These practical aids seem ready to retain their popularity well into the new century, probably because they are theory-driven, and their content and format seem engaging enough to capture children's attention. It remains to be seen whether learning is deepened or accelerated by education in Gardner's multiple intelligences.

One of the most enduring successes in expanding the concept of giftedness has been accomplished through the build-up of theory and research on creativity. Ever since J. P. Guilford introduced his sense of urgency about the topic at mid-twenty-first century in his presidential address to the American Psychological Association (Guilford, 1950), it has become the subject of intense scientific speculation, empirical research, and classroom attention. Some of it was initiated by Guilford himself, but he has been succeeded by a large number of scholars, some of whom are poised to carry on their work well into the twenty-first century. For example, Mark A. Runco, co-editor of the *Encyclopedia of Creativity* (Runco & Pritzker, 1999), has served as editor of the *Creativity Research Journal* since 1988 and is instrumental in disseminating some of the most important papers on the subject through this publication. Dean Keith Simonton (1999) has introduced a unique historiometric approach to the study of creativity and will likely continue this enlightening work in the years ahead. Jonathan A. Plucker (Plucker & Runco, 1998; Plucker & Renzulli, 1999) has been leading an initiative to restore confidence in divergent thinking as essential to the understanding and measurement of creativity. So insightful and engaging is the work of these specialists, along with the efforts of other scholars (too many to list here), that hardly any student of giftedness would exclude creativity from its realm.

In essence, then, scholarship on the gifted is alive and vigorous at the turn of a new century. Most of the

subjects occupying the attention of theorists and researchers are not new, but are being addressed in innovative ways that generate new understandings for succeeding generations of scholars to accept, or build on, or dissent from, or replace with their own work. The twenty-first century promises to be the most exciting in history for future students of the gifted, thanks to the knowledge shared with them, and bequeathed to them, by their predecessors.

### A Postscript on the Future

How daunting is it to forecast change initiated by the gifted for the next hundred years? Consider the hazards of making such an attempt in 1900 for the twentieth century. At that time, it was unthinkable to anticipate success in inventing incandescent bulbs to light homes, communities, and work places; formulating theories of relativity to revolutionize the physical sciences; harnessing atomic energy for awesome destructive and constructive potential; designing telecommunication devices, including telephone, television, audio and video recording, and computer technology to connect people with lives, ideas, events, materials, and places anywhere on the planet; achieving breakthroughs in medicine to prevent and cure hitherto uncontrollable diseases and to habilitate the organism's bodily, mental, and social functioning for a prolonged, healthier life; devising air travel, eventually jet-propelled, to enable people and cargo to reach distant places in relatively short time, and to use such unprecedented transport power for deep probes into the universe; and creating a cornucopia of artistic, musical, literary, theatrical, dance, and movie masterpieces to add meaning and pleasure to human life. This is merely a small sample of the countless gifts from the gifted to humanity, all given within a span of only one hundred years.

And yet, even the brightest of men and women at the outset of the twentieth century could not predict what miracles of the mind would materialize in the lifetimes of their children, grandchildren, and great-grandchildren. But they must have sensed that if anything so dramatic were to happen in their new century, precocious children, nurtured to fulfill their extraordinary promise and to serve rather than disserve society, would deserve the credit. We face the same mixture of mystery and expectation as our new century unfolds.

# Giftedness as Developing Expertise

Robert J. Sternberg<sup>1</sup>

## Introduction

Mary has an IQ of 140 on a standardized individual intelligence test and has been identified as 'gifted'. Ellen has an IQ of 120 on the same test and has not been identified as gifted. What do each of these scores, and the difference between them, mean? In this chapter, it is argued that the best available answer to this question is quite different from the one that is conventionally offered, which is that the scores and the difference between them reflect some largely inborn, relatively fixed 'ability' construct. Instead, it is argued that the difference in scores reflects a difference in one of many kinds of developing expertise (Sternberg, 1998), a kind that is especially important for school performance but less important for job performance later in life.

The expertise that all these assessments measure is referred to as 'developing' rather than as 'developed' because expertise is typically not at an endstate, but in a process of continual development. Gifted individuals need continually to be developing the kinds of expertise that render them gifted. If they do not, they stop being identified as gifted, or they become identified as gifted 'has-beens'. Indeed, part of the argument of this chapter is that the kinds of distinction that lead one to be identified as gifted differ at different points in the life span, which is why many people are gifted in childhood but not thereafter. It is not that the gifted children somehow later lose what they had; it's that they never developed the kind of expertise that would lead them to be identified as gifted adults (see Bamberger, 1986).

In a sense, the point of view articulated in this chapter represents no major departure from some modern points of view regarding abilities (e.g. Anastasi & Urbina, 1997). Abilities are broadly conceived, and are seen as important to various kinds of success. They are seen as modifiable in some degree, and as capable of being flexibly implemented, at the same time that they are viewed as having interactive genetic and

environmental components. Of course, they are seen as important in giftedness, although only a part of it.

What is perhaps new here is the attempt to integrate three literatures—the literature on abilities, in general; the literature on giftedness, in particular; and the rather distinct literature on expertise. The abilities and expertise literatures, especially, may be talking, at some level, about the same thing, rather than about distinct constructs or even, as some believe, constructs in opposition (see Ericsson, 1996).

## The Relation of Abilities to Expertise

Traditionally, abilities are typically seen either as (a) precursors to expertise (see essays in Chi, Glaser & Farr, 1988) or (b) as opposed to expertise (Fiedler & Link, 1994) as causes of behavior. Sometimes, abilities are held up (c) as causes of developing expertise in contrast to deliberate practice (see also Ericsson, Krampe & Tesch-Romer, 1993, who argue for the importance of the latter as opposed to the former). Here, abilities are seen as themselves a form of developing expertise. An important educational implication of this view is that abilities, like expertise, can be developed. It therefore follows that giftedness can be developed.

When we test for abilities in order to identify gifted individuals, we are as much testing a form of expertise as we are when we test for accomplishments of various kinds, whether academic achievement, skill in playing chess, skill in solving physics problems, or whatever. What differs is the kind of expertise we measure, and more importantly, our conceptualization of what we measure. The difference in conceptualization comes about in part because we happen to view one kind of accomplishment (ability-test scores) as predicting another kind of accomplishment (achievement test scores, grades in school, or other indices of accomplishment). But according to the present view, this conceptualization is one of practical convenience, not of psychological reality.

Consider, as an example, solving problems on a verbal-analogies test or a test of mathematical problem solving. Solving such problems requires expertise, just as does any other kind of problem solving. Moreover,

E-mail: robert.sternberg@yale.edu

the components of information processing on many of these kinds of tasks are highly overlapping (Sternberg, 1983, 1985; Sternberg & Gardner, 1983).

According to this view, although ability tests may have temporal priority relative to various criteria in their administration (i.e. ability tests are administered first, and later, criterion indices of performance, such as grades or achievement test scores, are collected), they have no psychological priority. All of the various kinds of assessments are of the same kind psychologically. What distinguishes ability tests from the other kinds of assessments is how the ability tests are used (usually, predictively), rather than what they measure. There is no qualitative distinction among the various kinds of assessments. When we believe that ability tests and achievement tests give us distinct insights into giftedness, we are wrong: Both kinds of tests measure largely the same construct, which is why ability and achievement tests correlate about as highly with each other as they do among themselves.

For example, verbal-analogies tests and mathematical problem-solving tests could be, and often are, used as predictors; but they could as well be predicted by other kinds of measures, such as school performance or other measures of achievement. Indeed, the murkiness of the distinction between abilities and achievement is shown by the fact that some of the types of items that appear as ability-test items (e.g. vocabulary) on one measure appear as achievement test items on another measure. For example, the *Kaufman Assessment Battery for Children* (Kaufman & Kaufman, 1983) labels as measuring achievement verbal items that the *Stanford-Binet Intelligence Scale* (Thorndike, Hagen & Sattler, 1986) labels as measuring abilities.

If we look at current theories of intelligence, we find they make a similar point. Conventional ability and achievement tests both measure largely analytical abilities and their outcomes according to Sternberg's (1985) theory and measure largely linguistic and logical-mathematical abilities and their outcomes according to Gardner's (1983) theory. Moreover, the kinds of outcomes they measure are limited by their paper-and-pencil format and by the narrow range of skills tested. Thus, these tests can identify only a narrow band of those who are gifted.

Although individual and group tests of intelligence are administered differently, they measure roughly the same skills and have underlying them the same theories of intelligence (Sternberg, 1990; Gustafsson & Undheim, 1996; Daniel, 1997). Thus, in this discussion, individual and group tests are considered jointly.

The literatures on abilities and expertise have grown up largely separately, with studies of ability testing dating back to work done by Binet and his colleagues (Binet & Simon, 1916) on children and studies of expertise dating back to work of DeGroot (1965) done on adults. The giftedness literature has grown up in tandem with the abilities literature, dating back at least

to the Terman studies (e.g. Terman, 1925). But the suggestion here is that the giftedness literature needs also to be aligned with the expertise literature, because in adulthood, expertise is what giftedness is really about. At any age, gifted individuals have always developed some kind of extraordinary expertise. In school, expertise in taking tests may be sufficient to label one as gifted. In adulthood, it almost never is. Little wonder, then, that there is only very partial overlap between who is identified as gifted in childhood versus adulthood.

### **A Model of Individuals' Abilities and Achievements**

The model of abilities driving the present work is the triarchic theory of human intelligence and intellectual giftedness (Sternberg, 1984, 1985, 1988, 1996d). According to this theory, abilities take the form of various information processes operating upon mental representations at varying levels of experience in order to adapt to, shape, and select environments (see Sternberg, 1985, for more details). It is important to note, however, that one could accept the model of abilities as forms of developing expertise, in general, without accepting the triarchic theory, in particular. Where does the developing-expertise model lead us, both in terms of educational opportunities and in terms of societal outcomes for gifted individuals? One place it leads is to a view of abilities as flexible rather than fixed.

There is now substantial evidence that abilities are modifiable, at least in some degree (see Feuerstein, 1980; Nickerson, Perkins & Smith, 1985; Herrnstein, Nickerson, deSanchez & Swets, 1986; Nickerson, 1986; Sternberg, 1988, 1994a, 1996d; Ramey, 1994; Perkins, 1995; Sternberg & Spear-Swerling, 1996; Perkins & Grotzer, 1997). If they are, then we should probably hesitate to assign any individual to a fixed group, whether it be a 'cognitive elite' (Herrnstein & Murray, 1994) or any other. The best evidence, of course, is in favor of both genetic and environmental origins of intelligence, interacting in ways that are not, as yet, fully known (see Sternberg & Grigorenko, 1997). There is no one set of 'gifted individuals', on this view. People can become gifted by developing various kinds of expertise. But the kind of expertise they will need to be identified as gifted will change throughout their life span.

#### *The Developing-Expertise Model of Abilities*

There are views of abilities and their implications that diverge substantially from fixed-abilities views such as those advocated and reviewed by Herrnstein and Murray (1994). For example, Snow (1979, 1980, 1996; Snow & Lohman, 1984) presented a much more flexible view of human abilities, according to which abilities are not limited to the cognitive domain, and also overlap with aptitudes and achievements. Ceci

(Ceci, Nightingale & Baker, 1992; Ceci & Roazzi, 1994; Ceci, 1996) has proposed a bioecological model of abilities that shares some features with the view presented here, particularly with regard to the relevance of domains. Perkins (1995) and Renzulli (1986) have also proposed compatible views. The model presented here perhaps extends some of these views in its emphasis on abilities and hence gifted levels of abilities as representing developing forms of expertise.

*Abilities as developing expertise.* This alternative model sees scores on ability tests as measuring a form of developing expertise, much as would be represented by chess performance (Chase & Simon, 1973), physics performance (Chi, Glaser & Rees, 1982; Larkin, McDermott, Simon & Simon, 1980), radiology performance (Lesgold, 1984), teaching performance (Shulman, 1987; Livingston & Boriko, 1990; Sabers, Cushing & Berliner, 1991; Sternberg & Horvath, 1995), or any of a number of other kinds of expertise (Bereiter & Scardamalia, 1993).

One comes to be an expert in the skills needed for success on ability tests in much the same ways one becomes an expert in doing anything else—through a combination of genetic endowment and experience. A gifted individual is thus someone who has developed and is continuing to develop a set of societally valued skills, using both the genetic and environmental resources available to him or her. Of course, people with more privileges and opportunities in their environment are at an advantage in developing expertise.

Expertise involves the acquisition, storage, and utilization of at least two kinds of knowledge: explicit knowledge of a domain and implicit or tacit knowledge of a field (see Sternberg et al., 1995), where *domain* refers to a knowledge base and *field* to the social organization of that knowledge base (Csikszentmihalyi, 1988, 1996). Explicit knowledge is the kind most frequently studied in the literature on expertise (see Chi, Glaser & Farr, 1988; Ericsson & Smith, 1991). It is knowledge of the facts, formulas, principles, and major ideas of a domain of inquiry. Implicit or tacit knowledge of a field is the knowledge one needs to know to attain success in a field that usually isn't talked about or even put into verbal form. For example, in psychology, Freud's theory of depression would constitute explicit knowledge, whereas how to get a grant would constitute informal or tacit knowledge. Giftedness in a domain (subject matter) may involve just explicit knowledge, but giftedness in a field (the social organization of subject matter) always involves tacit knowledge about the field as well (see Csikszentmihalyi, 1996). Children develop a variety of different kinds of expertise. Society places demands when it expects specialization, but individuals can and do make their own decisions. Virtually any kind of domain-related expertise can be incorporated into the purview of the school.

When abilities are measured, both explicit and implicit elements are involved. A verbal-analogies test, for example, measures explicit knowledge of vocabulary and reasoning with this knowledge, but the test also measures implicit knowledge of how to take a test. For example, one has to work within certain time constraints, choose the best of what often are all imprecise options, and so on. The connection between explicit and implicit knowledge can be fluid, as shown by the fact that courses are sometimes constructed to make implicit knowledge, explicit (see e.g. The Practical Intelligence for School Program of Williams et al., 1996). Gifted individuals may have tremendous domain knowledge but fail to utilize it effectively if they do not have the implicit knowledge of a field (which includes the workings of a school) that enables them best to exploit their domain-based knowledge.

*Characteristics of expertise.* The characteristics of experts as reflected in performance on ability tests are similar to the characteristics of experts of any kind (see Chi, Glaser & Farr, 1988; Sternberg, 1996a). Expertise is a prototypically rather than classically defined concept (Sternberg, 1994a). Operationally, by *expertise*, I refer, in a given domain, to a prototype of people's: (a) having large, rich schemas (organized networks of concepts) containing a great deal of declarative knowledge about a given domain, in the present case, the domains sampled by ability tests; (b) having well-organized, highly interconnected (mutually accessible) units of knowledge about test content stored in schemas; (c) spending proportionately more time determining how to represent test problems than they do in search for and in executing a problem strategy (Larkin, McDermott, Simon & Simon, 1980); (d) developing sophisticated representations of test problems, based on structural similarities among problems; (e) working forward from given information to implement strategies for finding unknowns in the test problems; (f) generally choosing a strategy based on elaborate schemas for problem strategies; (g) having schemas containing a great deal of procedural knowledge about problem strategies relevant in the test-taking domain; (h) having automatized many sequences of steps within problem strategies; (i) showing highly efficient problem solving; when time constraints are imposed, they solve problems more quickly than do novices; (j) accurately predicting the difficulty of solving particular test problems; (k) carefully monitoring their own problem-solving strategies and processes; and (l) showing high accuracy in reaching appropriate solutions to test problems. Rather than defining gifted individuals as simply high in some kind of abstract ability, the proposed notion defines them in terms of very high levels of these particular aspects of expertise.

Ability tests, achievement tests, school grades, and measures of job performance all reflect overlapping

kinds of expertise in these kinds of skills. To do well in school or on the job requires a kind of expertise; but to do well on a test also requires a kind of expertise. Of course, part of this expertise is the kind of test-wiseness that has been studied by Millman, Bishop & Ebel (1965) and others (see Bond & Harman, 1994); but there is much more to test-taking expertise than test-wiseness.

Return, for a moment, to Mary and Ellen. Mary and Ellen test differently on an IQ test. This difference in test scores may reflect a number of factors: differential test wiseness, differential test anxiety, differential enculturation into a culture that values IQ tests, differential mood and alertness on the day of testing, differential readiness to take the test, and most importantly, differential developing expertise in the skills that the test measures. Only the last of these differences reflects a true difference in who properly should be identified as gifted.

People who are more expert in taking IQ-related tests have a set of skills that is valuable not only in taking these tests, but in other aspects of Western life as well. Taking a test, say, of verbal or figural analogies, or of mathematical problem solving, typically requires skills such as (a) puzzling out what someone else (here, a test constructor) wants, (b) command of English vocabulary, (c) reading comprehension, (d) allocation of limited time, (e) sustained concentration, (f) abstract reasoning, (g) quick thinking, (h) symbol manipulation, and (i) suppression of anxiety and other emotions that can interfere with test performance, among other things.

These skills are also part of what is required for successful performance in school and in many kinds of job performance. Thus, an expert test-taker is also likely to have skills that will be involved in other kinds of expertise as well, such as expertise in getting high grades in school. These kinds of expertise also matter in the work of adults, but perhaps less than in the schoolhouse. It is for this reason, again, that the child expert often does not become the adult expert.

It is, in my opinion, not correct to argue that traditional intelligence tests measure little or nothing of interest. Moreover, the tests do not all measure exactly the same constructs, although they measure related constructs. Clearly, these tests tap some range of cognitive abilities. At the same time, there are many important kinds of expertise that the tests do not measure (Gardner, 1983; Sternberg, 1985; Das, Naglieri & Kirby, 1994), for example, what Gardner (1983, 1993) would call musical, bodily-kinesthetic, interpersonal, and intrapersonal intelligences, and what I would call creative and practical intelligence (Sternberg, 1985, 1988, 1996d). These other kinds of expertise probably matter more in later life than in school. For example, an expert musician might not be identified as gifted in the school, but if he or she becomes an expert musician as an adult, will almost

certainly be identified as a gifted musician. The individual may be a wonderful dancer without the school's even knowing about it. Later in life, though, when this individual becomes a dancer, he or she will be identified as a gifted dancer.

Contrariwise, the individual who is an expert at solving given mathematics problems but who cannot recognize what problems are worth solving may be identified as gifted during youth, but is less likely to be identified as a gifted mathematician upon reaching adulthood. Similarly, the history student who can memorize all the facts in the middle-school history text may appear to be gifted at the middle-school level, but without accompanying analytical and creative skills, is unlikely to be identified as a gifted historian later on. The kinds of developing expertise required to be identified as gifted simply change. By using the single word 'gifted', we confuse the type (the word) with the token (the concept).

To the extent that the expertise required for one kind of performance overlaps with the expertise required for another kind of performance, there will be a correlation between performances. The construct measured by the ability tests is not a 'cause' of school or job expertise; it is itself an expertise that overlaps with school or job expertise. On the overlapping-expertise view, the traditional notion of test scores as somehow causal is based upon a confounding of correlation with causation. Differences in test scores, academic performance, and job performance are all effects—of differential levels of expertise.

*Acquisition of expertise.* The literature on the acquisition of expertise, in general, is reviewed in Ericsson (1996). How does this development relate to abilities, and to gifted levels of abilities, in particular?

Individuals gain the expertise to do well on ability tests in much the same way they gain any other kind of expertise—through the interaction of whatever genetic dispositions they bring to bear with experience via the environment. Tests measure *developing* expertise because the experiential processes are ongoing. In particular, individuals (a) receive direct instruction in how to solve test-like problems, usually through schooling; (b) engage in actual solving of such problems, usually in academic contexts; (c) engage in role modeling (watching others, such as teachers or other students, solve test-like problems), (d) think about such problems, sometimes mentally simulating what they might do when confronting such problems; and (e) receive rewards for successful solution of such problems, thereby reinforcing such behavior.

It is interesting to compare the acquisition of test-taking expertise with the acquisition of the kinds of expertise that will matter in adulthood, because the processes by which a person becomes gifted seem to be somewhat different.

First, once direct instruction in school is over (point (a) above), direct instruction in one's life is likely to diminish or vanish. What it takes to be a gifted expert artist, musician, scientist, or teacher as an adult goes well beyond the instruction one receives during the period of schooling. One needs to acquire a kind of productive expertise that goes beyond the reproductive expertise that may earn one identification as gifted in one's youth.

Second, the kinds of problem solving one does in adulthood often differs from the kinds of problem solving done in childhood (point (b) above). In particular, in adulthood the problems are not given to one in quite the same way as they are during childhood. In school, problems are presented in textbooks, on tests, in the classroom, and so on. In adulthood, the problems solved by teachers in the classroom, by physicists in the laboratory, by composers writing sonatas, or by entrepreneurs trying to start up a business are not handed to them directly. Often the hardest part of dealing with problems in adulthood is recognizing that they exist, and then, what their nature is. Adult giftedness requires sophisticated problem-recognition and problem-definition skills.

Third, although role modeling continues through adulthood, the time of life when perfect or near-perfect imitation of a role will lead to identification as gifted has ended (point (c) above). Indeed, a professional who does no more than perfectly imitate a mentor is likely to be viewed as nothing more than some kind of unimaginative clone, and certainly not as gifted.

Fourth, the mental simulations needed for success differ in school and in the world of work (point (d) above). In school, simulation often means reconstructing an algorithm one has learned from a teacher or a textbook (such as to solve a difficult mathematics problem or to write a term paper that basically follows guidelines a teacher has set out). In the world of work, simulation often means constructing one's own algorithms and heuristics and trying them out mentally before actually implementing them.

Fifth, the kind of feedback one typically receives in the world of work is quite different from that typically received in school (point (e) above). In school, most feedback is immediate and direct, often taking the form of a letter grade or other evaluation of a piece of work that has been turned in. In the world of work, feedback is much more sporadic, often indirect, and often extremely ambiguous. One needs much more sophisticated skills for monitoring and evaluating one's performance (Sternberg, 1985). Gifted individuals are able to take advantage of feedback to tune already exceedingly high levels of performance.

In sum, the processes that lead to successful development of high and indeed gifted levels of expertise differ between the worlds of school and of work. Little wonder that different people often end up being identified as gifted in the two different worlds.

*Individual differences in expertise.* Of course, there may be substantial differences in underlying capacities. The problem, as recognized by Vygotsky (1978), as well as many others, is that we do not know how directly to measure these capacities. Measures of the zone of proximal development (e.g. Brown & French, 1979; Feuerstein, 1979; Brown & Ferrara, 1985; Grigorenko & Sternberg, 1998) seem to assess something other than conventional psychometric *g*, but it has yet to be shown that what it is they do measure is the difference between developing ability and latent capacity.

Individual differences in expertise may stem from differences in rate of learning and ultimate asymptote, which are in turn likely to depend upon one's ability to learn from the way material is taught (see Sternberg, Ferrari, Clinkenbeard & Grigorenko, 1996; Sternberg, Torff & Grigorenko, 1998a, 1998b; Sternberg, Grigorenko, Ferrari & Clinkenbeard, 1999). But material is 'taught' in very different ways in the schools of one's youth versus the school of life. Our work on tacit knowledge finding little or no correlation between academic and practical intelligence (Sternberg, Wagner, Williams & Horvath, 1995) suggests that the people who learn well in school are not necessarily those who learn well in life. So again, who becomes gifted can depend a great deal on stage of life.

There is no compelling evidence that individual differences can be wiped out by the kind of 'deliberate practice' studied by Ericsson and his colleagues (e.g. Ericsson & Smith, 1991; Ericsson, Krampe & Tesch-Romer, 1993; Ericsson & Charness, 1994). Ericsson's work shows a correlation between deliberate practice and expertise; it does not show a causal relation, any more than the traditional work on abilities shows causal relations between measured abilities and expertise. A correlational demonstration is an important one; it is not the same as a causal one. Thus, the concept of giftedness will always be with us. No one has shown a way to wipe out individual differences.

The fact that experts have tended to show more deliberate practice than novices may itself reflect an ability difference (Sternberg, 1996b). Meeting with success, those with more ability may practice more; meeting with lesser success, those with lesser ability may give up. Or both deliberate practice and ability may themselves be reflective of some other factor, such as parental encouragement, which could lead both to the nurturing of an ability and to deliberate practice. Indeed, deliberate practice and expertise may interact bidirectionally, so that deliberate practice leads to expertise, and the satisfaction brought by expertise leads to more deliberate practice. The point is that a variety of mechanisms might underlie a correlational relationship. It seems unquestionable that deliberate practice plays a role in the development of gifted levels of expertise. But it also seems extremely likely that its role is as a necessary rather than sufficient condition.

Deliberate practice may play a somewhat lesser role in creative giftedness than in other kinds of giftedness (Sternberg, 1996b). We might argue over whether someone who practices memorization techniques can become a mnemonist. Probably, the individual can become a mnemonist at least within certain content domains (Ericsson, Chase & Faloon, 1980). Ericsson and his colleagues, for example, were able to work with a college student so that he attained truly impressive expertise in memorizing strings of digits, but his memorization of strings of letters was ordinary. The reason was that he could use the mnemonic of running times to memorize digits but not letters. He may have been an expert, but he was a limited expert and certainly not a gifted one.

Even limited practice effects do not seem to apply quite so well in other domains. It seems less plausible that someone who practices composing a lot will become a Mozart. Of course, one could always conveniently maintain that we have not proven that someone could not become a Mozart with sufficient deliberate practice. Null hypotheses do not lend themselves to proof. But in the real world, with many millions having practiced music very hard, the evidence to date appears discouraging.

Other factors seem far more important in the development of the kind of giftedness that is represented by creative expertise, in whatever field. These factors include pursuing paths of inquiry that others ignore or dread, taking intellectual risks, persevering in the face of obstacles, and so on (Sternberg & Lubart, 1995, 1996).

#### *Relations Among Various Kinds of Expertise and Giftedness*

There are various measures that correlate with IQ that do not, on their face, appear to be measures of achievement. But they are measures of forms of developing expertise. For example, the inspection-time task used by Nettelbeck (1987; Nettelbeck & Lally, 1976) to measure intelligence or the choice reaction-time task of Jensen (1982) both correlate with psychometric *g*. However, performances on both tasks reflect a form of developing expertise, in one case, of perceptual discriminations, in the other case, of quick responses to flashing lights or other stimuli. Of course, individuals may differ in the slopes and asymptotes of their acquisition functions.

An examination of the content of tests of intelligence and related abilities reveals that IQ-like tests measure achievement that individuals should have accomplished several years back. Tests such as vocabulary, reading comprehension, verbal analogies, arithmetic problem solving, and the like are all, in part, tests of achievement. Even abstract-reasoning tests measure achievement in dealing with geometric symbols, skills taught in Western schools (Laboratory of Comparative Human Cognition, 1982). One might as well use

academic performance to predict ability-test scores. The problem with regard to the traditional model is not in its statement of a correlation between ability tests and other forms of achievement, but in its proposal of a causal relation whereby the tests reflect a construct that is somehow causal of, rather than merely temporally antecedent to, later success. Thus, as stated earlier, ability and achievement tests do not provide anything approaching independent assessments of giftedness.

Even psychobiological measures (see, e.g. Vernon, 1990) are in no sense 'pure' ability measures, because we know that just as biological processes affect cognitive processes, so do cognitive processes affect biological ones. Learning, for example, leads to synaptic growth (Thompson, 1985; Kandel, 1991). Thus, biological changes may themselves reflect, in part, developing expertise. Thus, 'better biology' does not always lead to giftedness. Giftedness may lead to 'better biology'.

If we viewed tested abilities as forms of what is represented by the term *developing expertise*, then there would be no argument with the use of the term *abilities*. The problem is that this term is usually used in another way—to express a construct that is psychologically prior to other forms of expertise. Such abilities may well exist, but we can assess them only through tests that measure developing forms of expertise expressed in a cultural context. There is no a priori test of who is gifted, only a posteriori ones.

In sum, the present argument differs from the conventional one in rejecting the psychological priority of abilities or of giftedness. Even those who believe that abilities are developing may view them as somehow prior to achievement; on the present view, both abilities and achievement—and hence, giftedness—are forms of developing expertise. None is psychologically prior, although there may be temporal priority in a protocol of assessment.

#### **The Specifics of the Developing-Expertise Model**

The specifics of the developing-expertise model are shown in Fig. 1. At the heart of the model is the notion of *developing expertise*—that individuals are constantly in a process of developing expertise when they work within a given domain. They may and do, of course, differ in rate and asymptote of development. The main constraint in achieving expertise is not some fixed prior level of capacity, but purposeful engagement involving direct instruction, active participation, role modeling, and reward.

#### *Elements of the Model*

The model of developing expertise has five key elements (although certainly they do not constitute an exhaustive list of elements in the development of expertise): metacognitive skills, learning skills, thinking skills, knowledge, and motivation. All of these

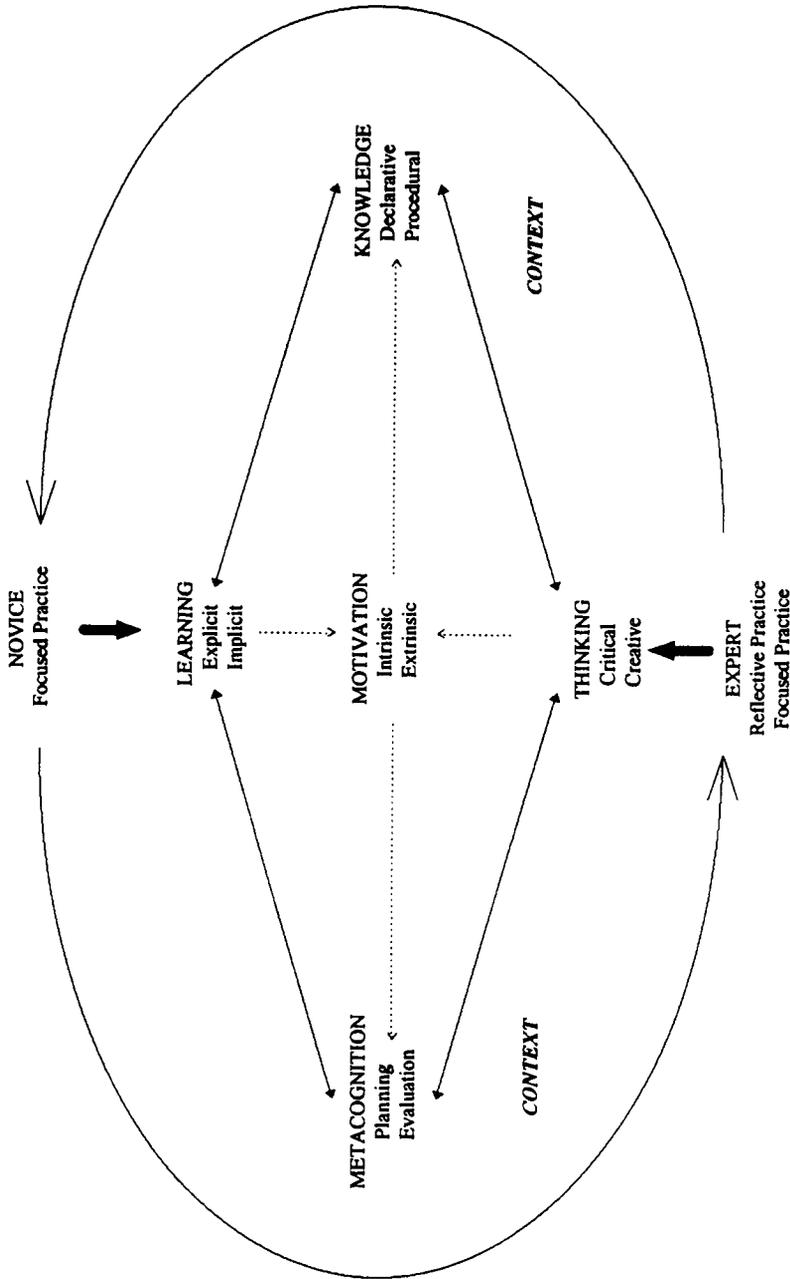

Figure 1. Developing Expertise Model

attributes have been associated in the past, individually or in various combinations, with giftedness (see Sternberg & Davidson, 1984). Although it is convenient to separate these five elements, they are fully interactive, as shown in the figure. They influence each other, both directly and indirectly. For example, learning leads to knowledge, but knowledge facilitates further learning.

*1. Metacognitive skills.* Metacognitive skills (or metacomponents—Sternberg, 1985) refer to people's understanding and control of their own cognition and are an important element of giftedness (Borkowski & Peck, 1986; Jackson & Butterfield, 1986). For example, such skills would encompass what an individual knows about writing papers or solving arithmetic word problems, both with regard to the steps that are involved and with regard to how these steps can be executed effectively. Seven metacognitive skills are particularly important: problem recognition, problem definition, problem representation, strategy formulation, resource allocation, monitoring of problem solving, and evaluation of problem solving (Sternberg, 1985, 1986). All of these skills are modifiable (Sternberg, 1986, 1988; Sternberg & Spear-Swerling, 1996).

*2. Learning skills.* Learning skills are also important elements of giftedness (Sternberg, 1984; Davidson, 1986; Feldhusen, 1986). Learning skills (knowledge-acquisition components) are essential to the model (Sternberg, 1985, 1986), although they are certainly not the only learning skills that individuals use. Learning skills are sometimes divided into explicit and implicit ones. Explicit learning is what occurs when we make an effort to learn; implicit learning is what occurs when we pick up information incidentally, without any systematic effort. Examples of learning skills are selective encoding, which involves distinguishing relevant from irrelevant information; selective combination, which involves putting together the relevant information; and selective comparison, which involves relating new information to information already stored in memory (Sternberg, 1985).

*3. Thinking skills.* Thinking skills are also essential to giftedness (Borkowski & Peck, 1986; Jackson & Butterfield, 1986; Stanley & Benbow, 1986; Sternberg, 1984). There are three main kinds of thinking skills (or performance components) that individuals need to master (Sternberg, 1985, 1986, 1994b). It is important to note that these are sets of, rather than individual, thinking skills. Critical (analytical) thinking skills include analyzing, critiquing, judging, evaluating, comparing and contrasting, and assessing. Creative thinking skills include creating, discovering, inventing, imagining, supposing, and hypothesizing. Practical thinking skills include applying, using, utilizing, and practicing (Sternberg, 1997). They are the first step in the translation of thought into real-world action.

*4. Knowledge.* Giftedness requires knowledge (Gruber, 1986). There are two main kinds of knowledge that are relevant in academic situations. Declarative knowledge is of facts, concepts, principles, laws, and the like. It is 'knowing that'. Procedural knowledge is of procedures and strategies. It is 'knowing how'. Of particular importance is procedural tacit knowledge, which involves knowing how the system functions in which one is operating (Sternberg, Wagner, Williams & Horvath, 1995).

*5. Motivation.* Motivation is an important part of giftedness (Feldhusen, 1986; Haensly, Reynolds & Nash, 1986; Renzulli, 1986; Gardner, 1994). One can distinguish among several different kinds of motivation. A first kind of motivation is achievement motivation (McClelland, Atkinson, Clark & Lowell, 1976; McClelland, 1985). People who are high in achievement motivation seek moderate challenges and risks. They are attracted to tasks that are neither very easy nor very hard. They are strivers—constantly trying to better themselves and their accomplishments.

A second kind of motivation is competence (self-efficacy) motivation, which refers to persons' beliefs in their own ability to solve the problem at hand (Bandura, 1977, 1996). Experts need to develop a sense of their own efficacy to solve difficult tasks in their domain of expertise. This kind of self-efficacy can result both from intrinsic and extrinsic rewards (Amabile, 1996; Sternberg & Lubart, 1996). Of course, other kinds of motivation are important too. Indeed, motivation is perhaps the indispensable element needed for school success. Without it, the student never even tries to learn.

*6. Context.* Giftedness attains meaning from a context (Csikszentmihalyi & Robinson, 1986; Haensly, Reynolds & Nash, 1986; Tannenbaum, 1986). All of the elements discussed above are characteristics of the learner. Returning to the issues raised at the beginning of this document, a problem with conventional tests is that they assume that individuals operate in a more or less decontextualized environment. A test score is interpreted largely in terms of the individual's internal attributes. But a test measures much more, and the assumption of a fixed or uniform context across test-takers is not realistic. Contextual factors that can affect test performance include native language, emphasis of test on speedy performance, importance to the test taker of success on the test, and familiarity with the kinds of material on the test.

#### *Interactions of Elements*

The novice works toward expertise through deliberate practice. But this practice requires an interaction of all five of the key elements. At the center, driving the elements, is motivation. Without it, the elements remain inert. Eventually, one reaches a kind of

expertise, at which one becomes a reflective practitioner of a certain set of skills. But expertise occurs at many levels. The expert first-year graduate or law student, for example, is still a far cry from the expert professional. People thus cycle through many times, on the way to successively higher levels of expertise. They do so through the elements in the figure.

Motivation drives metacognitive skills, which in turn activate learning and thinking skills, which then provide feedback to the metacognitive skills, enabling one's level of expertise to increase (see also Sternberg, 1985). The declarative and procedural knowledge acquired through the extension of the thinking and learning skills also results in these skills being used more effectively in the future.

All of these processes are affected by, and can in turn affect, the context in which they operate. For example, if a learning experience is in English but the learner has only limited English proficiency, his or her learning will be inferior to that of someone with more advanced English-language skills. Or if material is presented orally to someone who is a better visual learner, that individual's performance will be reduced.

### Conclusion

The model proposed in this chapter is one of abilities, in general, and gifted levels of abilities, in particular, as forms of developing expertise. Individuals are viewed as novices capable of becoming experts in a variety of domains. A model of fixed individual differences, which essentially consigns some students to fixed levels of instruction based on supposedly largely fixed abilities, can be an obstacle to the acquisition of expertise. The key to developing expertise is purposeful and meaningful engagement in a set of tasks relevant to the development of expertise, something of which any individual is capable in some degree. For various reasons (including, perhaps, genetic as well as environmentally based differences), not all individuals will equally engage or engage equally effectively, and hence, individuals will not necessarily all reach the same ultimate level of expertise. But they should all be given the opportunity to reach new levels of competence and perhaps even giftedness well beyond what they, and in some cases, others may have thought were possible for them. The fact that Mary and Ellen have different IQs tells us something about differences in what they now do. It does not tell us anything fixed about what ultimately they will be able to do, and which, if either of them, will be identified as a gifted adult.

# Understanding the Complex Choreography of Talent Development Through DMGT-Based Analysis

François Gagné

## Introduction

In the first edition of this handbook (Gagné, 1993), I addressed two basic issues in the field of gifted education: (1) How should we define the key concepts of giftedness and talent? (2) How large is the population of gifted and talented individuals? As a response to the first question, I introduced my Differentiated Model of Giftedness and Talent (DMGT), whose six components (gifts, talents, intrapersonal catalysts, environmental catalysts, chance as well as learning and practising) cover all the variables relevant to the analysis of talent development. Concerning the prevalence problem, I proposed a generous threshold, namely the top 15% on any ability measure; to that minimum threshold was added a system of four progressively more selective levels, based on the first four standard deviations of the normal curve. Since the publication of the first edition of the *International Handbook*, the DMGT has undergone no major transformations. The only substantial change has involved the prevalence issue. Not only did I adopt a slightly more selective threshold (10%), but also I proposed a 5-level system of categories based on the metric system (Gagné, 1998). Recently, I tried to anchor more solidly the differentiated nature of gifts and talents, by explaining in more detail what was meant by the concepts of natural abilities (NAT) and systematically developed ones (SYSDEV). The operationalization of the NAT vs. SYSDEV dichotomy, as well as their relationship to the concepts of giftedness and talent took the form of a set of 22 logically interconnected statements, each accompanied by detailed comments (Gagné, 1999c). That text was discussed by five colleagues (Borland, 1999; Detterman & Ruthsatz, 1999; Feldman, 1999; Hany, 1999; Robinson, 1999); a rejoinder (Gagné, 1999a) completed that special issue of the *Journal for the Education of the Gifted*.

For this second edition of the *International Handbook*, I have chosen not to write a strict update of the

1993 chapter, but to discuss instead some practical uses for this model of talent development. My main purpose will be to describe the DMGT's usefulness as an analytical tool, what will be called *DMGT-based analysis*. It describes the way this model can serve to examine in a very systematic way various types of data related to the process of talent development: journal articles, research reports, lists of variables, biographical information, interview data, and so forth. It is my belief that the DMGT can be a valuable framework to classify information into appropriate causal categories. Thanks to that classification, it can help better understand the dynamic interplay between the five causal factors during that long period from the time individuals decide to systematically develop a set of skills in a particular field of human activity until they achieve some level of excellence within that field. I intend to remain at a molar level, that of the major events that mark the developmental process, and not address day-to-day interactions. But, before going any further, it might be useful to recall briefly, for those still unfamiliar with the DMGT, the basic structure of that developmental model.

## Overview of the DMGT

The Differentiated Model of Giftedness and Talent proposes a clear-cut distinction between the concepts of giftedness and talent. The term 'giftedness' designates the possession and use of untrained and spontaneously expressed natural abilities (called aptitudes or gifts) in at least one ability domain, to a degree that places an individual among the top 10% of age peers. By contrast, the term 'talent' designates the superior mastery of systematically developed abilities (or skills) and knowledge in at least one field of human activity, to a degree that places an individual within the top 10% of age peers who are (or have been) active in that field.

### *Gifts (G)*

The DMGT proposes four aptitude domains (see Fig. 1): intellectual, creative, socioaffective, and sensor-

<sup>1</sup> Université du Québec à Montréal, Montreal, Canada.

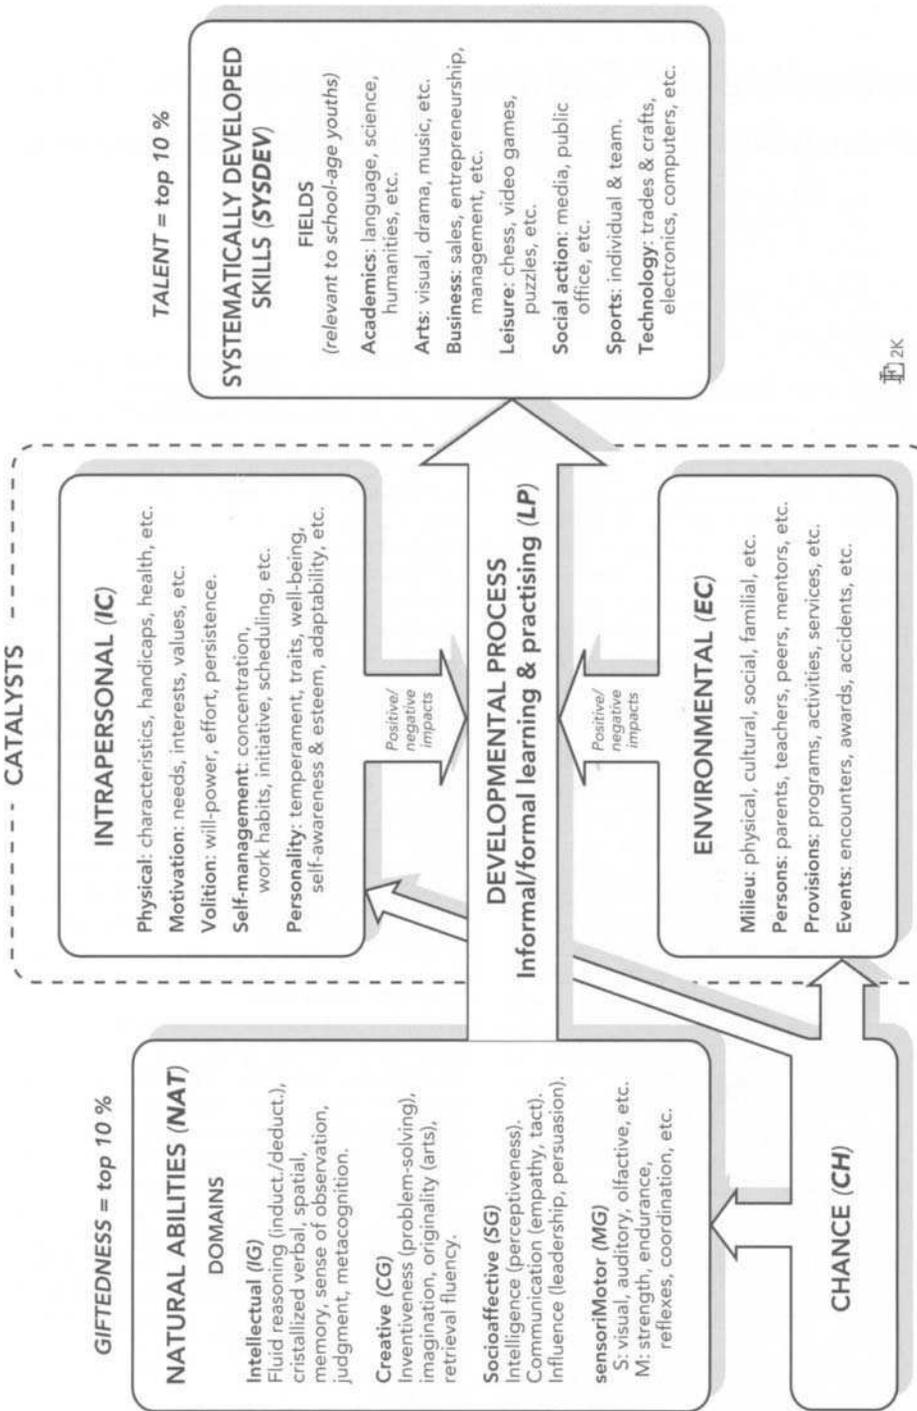

Figure 1. Gagné's differentiated model of giftedness and talent (DMGT.UK.2K)

inmotor. These natural abilities, whose development and level of expression is partially controlled by the individual's genetic endowment, can be observed in every task children are confronted with in the course of their schooling: for instance, the intellectual abilities needed to learn to read, speak a foreign language, or understand new mathematical concepts, the creative abilities needed to solve different kinds of problems and produce original work in science, literature and art, the physical abilities involved in sport, music or woodwork, or the social abilities that children use in their daily interactions with classmates, teachers, and parents. High aptitudes or gifts can be observed more easily and directly in young children because environmental influences and systematic learning have exerted their moderating influence in a limited way only. However, they still show themselves in older children and even in adults through the facility and speed with which individuals acquire new skills in any given field of human activity. The easier or faster the learning process, the greater the natural abilities. It is these high natural abilities that some laypersons call 'talent' or, more appropriately, 'natural talent'.

#### *Talents (T)*

As defined in the DMGT, talents progressively emerge from the transformation of these high aptitudes into the well-trained and systematically developed skills characteristic of a particular field of human activity or performance. These fields can be extremely diverse. Figure 1 shows some of the many talent fields relevant to school-aged youths. A given natural ability can express itself in many different ways, depending on the field of activity adopted by the individual. For example, dexterity, as a natural physical ability, can be modeled into the specific manual skills of a pianist, a painter, or a video-game player. Similarly, intelligence as a natural ability can be modeled into the scientific reasoning of a chemist, the game analysis of a chess player, or the strategic planning of an athlete.

#### *Talent development (LP)*

In this model, natural abilities or aptitudes act as the 'raw materials' or constituent elements of talents. It follows from this relationship that talent necessarily implies the presence of well above average natural abilities; one cannot be talented without first being gifted. The reverse is not true, however. It is possible for well above average natural abilities to remain simply as gifts and not be translated into talents, as witnessed by the well-known phenomenon of academic underachievement among intellectually gifted children. The process of talent development manifests itself when the child or adolescent engages in systematic *learning and practising* (LP); that process can be either formal (e.g. within schools, conservatories, sports leagues or teams) or informal, that is self-taught. The

higher the level of talent sought, the more intensive and long-term these activities will be.

#### *Catalysts (IC and EC)*

This process is facilitated (or hindered) by the action of two types of catalysts; *intrapersonal* (IC) and *environmental* (EC). The intrapersonal catalysts are subdivided into physical and psychological factors, all of them under the partial influence of the genetic endowment. Among the psychological catalysts, motivation and volition play a crucial role in initiating the process of talent development, guiding it and sustaining it through obstacles, boredom, and occasional failure. Self-management gives structure and efficiency to the talent development process, and to other daily activities. Hereditary predispositions to behave in certain ways (temperament), as well as acquired styles of behaviour (e.g. personality traits and disorders), also contribute significantly to support and stimulate, or slow down and even block, talent development. The environment manifests its significant impact in many different ways. The *surroundings* exert their influence both at a macroscopic level (e.g. geographic, demographic, sociological) and in a more microscopic context (size of family, personality and parenting style of caregivers, socio-economic status, and so forth). Many different *persons*, not only parents and teachers but also siblings and peers, may exert a positive or negative influence on the process of talent development. Gifted education programs within or outside the schools belong to the *provisions* category; they are a more systematic form of intervention to foster or hinder the process of talent development. Finally, significant *events* (the death of a parent, winning a prize or award, suffering a major accident or illness) can influence the course of talent development.

#### *Chance (CH)*

Chance is spontaneously associated with the environment (e.g. the 'chance' of being born in a particular family; the 'chance' of the school in which the child is enrolled deciding to develop a program for gifted/talented students; the bad luck of suffering a major accident during athletic training). But, its influence also manifests itself in both the G and IC components of the model through the randomness inherent in the transmission of the genetic endowment.

#### *Prevalence: threshold and levels*

Any definition of normative concepts must specify how subjects differ from the norm and what it means in terms of the prevalence of the population subsumed under the label. In the DMGT, the threshold for both the giftedness and talent concepts is placed at the 90th percentile (approximately 1.3 standard deviations above the mean). In other words, those who belong to approximately the top 10% of the relevant reference group in terms of natural ability (for giftedness) or

achievement (for talent) may receive the relevant label. It must be clearly noted, however, that this generous choice of threshold is counterbalanced by a recognition of levels or degrees of giftedness or talent. Within the top 10% of 'mildly' gifted or talented persons, the DMGT recognizes four progressively more selective subgroups. They are labelled 'moderately' (top 1%), 'highly' (top 1:1,000), 'exceptionally' (top 1:10,000), and 'extremely' (top 1:100,000). As in other fields of special education, the nature of the intervention program that a school develops for gifted or talented students should be influenced by the level of the student's gifts or talents, as well as the domains or fields to which they belong.

### Two Practical Uses of the DMGT

As the preceding overview indicates, the dynamic interactions between the components of the DMGT in the course of talent development remain largely undeveloped. These interactions will be detailed by borrowing heavily from current developmental theories, since talent development is not qualitatively different, in most cases at least, from the acquisition of normal competencies. Until that enrichment is made, I hesitate to use the label 'theory', preferring the more modest one of 'model'. In the words of Keeves (1988), "the model, like the hypotheses which are contained within it, can be built from accumulated evidence, intuition by analogy, or derived from theory" (p. 559). Even in its present model state, the DMGT has a usefulness well beyond its primary goal of demonstrating that the terms giftedness and talent are both essential in our technical lexicon because they allow us to distinguish potential from achievement, natural abilities from systematically developed ones (Gagné, 1999a, 1999c). I will describe below two practical uses of the model, and will illustrate them by analyzing the talent development of a young Vietnamese musician.

#### A 'big picture' reminder

No one will deny that complex human behaviours have a multi-source aetiology, usually involving factors from each of the DMGT's causal components. Yet, that statement is too often given lip service, not only in daily life but in scientific research as well. We are all confronted in the course of our daily life with events that 'demand' an explanation. It can be our own unexpected behavior, that of a family member or a friend; it can also be some behavior observed in a public setting or presented by the media. These causal interpretations have been studied by social scientists under a variety of labels: 'implicit', 'personal', 'naive' or 'lay' theories, or expressions like 'folk psychology', preconceptions, beliefs, and so forth (Pajares, 1992; Goldman, 1993; Calderhead, 1996). Attribution theories (Weiner, 1984) also belong to that large field. These interpretations appear to result from a very spontaneous (inborn?) human propensity to give some

meaning to observed situations. Often called 'mind reading' (O'Hanlon & Hudson, 1995), they can mar human relations when lent wrongly to a friend or spouse's behaviour. What is so typical about most of these attributions and interpretations is their tendency to focus on one, and only one, explanatory factor, to reify that factor, and completely overlook other potential causes for the observed phenomenon. Media people do it when trying to understand the reason behind the latest mass killing; teachers do it when confronted with a student's misbehavior or underachievement. In fact, we all do it in our personal and professional lives. The DMGT can help counterbalance that well-anchored human propensity to simplify causality, by reminding us that what appears to be the most evident cause of a behaviour is probably not the only significant one, and might even not be the most significant one.

Researchers also frequently resort to oversimple interpretations of human behaviour. Because of limited means, most social scientists are forced to observe or manipulate only one or two independent variables. But the pool of potentially influential factors is much larger. Just within our field, causal variables cover the whole spectrum suggested by the DMGT, including: (a) abilities (e.g. IQ, piagetian level, creativity); (b) specific learning processes or strategies (e.g. mathematical operations, problem solving strategies in specific learning situations, metacognitive activities); (c) personal characteristics (e.g. self-efficacy, intrinsic motivation, goal orientation, volition, self-regulation, self-concept); (d) specific pedagogical strategies (e.g. skinnerian reinforcement, individualised instruction, mastery learning, tutoring, co-operative learning); (e) diverse administrative practises (e.g. homogeneous grouping, accelerative enrichment, special schools); or (f) other forms of environmental influences (e.g. peer groups, parental supervision, teachers' characteristics, amount of television viewing, classroom climate). Such a list could be expanded almost without limits. Because they have invested considerable energy in the realisation of their study, researchers have a tendency when finding *statistically* significant results to overestimate the *substantial* significance of these results, especially in the (usual) absence of effect size measures to temper their enthusiasm (Plucker, 1997). Again, if these scholars kept in mind the DMGT's message, namely the multi-source etiology of talent development, they would probably maintain a more relativistic (and modest) attitude toward the significance of their 'pet' variable within the more global explanatory picture.

Besides that natural human propensity to seek meaning, other motives may produce the same blinkered interpretation of talent development. I have especially in mind the tunnelling effect of strongly held theoretical beliefs about the pre-eminence of a particular explanatory variable. Ericsson's conviction that

deliberate practise constitutes the most significant cause of talent emergence is a good example of such beliefs (see Ericsson & Charness, 1994). Even large-scale studies are not exempt from that narrowed explanatory perspective. For instance, Bloom (1985) supervised a series of interviews with twenty top American professionals in six distinct occupational fields (swimming & tennis, neurology & mathematics, music & sculpture). The summary chapter focuses quasi-exclusively on the LP process, and various environmental influences. Bloom's environmental leaning is well known and predates that particular study (e.g. Bloom, 1976). He clearly announced his theoretical position in the Preface of his 1985 book:

The central thesis . . . is the potential equality of most human beings for school learning . . . it leads us to speculate that there must be an enormous potential pool of talent available in the United States. It is likely that some combinations of home, the teachers, the schools, and the society may in large part determine what portions of this potential pool of talent become developed. (1985, p. 5)

That environmental focus is unfortunate in view of the fact that many other causal influences must have been mentioned during the interviews. For instance, in a preliminary publication, Bloom (1982) acknowledged the existence of individual differences in natural abilities:

In homes where other children were also interested in the talent area, the parents sometimes mentioned that one of the other children had even greater 'gifts' than the individual in the sample, but that the other child was not willing to put in the time and effort that the parents or the teacher expected and required. (pp. 512–513)

The potential significance of that causal source was not explored in depth, probably because it conflicted with Bloom's environmentalist tenets. One can only wonder how much information was lost for lack of an analytical framework open enough to encompass all potentially valuable factors of talent emergence. This comment leads us to the second practical use of the DMGT, namely as a classification tool.

#### *An analytical tool*

Researchers can adopt the DMGT's framework of categories and subcategories to classify data. That second practical application, which I have labelled *DMGT-based analysis*, finds usefulness in many different contexts. For example, one could survey the articles of a research journal (or several of them) to identify which types of independent variables appear more frequently in published empirical studies. Thus, longitudinal trends or short-term fads could be observed.

Alternatively, median effect sizes could be obtained within categories and subcategories, making it possible to assess their relative causal impact. Walberg and his colleagues did exactly that type of structured analysis in their ambitious attempt at synthesising the vast literature on school achievement. That literature is relevant to our interests in so far as talent development is but a specific case of the more general theme of competency development over the K–12 schooling process. Walberg and his team surveyed and synthesised close to 3000 empirical studies on the causal influences of student learning (Walberg, 1984). They identified nine significant factors, which they grouped under three headings: *Aptitude* (1. ability; 2. piagetian development; 3. motivation), *Instruction* (4. amount; 5. quality), and *Environment* (6. home; 7. classroom; 8. peers; 9. television). Walberg's model could be considered a coarse analogue of the DMGT. For instance, it confounds abilities and intrapersonal catalysts under the aptitude heading, separates instruction from other environmental inputs, and does not mention clearly the LP process (amount of instruction is dissociated from homework placed in Environment). Still, the goal is the same: bring structure to a large data set.

DMGT-based analysis can be applied to other types of information. Our research team tried it in two different contexts. In one case, we wanted to assess beliefs about the causes of talent emergence. The targets of that research program were educators and students in general education, music, visual arts, and sports. Not only did the DMGT guide the construction of the survey questionnaire, especially the choice of the most relevant causal factors, but it was used as the framework in the data analysis and the presentation of results (Gagné, Blanchard & Bégin, 1999a). DMGT-based analysis was also at the core of a labour-intensive research project recently completed. Forty-two multi-talented adolescents were first identified (Gagné, Neveu, St. Père & Simard, 1997); then, two in-depth interviews were conducted, one with the adolescents themselves and another with at least one parent. We examined the individual's whole life, beginning with the first signs of precocity in their natural abilities, then covering the major events in the development process of each of their talents. The 84 two-hour-long interviews yielded over 1200 pages of transcribed material. Each unit of information (a sentence) was then coded using a category system based on the DMGT (Gagné, 1999b). We found that all relevant information gathered from the interviewees could be codified with high inter-rater reliability, and that no significant information was left uncoded.

If the DMGT offers a useful framework for the study of talent development through interview material, it should apply equally well to biographical data. Because short biographies are easy to find, I decided to use that type of data to illustrate how DMGT-based

analysis helps understand the complex dynamics of talent development. To demonstrate its applicability to any field of talent, I chose the talent development of a young Vietnamese musician.

### DMGT-Based Analysis: An Illustrative Case Study

The descriptive information concerning Dat Nguyen's life story is borrowed from Bartholomew (1997). The story uses as much of her wording as possible, while reducing the length of her excellent article by about half.

---

#### *Dat's story: Act I*

Dat Nguyen was born blind in December 1970 in South Vietnam. Dat's father, an American serviceman, went back to the United States in 1973. Dat's half-sister Yung was born in 1974. Her father, a Vietnamese, disappeared in 1975. When their Vietnamese mother died that same year, they were placed in an orphanage, but it closed after the Communists swept through. The two were taken in by an abusive woman who worked them like slaves. They ran away in 1977 and wandered across the countryside for two years before reaching Ho Chi Minh City (formerly Saigon). There, a man gave them lottery tickets to sell for a small commission. There was little left after they paid for food, however, so they slept on lawns or in alleys. After three years of that life of bare survival, Dat, aged 11, knew he was a triple outcast: blind, Amerasian, and beggar. Yet, even when treated harshly, he would pat his little sister's hand and say to her, "Don't worry, Yung, we will meet some kind people today who will help us".

Anyone reading without any further information this brief overview of Dat's first eleven years of life would find there a perfect scenario for disaster. How could anyone survive such an accumulation of unlucky intrapersonal (innate blindness) and environmental catastrophes (father's departure, second husband's disappearance, mother's death, closing of orphanage, abusive guardian). That series of disasters, succeeding each other within such a short period of time, would burst the top of any stress scale! Indeed, in most North-American school settings, just one of these events would be judged traumatic enough by itself to 'explain' a child's personal or social misadaptation. The fact that this 6-year old blind boy decided to run away from their abusive guardian, not alone but with his half-sister, demonstrates extremely precocious maturity and inner strength. The odds were so heavily against them, and yet he dared make that move. He was probably still too young to understand the negative impact of his mixed blood in the aftermath of the war, but no doubt

that it was pointed out to him regularly by their guardian, and by other people they met. The fact that both children survived two years of wandering plus three more of barest survival in Ho Chi Minh City implies above average resourcefulness, a form of practical intelligence (Sternberg & Wagner, 1986) that could fit in either the DMGT's cognitive or creative domains. During that period, the text mentions just one significant positive environmental input: being given lottery tickets to sell. Still, at that point in time, in fact at the midpoint of the period covered by this story, nothing could lead anyone to expect that an exceptional talent would ever emerge from such a terrible beginning. And yet, the miracle happened.

---

#### *Dat's Story: Final Act*

Some time in 1993, Professor David Grimes, head of the Fullerton classical-guitar program at Cal State University, auditioned all the newcomers. At five-foot-one and 95 pounds, 22-year-old Dat Nguyen looked like a child. He sat down to play, caressing his cheap guitar while coaxing extraordinary beauty from it. Grimes was astounded: Dat's technique was a bit raw, but his phrasing showed an intimate understanding of the material. What grabbed Grimes most was the power, the emotion. Grimes soon learned that he had to make only minimal accommodations for Dat's blindness, because he had a most extraordinary ear for music; he could play almost anything, note for note, after hearing it once. Dat practised up to eight hours a day, often getting up before dawn to play, muffling his guitar with a towel so as not to disturb the neighbours.

One day in October 1994, Grimes told his students he had some applications for the Southern California American String Teachers Association competition. He cautioned his students against setting their goals on winning; there would be strong competitors from other top music schools in California. Yet, Dat won easily and went on to win the state-wide competition. In Vietnam, music had given him the strength to survive. In America, it had brought him an acceptance he might never have known. He was, it seemed at that moment, a very lucky young man.

---

I skipped on purpose (for dramatic effect!) all intervening events to show immediately the endpoint of Dat's story: the confirmation of his exceptional talent as a classical guitarist. As unbelievable as it may seem, Dat went, in just eleven more years, from beggar and ticket peddler to undergraduate student in classical guitar at a U. S. university. I can imagine many readers itching to look immediately at the next framed text to see what happened in that time interval to bring about such a miracle. Please bear with me a little; this short

finale deserves at least two comments. First, the DMGT's definition of talent and its system of prevalence levels are well illustrated. Recall that talent is defined strictly as high level performance, no more no less. Being accepted in a very selective university program no doubt places any music student well within the talent zone, probably within the top 1% of the appropriate reference group, namely all those who have attempted to learn to play the guitar, whether they kept at it or abandoned at some point (Gagné, 1993). Moreover, among all these university students in music, the odds of winning a regional competition would certainly not exceed 10%, easily placing such a winner one rung higher (1:1,000) on my metric-based talent ladder (Gagné, 1998). Finally, assuming that the state-level competition included at least ten participants, winning it would mean acceding to the next higher level. In other words, these achievements probably place Dat among exceptionally talented (1:10,000) guitarists. And that remarkable success was achieved in just eleven years.

Second, the text mentions one potential cause for that achievement, namely outstanding natural abilities: (a) the socio-affective ability to understand intimately the emotional meaning of a piece of music and express it with deep feelings, and (b) the cognitive ability to memorise almost any musical piece, note for note, after hearing it just once. Such a feat is beyond reach for the quasi-totality of professional musicians, yet extremely useful to a blind performer. Most people would probably conclude that this mnemonic ability was progressively developed with much deliberate practise because of Dat's blindness. Does not the need create the instrument? I will not deny that the advantage of such an ability in his case acted as an incentive to pursue the acquisition of that skill, and that much practise was involved. But, any professional musician knows how extremely difficult it is to develop such an extraordinary capacity, especially when one cannot see the musical score. It would be interesting to survey blind professional musicians and ask them to what extent they have mastered that instant mnemonic recording, a feat that compares, in its extreme rarity, to the better analysed phenomenon of eidetic memory (Haber & Haber, 1988). But, let us now look at the most significant events that bridge the first and final acts of Dat's story.

my favourite thing." "You've got that drum riff down like a pro. How would you like to try a real set of drums?" The man led him to his house, handed Dat drumsticks and gave him a few instructions. Dat hammered away, amazed at the sounds booming through the room. Soon he was wildly drumming on cymbals, and the snare and bass drums. He played for hours before realising that he might have overstayed his welcome. But as he apologised, the man said: "Overstayed? You were just getting started. Come back tomorrow." So, he returned the following day, and almost every day after that. Within a few months, he was playing with the rock band.

One day when Dat was 12, another lottery customer suggested he meet Mr. Truong, one of Saigon's finest classical music teachers. "He loves to nurture young musicians," the customer explained, "and he is also blind." Truong listened to Dat play the drums. "You have talent," he said as Dat finished. "You will be my student." Truong explained that he never took money from a blind student. What's more, he would give Dat and his sister the money they needed to live. In the months that followed, he introduced Dat to the piano and several stringed instruments, and taught him to read Braille. As the instruments resonated under the boy's sensitive fingers, the old man beamed like a proud father.

One Sunday morning in 1988, Dat, now 17, tuned Truong's radio to the classical music hour, featuring a concert by the Spanish guitarist Segovia. Dat had never heard anything so beautiful and complex. In an instant he knew he had to learn to play the guitar like that. Dat bought a used guitar, and Truong found a music book in his Braille library. Dat played for hours at a time, the guitar freeing him to express himself as never before.

That same year, an Amerasian girl told Dat she was going to the United States under a new program that brought Amerasian children to America. "Why don't you apply?" she suggested. In January 1991, sponsored by a Vietnamese American, Dat and Yung arrived at their new home in Orange County, CA. Dat attended Anaheim High School for two years. He learned so quickly that his teachers encouraged him to enrol at Cal State Fullerton. And there he met David Grimes.

---

#### *Dat's Story Act II: The Intervening Events*

Dat's favourite place to sell tickets was the local barbershop. One of the things he liked best about the store was that its radio blared American songs. As he sang with the music, he pounded the back of a barber chair. One day, a local bandleader noticed him and said, "you like music?" Dat nodded: "It's

---

#### **Talent Development: A Complex Choreography**

As I have observed time and again when presenting that story, most people, professional educators and laypersons alike, tend to interpret the second half of Dat's life, the lifespan covered by Bartholomew's (1997) article, as the mirror image of the first half. To the same degree that the first eleven years saw an accumulation of bad luck, the second half was marked

by an unending series of lucky environmental inputs. The series began with the chance encounter of the local bandleader; it continued one year later when another lottery customer directed Dat to Mr. Truong. The next major lucky event was the chance tune-in to Segovia's concert, soon followed by the chance meeting of an Amerasian girl who recommended to Dat that he apply for a special U. S. immigration program which targeted Amerasian Vietnamese children. Then, Dat was discovered by a Vietnamese American, who sponsored his (and his sister's) immigration to the U. S. Finally, his high school teachers, as well as Professor Grimes, paved the way for his admission and subsequent achievements in Cal State Fullerton's classical guitar program. So, as Dat himself reflects, is he just a lucky young man? A closer look at this short biography, aided by DMGT-based analysis, will reveal a much more complex picture of successive interactions between 'events' and personal characteristics that cover all five causal components of the DMGT.

Before examining the role played by each factor, the following comment must be made. The DMGT is a *talent* development model; it illustrates a process whose goal or endpoint is the achievement of talented performances. The choice of that particular goal was predetermined by this author's desire to better differentiate the concepts of giftedness and talent. And the best way, in my view, to operate that differentiation was to define them respectively as the beginning and endpoint of a developmental process through which high natural abilities (gifts) progressively give rise to high level systematically developed skills (talents) in a specific field of human activity. This comment introduces a *relevance rule*, which states that only those elements that have a direct, immediate, and significant impact—positive or negative—on the attainment of the sought goal, in this case musical talent, should be included in any causal component of the model. For example, I purposely avoided using the EC label for all the environmentally induced catastrophes suffered by Dat and his little sister during the first ten years of their life; similarly, I did not apply the IC label to extremely precocious indices of Dat's strength of character, and unfaltering optimism. Thus, retrospective information would be brought in only as supporting evidence for any element directly recognised as a causal factor in Dat's *musical* talent development. Let us now proceed to the separate examination of each causal component.

#### *Natural abilities*

Just as bringing an animal to the trough does not ensure its drinking, offering supportive environmental conditions does not guarantee that excellence will automatically ensue. The first question to ask is: "Why was Dat noticed by the bandleader, adopted by Mr. Truong, pushed toward Cal State by his high school teachers, and singled out by Professor Grimes? Are these environmental inputs pure chance events, the

result of proactive social gestures that just reflect human nature at its best? In fact, the text shows clearly that these individuals did react to behaviours they interpreted as signs of exceptional potential. The bandleader saw the 'drum riff' of a pro; Mr. Truong saw that he had 'talent', which meant without doubt 'natural' talent, or giftedness for music; the teachers also saw intellectual giftedness because of his rapid progress in spite of his visual handicap and past schooling history; Professor Grimes noticed Dat's exceptional emotional sensitivity and auditory memory. It is my conviction that *none* of these people's reactions and proposals would have ever happened if they had not observed at the outset exceptional natural abilities. In other words, each of these events was triggered by Dat's behaviour. I am not saying that there was no chance in any of them; indeed, there was chance on every occasion. But, that chance was activated by Dat's exceptional natural gifts. I will come back to the chance factor later.

And the giftedness observed at first sight by the bandleader, Mr. Truong, and Professor Grimes was subsequently confirmed through Dat's ease and speed of learning, the DMGT's best indicator of giftedness in the absence of aptitude testing. He learned so fast to play the drums, especially in spite of his handicap and the fact that this instrument is probably the most visually dependent of all musical instruments, that he was playing with the band within six months. Similarly, as a student of Mr. Truong, Dat learned in just a few months to play many instruments and read Braille; Dat's talent developed in fact so rapidly that Mr. Truong 'beamed like a proud father'. And again, it was his ease and speed of learning that brought him to the attention of his teachers at Anaheim High School. Note that Dat Nguyen received no formal schooling until he was 14 years-old (Dat Nguyen, personal communication, September 22, 1999). Even though the article does not mention it, we might surmise that learning Braille opened the door not only to written music but also to some academic knowledge. Even with that huge delay in formal schooling and a handicap that severely limits the educational accomplishments of most children affected (Blanchard, 1997), Dat obtained his high school diploma when he was just a few years older than the average American student. Finally, Dat only began learning the classical guitar when he was 17 years-old, attaining his high level of excellence with just five or six years of systematic LP, most of them self-taught (see Postscript).

#### *Intrapersonal catalysts*

The IC component may take different forms, of which only a few illustrative examples are shown in Fig. 1. Let us look first at the motivational aspects. They can be subdivided into two parts: a directional or goal component (e.g. drives, needs, interests) and a sustaining or volitional component (Corno, 1993) that works

at overcoming any intervening obstacles (digressions, temptations, boredom, accidents) so that the chosen goal will be attained. The text mentions two 'directional' elements: (a) Dat's answer to the bandleader about music being his favourite thing, and (b) his 'love at first sight' (a double metaphor!) for the classical guitar as he listens to Segovia's concert. In this second instance, the term passion would be an appropriate label. The volitional component can be easily confounded with the LP process, since will power and persistence are commonly observed through the amount of work done, the intensity of the learning and practise. But volition implies effort in the face of difficulties; thus, amount of LP is not by itself a 'pure' indicator of volitional strength. For instance, in his first encounter with real drums, Dat played for hours; in that case it is just a sign of intense interest. Indeed, Bartholomew's (1997) article never mentions directly that volitional component. But it is always there, in filigree, through mentions of years upon years of bare survival, as well as long hours of music practise, day after day, week after week. This component brings to mind Sir Francis Galton's (1869/1962) often-cited comment:

By natural ability, I mean those qualities of intellect and disposition, which urge and qualify a man to perform acts that lead to reputation. I do not mean capacity without zeal, nor zeal without capacity, nor even a combination of both of them, without an adequate power of doing a great deal of very laborious work. (p. 77)

A DMGT-based analysis of that quote will associate capacity with giftedness, disposition with temperament (IC), zeal with intrinsic motivation (interest, passion), and the power of laborious work with the volitional aspect of motivation. In Galton's terms, reputation (talent, eminence) will emerge from proper qualifications (high capacities, gifts), urges and zeal (needs, passions), as well as the power for laborious work (volition, perseverance). It is interesting that little importance is given to environmental influences.

The intrapersonal component of the DMGT includes many more 'ingredients' besides motivational constructs. Temperament and personality traits constitute a major subdivision, as well as personal beliefs (e.g. self-perceptions, implicit theories, attitudes, values). Bartholomew's (1997) short article does not explore that area in much detail. The few elements that stand out were mentioned earlier and predate Dat's musical talent development; so they cannot be included. But, to better illustrate the contents of the IC component, I could add resilience (O'Connell Higgins, 1994). Even after years of begging, he maintained an unflagging optimism, as witnessed by his comment to his little

sister when treated harshly: "Don't worry, Yung, we will meet some kind people today who will help us."

#### *Environmental catalysts*

Environmental catalysts are no doubt the most visible of all five causal factors. We are constantly surrounded by stimuli, and one of the major roles of our lower brain is to monitor that input and bring to consciousness only the most significant sensory information. That selection process needs to be mentioned because it points to a major difference between environmental *inputs* and environmental *catalysts*. Webster's dictionary proposes the following broad definition of a catalyst: "any agent that provokes significant change" (1991, p. 214). And there lies the difficulty: determining the degree of causal impact of any environmental stimulus. It is a well-known psychological fact that individuals do not react similarly, either cognitively or affectively, to any stimulation; indeed, studies in behavioural genetics have shown that, contrary to common-sense beliefs, familial environmental influences contribute much more to sibling *disparities* than to their similarities (Plomin, DeFries & McClearn, 1990). Moreover, according to the relevance rule stated earlier, these environmental inputs must affect the target phenomenon, here Dat's musical talent development. For instance, very good parents may have played a significant role in the development of their child's personality; yet, their role with regard to that child's talent development could have been much more unobtrusive (except maybe paying the bills!). With these caveats in mind, let us examine the text. In the case of Dat's first eleven years in this world, two opposite points of view could be defended. Some could argue that because the dramatic events preceded the beginning of Dat's musical talent development, they cannot be properly introduced as catalysts: catalysts play their role *during* the chemical reaction, don't they? Others might point out that if Dat had benefited from a more normal environment during his youth he would have encountered much earlier the occasions or favourable circumstances that often launch the systematic development of new skills; consequently, these events hindered the process by retarding its beginning. To be honest, I would feel comfortable with either of these two positions. Still, the first clearly relevant EC mentioned in Bartholomew's (1997) article is the bandleader inviting Dat to come and try his drums.

It is not surprising that all the major EC influences are significant persons: the bandleader, Mr. Truong, the Amerasian girl, the Vietnamese-American sponsor, a few Anaheim high school teachers, and Professor Grimes. No doubt that humans are more easily conceived as significant causal influences than inanimate objects. Some of these persons played their catalytic role over a long period of time (e.g. bandleader, Truong, Grimes), whereas others (e.g. the

lottery customer who guided Dat to Mr. Truong, the Amerasian girl) just gave a nudge, albeit a very important one, in the right direction. But other EC categories appear in the text. For instance, even though it is not a direct musical provision, I would place the immigration program in the Provisions category. It is very relevant to Dat's talent development, because it allowed him to come to the U. S. and maximize his chances of finding a suitable environment to pursue his learning of the classical guitar. I would include in the Events category tuning in by chance to Segovia's concert; that event made Dat discover in himself the powerful addictive impact of the extremely refined and complex 'sound' of the classical guitar. That was one of those rare 'crystallising experiences' first described by Walters & Gardner (1986). Yet, we must ask ourselves what was more important for Dat's musical talent development: the guitar concert (EC) or Dat's special emotional sensitivity to that instrument or music (IC)? Thousands of persons probably listened to that particular concert on the radio, but only one among them was moved to the point of completely reorienting his life and career plans to include that musical instrument. I personally believe that such an impact says much more about Dat's emotional sensitivity than about the guitar's power of attraction. Granted that the event had to take place for that sensitivity to be aroused; but chances are that, because he was actively involved in music, Dat Nguyen would have encountered sooner or later that particular musical form.

Two additional comments. First, can the classical guitar program at Cal State Fullerton be considered a significant EC within the Provisions category? I am still debating that point. My present position leans toward a more selective interpretation of the relevance rule: a program should have a *unique* impact on the talent development of a person to receive the EC label, an impact that no other similar program could have had. In other words, because a college-level music program is a necessary constituent in the training of any professional musician, and so cannot serve to differentiate the more talented from the less talented ones, I would tend to include it instead within the LP component. I would argue similarly that any regular K–12 curriculum or school environment would not be considered an EC unless something special or unique existed in that program that contributed *directly and significantly* to a person's talent development. Second, many people believe in the 'formative' role of adversity, namely that difficult life situations during youth toughen individuals and prepare them to better confront the challenges of adult life. Adversity as a character builder is a very strange hypothesis in view of the overwhelming literature on the importance of an early supportive family environment to ensure normal development. I do not believe that adversities 'build' character; what they do is give those who already have some inborn strength of character, as I believe Dat

possesses, an excellent occasion to demonstrate that strength. Very few 6 year-old children, even with perfect eyesight, would have dared take Dat's decision to flee with his young sister; indeed, most would not even have thought of it.

#### *The LP process*

As a causal factor, the LP component plays a special role in the DMGT: it corresponds to the *process* through which high natural abilities (gifts) are transformed into the specific skills that characterise a particular field of talent. No one will deny that this component is crucial in talent development: no skills have yet been discovered that blossom overnight! One needs only to compare novices with experts to realise the huge amount of knowledge and skill generated by months and years of LP. From that macroscopic perspective, *mean* differences in performance will be evident between beginners and more advanced students (artists, athletes, etc.). On that point I totally agree with Ericsson and Charness's (1994) position: macroscopically speaking, practise does make perfect. But the real question is: "Does deliberate practise play the most important role in Dat's (or anyone's) success, as Ericsson and Charness would argue?" I strongly disagree. When we control the amount of LP (e.g. students in the same grade), we observe that yearly average improvements in performance are accompanied by large standard deviations; in other words, significant incremental differences in knowledge from one school grade to the next are accompanied by large *within-grade* differences in academic achievement (Biemiller, 1993; Schulz & Nicewander, 1997). These residual individual differences reflect, among other things (e.g. quality of instruction, motivation), disparities in *pace of learning*; indeed, some of the best students (performers, athletes) will not be practising more, sometimes even less, than more average peers. I observed that exact phenomenon in music in the results of a study by Sloboda & Howe (1991) with students in a special music school. The top-achieving half of their sample practised on average *a third less*; yet, their level of achievement was *twice as advanced* as that of students occupying the bottom half (Gagné, 1999d). Moreover, studies of the impact of homework on school achievement have shown only modest results (Walberg, 1984). In summary, while LP is no doubt an essential component of the talent development process, I believe that it accounts for only a modest percentage of the large individual differences in achievement observed among persons enrolled in a similar LP program.

#### *Chance*

Bartholomew (1997) states toward the end of her article that Dat Nguyen perceived himself to be "a very lucky young man." Is this whole story a poem to chance? I am not aware of any studies that have tried to

assess individual differences in the role of chance over the course of people's lives. So, it is not possible to determine to what extent, normatively speaking, chance played a bigger role in Dat's life than it did for other individuals. One would also need to qualify the type of chance observed. Austin (1978) described four levels of chance events, differentiated by the degree of activity of the person, from passive 'blind luck' to the focused exploratory behaviour of the researcher. According to Austin, both the activity level and its focus increase the chances of fate showing its fickle finger. All these considerations make it difficult to circumscribe the exact role of chance in Dat's life.

The chance factor was borrowed from Tannenbaum's (1983) model, and first introduced in the DMGT to stress the randomness of many life events (being discovered by a mentor, accidents, etc.). In the first edition of this handbook (Gagné, 1993), chance was present as a fifth element among the environmental catalysts. But, it soon became clear that chance influences all the environmental catalysts (e.g. the socio-economic status of a child's family, the quality of the parenting, the existence of talent development programs in the neighbourhood school, and so forth). That is why it could not appear as one element within a list of ECs. Moreover, chance manifests itself in another major event, namely the transmission of hereditary characteristics; there are few human phenomena more dependent on chance than the specific mix of genes resulting from the random meeting of a particular ovum and one among billions of spermatozooids. In that respect, Tannenbaum cites Atkinson's (1978) belief that all human accomplishments can be ascribed to "two crucial rolls of the dice over which no individual exerts any personal control. These are the accidents of birth and background" (Tannenbaum, 1983, p. 221). Atkinson's 'accident of birth' stresses the role of chance outside of ECs, especially in the giftedness and IC components. If Dat is a 'lucky young man', it is first and foremost because of the exceptional gifts received from Nature. We could add to these natural abilities the strong temperament, again a gift of Nature, that allowed him to survive through an incredible series of traumatic events, and, finally, the lucky encounters that completely reoriented his life toward the development of an exceptional musical talent. In brief, as shown in Fig. 1, there is some degree of chance in all the causal components of the model, except maybe the LP process.

#### Summary

The above analysis of Dat Nguyen's musical talent development illustrates how his exceptional talent as a classical guitarist progressively emerged from complex interactions between all the causal factors that comprise the DMGT; and I would be hard-pressed to single out any of them as having played an overwhelming role. The analysis demonstrates the importance of

Dat's high natural abilities (G), without which none of the chance (CH) events (EC) that launched his musical career would ever have materialised. At the same time, the significant individuals mentioned (EC) were essential to his talent development, since without their support Dat would probably have never discovered how musically gifted he was nor how strong was his attraction for that field. Moreover, without his passionate interest for music (IC), he would not have followed up on the bandleader's invitation to learn the drums, nor taken up Mr. Truong's invitation to become his music teacher, nor switched instantaneously to the classical guitar after listening to a Segovia concert. The hundreds of hours of practise (LP) were also essential to develop Dat's musical skills, but his giftedness allowed him to progress at a much faster pace than the vast majority of music students. Also, no doubt that a strong will power (IC) helped him stay on course during the difficult moments of his talent development process. In summary, it confirms that all the causal factors were *necessary*—in the statistical sense—to produce these exceptional achievements, and that none of them was by itself *sufficient*—again in the statistical sense—to bring about Dat's exceptional musical talent. This essential-but-not-sufficient character of each of the DMGT's components as contributors to Dat's exceptional talent, as well as their constant interplay over time, exemplifies my 'complex choreography' metaphor to describe the talent development process.

#### Conclusion

I have tried to describe in this text two practical uses of the Differentiated Model of Giftedness and Talent (DMGT). One of them is a cartographic representation of the major groups of determinants of talent development and, consequently, a constant reminder of the 'big picture', namely the rich diversity of potential causes of talent emergence. But, in my view, the DMGT should be most useful as an analytical tool, a system of categories and subcategories enabling professionals and scholars to classify developmental information gathered through interviews, biographies, surveys, and so forth. There is still much to discover about the dynamics of talent development, about the relative importance of various causal factors, or the most common causal direction when two factors influence each other over time in a bi-directional causal spiral, or the change in importance of these factors as individuals move from youthful precocity to mature talent. I am convinced that DMGT-based analysis could help researchers in the field bring better understanding to these still coarsely charted waters.

---

#### Postscript

As I was completing this manuscript in the fall of 1999, I decided to contact Dat Nguyen. We talked a

few times on the phone. I sent him a tape of the manuscript, asking for his help to ascertain the correctness of the information, and the face validity of my analysis. He acknowledged that my outside analysis had given him new insights on his past. He confirmed two points about which I had lingering doubts. First, the Segovia concert was really a crystallising experience—as defined by Walters & Gardner, 1986—a falling in love with the classical guitar as sudden and intense as Bartholomew had described. Second, Dat stated that his instant memory for music and lyrics goes back as far as he can remember, even before he began studying music formally. That gift has improved over the years to a point where he can now easily memorise 8-note chords, as well as whole clusters played in rapid succession. He mentioned having tried to teach that ability to young musicians, so far without success. That failure strengthened his conviction that there was an inborn component to that ability. He also has perfect pitch; that ability goes back to his first music lessons, and is judged by him to be inborn to some degree. Finally, Dat pointed out that he began studying the classical guitar for a year with a professional teacher while still living in Ho Chi Minh City. But, during the next four years, as he moved from Vietnam to the U.S. and completed high school, he had no music teacher. Self-teaching alone brought his competence to a level high enough to be admitted to Fullerton. That makes his achievements even more remarkable.

Since the Bartholomew article, Dat Nguyen's career as a classical guitarist has progressed. In 1996, he was chosen to represent his state in a national competition of classical musicians called the Panasonic Young Soloist Award. The only guitarist among the 50 participants, he reached the finals (3 participants). Last spring, aged 28, Dat completed his bachelor's degree in guitar performance at Fullerton. In October 1999, he played against 80 classical guitarists from seven countries in a world-level competition organised by the Guitar Foundation of America, and held in Charleston, SC. Unfortunately, he did not attain the finals (12 participants), but enjoyed tremendously that high-level experience. Dat has decided to take a sabbatical leave for a year or two to devote more time to performing and composing. Not only does he play the classical guitar repertoire, but he also loves jazz, flamenco, and Vietnamese music. To make ends meet, he performs regularly, either alone or with his own guitar quartet. For at least the last twelve years, he has been writing songs and composing instrumental music. He hopes to record some of his work in the near future. Dat plans to enroll within a year or two in a graduate music program.

# New Conceptions and Research Approaches to Creativity: Implications of a Systems Perspective for Creativity in Education

Mihaly Csikszentmihalyi<sup>1</sup> and Rustin Wolfe<sup>2</sup>

## Introduction

At the beginning of the third millennium, the importance of creativity becomes ever more critical. Age-old problems, such as coexistence on an increasingly interdependent planet, need new solutions for our species to survive. And the unintended results of the creativity of past centuries require even more creativity to be resolved, as we must learn to cope with the aftermath of previous successes, such as increasing population density and chemical pollution.

For several millions of years young people have learned how to adapt successfully by learning practical skills from their elders. But during the last few generations, they have become dependent on schools for acquiring the information necessary to cope with their environment. Thus we might expect that creativity, inasmuch as it can be taught, would be learned and practiced in schools. Yet—with notable exceptions—schools seem to be inimical to the development of creativity. For instance, Getzels and Jackson (1962) found that students who scored high on creativity tests were generally disliked by teachers, who preferred students who were highly intelligent but less creative.

In a recent study of 91 exceptionally creative writers, musicians, businessmen, and Nobel-prize winning scientists, these individuals almost never mentioned their elementary or secondary schools as having helped them to develop the interest and expertise that led to their later accomplishments. Almost every person could mention one or two very influential teachers, but classroom activities as such were generally remembered as boring and repressive (Csikszentmihalyi, 1996). Is this a necessary feature of institutionalized mass education? Or are there ways to make schools more friendly to the development of creativity? Before attempting to deal with such questions, it will be useful

to present our perspective on what creativity consists of.

## A Definition of Creativity

Creativity can be defined as an idea or product that is original, valued, and implemented. Traditionally creativity has been viewed as a mental process, as the insight of an individual genius. Psychologists have assumed that creativity consists of breaking down conceptual paradigms as they are solving problems. But where do paradigms come from? Where do problems come from? On second thought, it becomes obvious that creativity cannot exist in a vacuum; new is relative to old. Without norms there can be no variation; without standards there can be no excellence. Such obvious considerations should alert us to the fact that whatever individual mental process is involved in creativity, it must be one that takes place in a context of previous cultural and social achievements, and is inseparable from them.

While originality refers to any new idea or product, creativity is a subset of originality that is also valuable (Fig. 1). But how do we know whether or not an original solution is worth implementing? From where

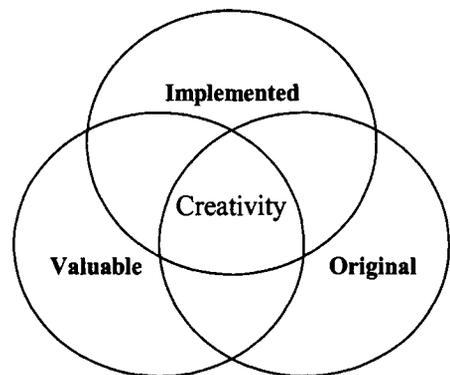

Figure 1. General Model of Creativity.

<sup>1</sup> Claremont Graduate University and The University of Chicago, USA. E-mail: miska@cgu.edu

<sup>2</sup> Claremont Graduate University and The University of Chicago, USA. E-mail: rustw@ccp.uchicago.edu

do we get our internal standards? Who is to judge what is valuable? These questions point at the importance of a supportive and evaluative context beyond the individual. Most definitions of creativity also stipulate that an idea must be implemented before its success can be evaluated. Implementation, in turn, requires inputs and resources that are usually beyond the individual's control.

While individual originality clearly plays a necessary role in the creative process, it is only one part. In this chapter, we will propose that an intrapsychic approach cannot do justice to the complex phenomenon of creativity, which is as much cultural and social as it is a psychological event. To develop this perspective, we will use a 'systems' model of the creative process that takes into account its essential features. Later, we shall consider what role educational institutions can play in fostering creativity according to the systems model.

### The Systems Model of Creativity

Creativity research in recent years has been increasingly informed by a systems perspective. Starting with the observations of Morris Stein (Stein, 1953, 1963), and the extensive data presented by Dean Simonton showing the influence of economic, political, and social events on the rates of creative production (Simonton, 1988, 1990), it has become increasingly clear that variables external to the individual must be taken into account if one wishes to explain why, when, and where new ideas or products arise from and become established in a culture (Gruber, 1988; Harrington, 1990). Magyari-Beck (1988) has gone so far as to suggest that because of its complexity, creativity needs a new discipline of 'creatology' in order to be thoroughly understood.

The systems approach developed here has been described before, and applied to historical and anecdotal examples, as well as to data collected to answer a variety of different questions (Csikszentmihalyi, 1988b, 1990b, 1996, 1999; Csikszentmihalyi, Rathunde & Whalen, 1993; Feldman, Csikszentmihalyi & Gardner, 1994; Csikszentmihalyi & Sawyer, 1995).

#### *Why is a Systems Approach Necessary?*

When the senior author started studying creativity over 30 years ago, like most psychologists he was convinced that it consisted of a purely intrapsychic process. He assumed that one could understand creativity with reference to the thought processes, emotions, and motivations of individuals who produced novelty. But each year the task became more frustrating. In a longitudinal study of artists, for instance, it was observed that some of the potentially most creative persons stopped doing art and pursued ordinary occupations, while others who seemed to lack creative personal attributes persevered and eventually produced works of art that were hailed as important creative

achievements (Getzels & Csikszentmihalyi, 1976; Csikszentmihalyi & Getzels, 1988; Csikszentmihalyi, 1990b). To use just a single example, young women in art school showed as much, or more creative potential than their male colleagues. Yet twenty years later, not one of the cohort of women had achieved outstanding recognition, whereas several in the cohort of men did.

Psychologists have always realized that good new ideas do not automatically translate into accepted creative products. Confronted with this knowledge, one of two strategies can be adopted. The first was articulated by Abraham Maslow and involves denying the importance of public recognition (Maslow, 1963). In his opinion it is not the outcome of the process that counts, but the process itself. According to this perspective a person who re-invents Einstein's formula for relativity is as creative as Einstein was. A child who sees the world with fresh eyes is creative; it is the quality of the subjective experience that determines whether a person is creative, not the judgment of the world. While we believe that the quality of subjective experience is the most important dimension of personal life, we do not believe that creativity can be assessed with reference to it. In order to be studied by the interpersonally validated tools of science, creativity must refer to a process that results in an idea or product that is recognized and adopted by others. Originality, freshness of perceptions, divergent thinking ability are all well and good in their own right, as desirable personal traits. But without some form of public recognition they do not constitute creativity. In fact, one might argue that such traits are not even necessary for creative accomplishment.

In practice, creativity research has always recognized this fact. Creativity tests, for instance, ask children to respond to divergent thinking tasks, or to produce stories, or designs with colored tiles. The results are assessed by judges or raters who weigh the originality of the responses. The underlying assumption is that an objective quality called 'creativity' is revealed in the products, and that judges and raters can recognize it. But we know that expert judges do not possess an external, objective standard by which to evaluate 'creative' responses. Their judgments rely on past experience, training, cultural biases, current trends, personal values, idiosyncratic preferences. Thus whether an idea or product is creative or not does not depend on its own qualities, but on the effect it is able to produce in others who are exposed to it. Therefore it follows that what we call creativity is a phenomenon that is constructed through an interaction between producer and audience. Creativity is not produced by single individuals, but by social systems making judgments about individuals' products.

A second strategy that has been used to accommodate the fact that social judgments are so central to creativity is not to deny their importance, but to separate the process of *creativity* from that of

*persuasion*, and then claim that both are necessary for a creative idea or product to be accepted (Simonton, 1988, 1991, 1994). However, this stratagem does not resolve the epistemological problem. For if you cannot persuade the world that you had a creative idea, how do we know that you actually had it? And if you do persuade others, then of course you will be recognized as creative. Therefore it is impossible to separate creativity from persuasion; the two stand or fall together. The impossibility is not only methodological, but epistemological as well, and probably ontological. In other words, if by creativity we mean *the ability to add something new to the culture*, then it is impossible to even think of it as separate from persuasion.

Of course, one might disagree with this definition of creativity. Some will prefer to define it as an intrapsychic process, as an ineffable experience, as a subjective event that need not leave any objective trace. But a definition of creativity that aspires to objectivity, and therefore requires an inter-subjective dimension, will have to recognize the fact that the audience is as important to its constitution as the individual to whom it is credited.

Thus, starting from a strictly individual perspective on creativity, we were forced to adopt a view that encompasses the environment in which the individual operates. This environment has two salient aspects: A cultural, or symbolic aspect which here is called the *domain*; and a social aspect called the *field*. Creativity is a process that can be observed only at the intersection where individuals, domains, and fields interact.

#### *An Outline of the Systems Model*

In the *Origin of Species*, Charles Darwin described the process by which nature ‘invents.’ To paraphrase:

“Nature’s mechanism of invention lies in the process of natural selection. Unpacked into its details, natural selection depends on three subprocesses: (1) genetic variation; (2) selection of adaptive results via the test of survival and reproduction; (3) inheritance of the adaptive results. According to the Darwinian perspective, this trio of subprocesses, over millennia, leads to the emergence of new species” (Perkins, 1988, p. 367).

Describing biological evolution may, at first, seem an odd way to present a model of creativity (Fig. 2), but the process of evolution at the level of species is analogous to the creativity at the level of cultural traits. Biological evolution occurs when an individual organism produces a genetic *variation* that is *selected* by the environment and *transmitted* to the next generation (see Campbell, 1976; Mayr, 1982; Csikszentmihalyi, 1993). In biological evolution, it makes no sense to say that a beneficial step was the result of a particular genetic mutation alone, without taking into account environmental conditions. For instance, a genetic

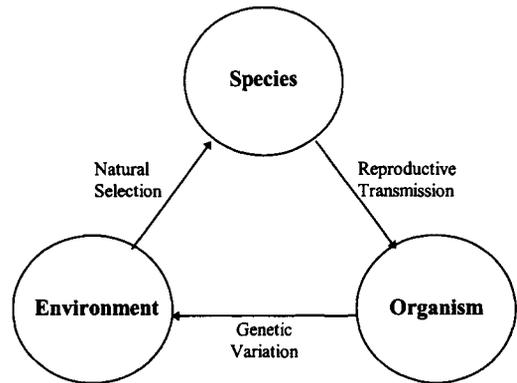

Figure 2. Model of Biological Evolution.

change that improved the size or taste of corn would be useless if at the same time it made the corn more vulnerable to drought, or to disease. Moreover, a genetic mutation that cannot be transmitted to the next generation is also useless from the point of view of evolution.

According to Sterman, this paradigm has now been widely accepted in the social sciences as a model of learning in general:

“John Dewey . . . recognized the feedback-loop character of learning around the turn of the century when he described learning as an iterative cycle of invention [variation], observation, reflection [selection], and action [transmission] (Schön, 1992). Explicit feedback accounts of behavior and learning have now permeated most of the social sciences. Learning as an explicit feedback process has even appeared in practical management tools such as Total Quality Management, where the so-called Shewhart-Deming PDCA cycle (Plan-Do-Check-Act) lies at the heart of the improvement process in TQM (Shewhart, 1939; Walton, 1986; Shiba et al., 1993).” (Sterman, 1994, p. 293).

Creativity occurs at the interface of three subsystems: An Individual who absorbs information from the culture and changes it in a way that will be selected by the relevant Field of gatekeepers for inclusion into the Domain, from whence the novelty will be accessible to the next generation (see Fig. 3).

The systems model of creativity is formally analogous to the model of evolution based on natural selection. The variation which occurs at the individual level of biological evolution corresponds to the contribution that the person makes to creativity; the selection is the contribution of the field, and the transmission is the contribution of the domain to the creative process (cf. Simonton, 1988; Martindale, 1989). Operating within a specific cultural framework, a person makes a variation on what is known, and if the

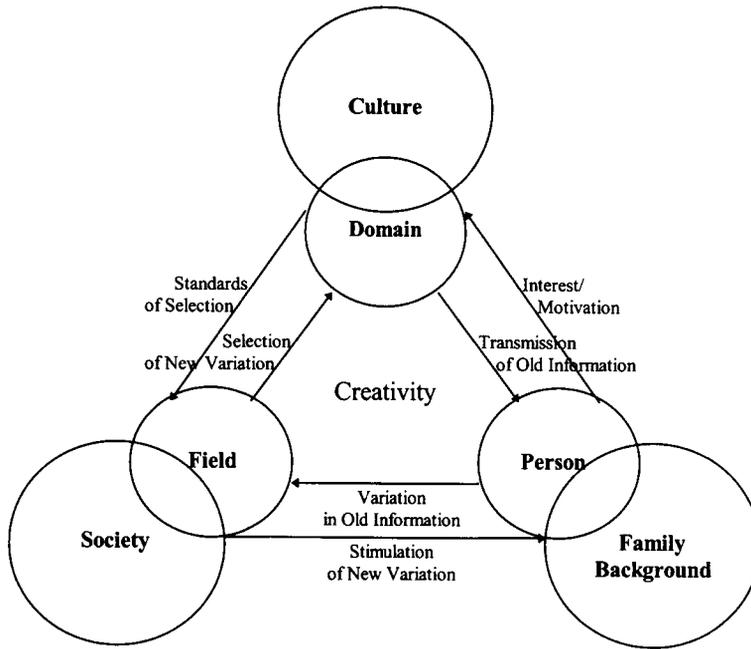

Figure 3. The Systems Model of Creativity.

change is judged to be valuable by the field, it will be incorporated into the domain, thus providing a new cultural framework for the next generation of persons (Csikszentmihalyi, 1988b). Thus creativity can be seen as a special case of evolution. Creativity is to cultural evolution as the mutation, selection, and transmission of genetic variation is to biological evolution. In creativity, it makes no sense to say that a beneficial step was the result of a particular person alone, without taking into account environmental conditions. To be creative, a variation has to be adapted to its social environment, and it has to be capable of being passed on through time.

What we call creativity always involves a change in a symbolic system—a change that, in turn, will affect the thoughts and feelings of other members of the culture. A change that does not affect the way others think, feel, or act will not be creative. Thus creativity presupposes a community of people who share ways of thinking and acting, who learn from each other and imitate each other's actions. Instead of 'genes', it is useful to think about creativity as involving a change in *memes*—the units of imitation that Dawkins (1976) suggested were the building-blocks of culture. Memes are similar to genes in that they carry instructions for action. The notes of a song tell us what to sing; the recipes for a cake tell us what ingredients to mix and how long to bake, the rules of mathematics tell us how to operate with numbers. But whereas genetic instructions are transmitted in the chemical codes we inherit on our chromosomes, the instructions contained in

memes are transmitted through learning. By and large we learn memes and reproduce them without change. The great majority of individuals are perfectly content to obey cultural instructions without dreaming of changing them. But occasionally some people develop the notion that they can write a new song, bake a better recipe, or develop a new equation—and then we may have creativity.

Creativity is the engine that drives cultural evolution. The notion of 'evolution' does not imply that cultural changes necessarily follow some single direction, or that cultures are getting any better as a result of the changes brought about by creativity. Following its use in biology, evolution in this context means increasing complexity over time. In turn, complexity is defined in terms of two complementary processes (Csikszentmihalyi, 1993, 1996). First, it means that cultures tend to become *differentiated* over time—they develop increasingly independent and autonomous domains. Second, the domains within a culture become increasingly *integrated*; that is, related to each other and mutually supportive of each others' goals—in analogy to the differentiated organs of the physical body that help each others' functioning.

#### *The Place of Schools in the Systems Model*

If we apply this model to educational institutions, schools might be seen as consisting of the same three components: a body of knowledge to be transmitted (Domain), teachers who control the knowledge (Field), and finally a number of individuals, the

students, whose task is to learn the knowledge and who are evaluated by teachers in terms of their learning.

This perspective immediately makes clear why schools and creativity are inimical. In a creative process, the point is to innovate on the content of the domain in such a way that the field will deem the innovation better than what existed before. But in schools, the point is for the students to replicate the content of the domain as closely as possible, without deviations. The teachers' task is to ensure conformity with prior knowledge, without even trying to evaluate whether the students' deviations might be 'better' than what is written in the textbooks. Thus the main task of schools is to transmit knowledge with as little change as possible—a necessary task which many might argue should not be tampered with.

On the other hand, good teachers everywhere have always been alert for signs of original thinking in their students. Even though it is very rare for a young student to improve on the content of an existing discipline, the very fact of trying to invent a new poetic expression, or a more efficient mathematical calculation, is taken by some teachers to show an involvement with learning that is extremely important to encourage and nurture. From such a perspective learning can be seen as a rehearsal and preparation for later creativity, when the student has mastered the content of the domain to the point that he or she can make a genuinely valuable innovation in it.

In terms of Education as an institution, typically the individual student, teacher, or administrator submits a novel idea to the teacher, administration, or school board, respectively. This field then selects which *good* ideas are to be, respectively, added to the curriculum, passed on to a higher level of management, or implemented as policy. The cumulative sum of these decisions becomes the domain of Education.

Figure 4 describes the specific manifestation of creativity in the classroom. When a student produces a variation in the curriculum of a subject, a variation that

the teachers feel is worthy of being preserved in some form, then we can observe an instance of creativity. Of course, the problem usually is that teachers are neither looking for innovations from their students, and even if they notice a promising one they have few mechanisms for incorporating it into the curriculum. It is for this reason that most instances of creativity in schools occur outside the classroom, such as in science fairs, artistic competitions, literary prizes, and so on.

### The Individual's Contribution to Creativity

We have said that creativity occurs when a person makes a change in a domain, a change that will be transmitted through time. Some individuals are more likely to make such changes, either because of personal qualities, or because they have the good fortune to be well-positioned with respect to the domain—they have better access to it, or their social circumstances allow them more free time to experiment.

The systems model makes it possible to see the contributions of the person to the creative process in a theoretically coherent way. In the first place, it brings attention to the fact that before a person can introduce a creative variation, he or she must have access to a domain, and must want to learn to perform according to its rules. This implies that motivation is important—a topic already well understood by scholars in the field of creativity. But it also suggests a number of additional factors that are usually ignored; for instance, that cognitive and motivational factors interact with the state of the domain and the field. For instance, the domain of nuclear physics promised many interesting intellectual challenges during the first half of this century, and therefore it attracted many potentially creative young people; now the domain of molecular genetics has the same attraction.

Second, the system model reaffirms the importance of individual factors that contribute to the creative process. Persons who are likely to innovate tend to have personality traits that favor breaking rules, and early experiences that make them want to do so. Divergent thinking, problem finding, and all the other factors that psychologists have studied are relevant in this context.

Finally, the ability to convince the field about the virtue of the novelty one has produced is an important aspect of personal creativity. One must seize the opportunities to get access to the field and develop a network of contacts. The personality traits that make it possible for one to be taken seriously, the ability to express oneself in such a way as to be understood are also part of the individual traits that make it easier for someone to make a creative contribution.

### Personal Qualities

Having the right background conditions is essential, but certainly not sufficient, for a person to make a

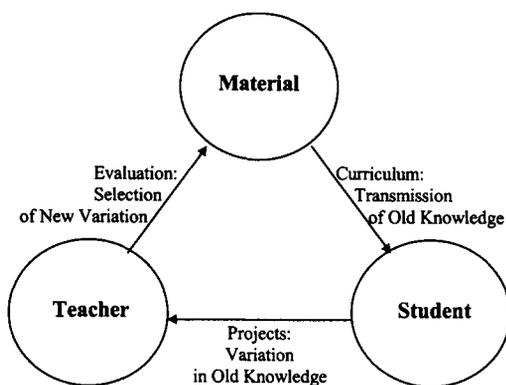

Figure 4. A Model of Creativity in the Classroom.

creative contribution. He or she must also have the ability and inclination to introduce novelty into the domain. These are the traits that psychologists have most often studied, and it is to these that we shall now turn. Because the individual traits of creative people have been so widely studied, we shall only touch on them briefly and without being able to do them justice.

Perhaps the most salient characteristic of creative individuals is a constant curiosity, an ever renewed interest in whatever happens around them. This enthusiasm for experience is often seen as part of the 'childishness' attributed to creative individuals (Gardner, 1993; Csikszentmihalyi, 1996). Without this interest, a person would be unlikely to become immersed deeply enough in a domain to be able to change it.

Besides this indispensable quality of being curious and interested, the picture becomes more complicated. One view we have developed on the basis of our studies is that creative persons are characterized not so much by single traits, but rather by their ability to operate through the entire spectrum of human characteristics. So they are not just introverted, but can be both extroverted and introverted depending on the phase of the process they happen to be involved in at the moment. When gathering ideas a creative scientist is gregarious and sociable; but as soon as he starts working, he might become a secluded hermit for weeks on end. Creative individuals are sensitive and cold, arrogant and humble, masculine and feminine, as the occasion demands (Csikszentmihalyi, 1996). What dictates their behavior is not a rigid inner structure, but the demands of the interaction between them and the domain in which they are working.

In order to want to introduce novelty into a domain, a person should first of all be dissatisfied with the status quo. It has been said that Einstein explained why he spent so much time on developing a new physics by saying that he could not understand the old physics. Greater sensitivity, naiveté, arrogance, impatience, and higher intellectual standards have all been adduced as reasons why some people are unable to accept the conventional wisdom in a domain, and feel the need to break out of it.

Values also play a role in developing a creative career. There are indications that if a person holds financial and social goals in high esteem, it is less likely that he or she will continue for long to brave the insecurities involved in the production of novelty, and will tend to settle instead for a more conventional career (Getzels & Csikszentmihalyi, 1976; Csikszentmihalyi, Getzels & Kahn, 1984). A person who is attracted to the solution of abstract problems (theoretical value) and to order and beauty (aesthetic value) is more likely to persevere.

Another way of describing this trait is that creative people are intrinsically motivated (Amabile, 1983).

They find their reward in the activity itself, without having to wait for external rewards or recognition. A recurring refrain among them goes something like this: "You could say that I worked every day of my life, or with equal justice you could say that I never did any work in my life." Such an attitude greatly helps a person to persevere during the long stretches of the creative process when no external recognition is forthcoming.

The importance of motivation for creativity has long been recognized. Cox advised that if one had to bet on who is more likely to achieve a creative breakthrough, a highly intelligent but not very motivated person, or one less intelligent but more motivated, one should always bet on the second (Cox, 1926). Because introducing novelty in a system is always a risky and usually an unrewarded affair, it takes a great deal of motivation to persevere in the effort. One recent formulation of the creative person's willingness to take risks is the 'economic' model of Sternberg and Lubart (Sternberg & Lubart, 1995).

Probably the most extensively studied attributes of the creative cognitive style are divergent thinking (Guilford, 1967) and discovery orientation (Getzels & Csikszentmihalyi, 1976). Divergent thinking—usually indexed by fluency, flexibility, and originality of mental operations—is routinely measured by psychological tests given to children, which show modest correlations with childish measures of creativity, such as the originality of stories told or pictures drawn (Runco, 1991). Whether these tests also relate to creativity in 'real' adult settings is not clear, although some claims to that effect have been made (Torrance, 1988; Milgram, 1990). Discovery orientation, or the tendency to find and formulate problems where others have not seen any, has also been measured in selected situations, with some encouraging results (Baer, 1993; Runco, 1995). As Einstein and many others have observed, the solution of problems is a much simpler affair than their formulation. Anyone who is technically proficient can solve a problem that is already formulated; but it takes true originality to formulate a problem in the first place (Einstein & Infeld, 1938).

Some scholars dispute the notion that problem finding and problem solving involve different thought processes; for example the Nobel-prize winning economist and psychologist Herbert Simon has claimed that all creative achievements are the result of normal problem-solving (Simon, 1985, 1988). However, the evidence he presents, based on computer simulation of scientific breakthroughs, is not relevant to the claim, since the computers are fed pre-selected data, pre-selected logical algorithms, and a routine for recognizing the correct solution—all of which are absent in real historical discoveries (Csikszentmihalyi, 1988a, c).

The personality of creative persons has also been exhaustively investigated (Barron, 1969, 1988).

Psychoanalytic theory has stressed the ability to regress into the unconscious while still maintaining conscious ego controls as one of the hallmarks of creativity (Kris, 1952). The widespread use of multi-factor personality inventories suggest that creative individuals tend to be strong on certain traits such as introversion and self-reliance, and low on others such as conformity and moral certainty (Csikszentmihalyi & Getzels, 1973; Getzels & Csikszentmihalyi, 1976; Russ, 1993).

How these patterns of cognition, personality, and motivation develop is still not clear. Some may be under heavy genetic control, while others develop under the conscious direction of the self-organizing person. In any case, the presence of such traits is likely to make a person more creative if the conjunction with the other elements of the system—the field and the domain—happen to be propitious.

### Measurement Techniques

How can one appropriately measure individual creativity? By definition, the ability to develop useful products never before developed seems quite *unpredictable*. Nevertheless, some attempts have been made. To expand on the categories of Davis (1983), these approaches are summarized by the following five methods: *Self-Assessment*, *Peer Nomination*, *Personality Correlates*, *Divergent Thinking Tests*, and *Historical Recurrence* (for greater detail see Davis, 1997; Wolfe, 1997).

One method is *Self-Assessment*. This approach elicits the subject's opinion of himself. A substantial problem with such tools is the desirability effect. People like to think of themselves of possessing a positive trait such as creativity. Other people are too modest to accurately report their own strengths. Further, it is extremely difficult to lay out a standard from which the subject can judge what is *creative*. Consequently, popular stereotypes shared in the culture conflate the findings.

A second method is *Peer Nomination*. This approach allows respondents to evaluate each other. The idea is that while creativity is difficult to operationalize, people will recognize it when they see it. As with self-assessment, this measure does not require an external framework. But unlike self-assessment, with other people evaluating the subject, the desirability effect is less intrusive. Amabile (1983) and Csikszentmihalyi (1996) are among those who have used this method by asking experts in specific domains to judge each other. This approach explicitly includes a component of social evaluation.

A third method is *Personality Correlates*. This approach uses personality traits to predict creativity. Dispositions believed to be associated with creativity include confidence, risk-taking, curiosity, and tolerance for ambiguity. Davis and Rimm (1982) developed an

omnibus test called the *Group Inventory for Finding Interests* (GIFFI) I and II based on these assumptions. The problem with this approach is that in real life personality traits are dependent on context. What is important is whether these traits are present in a particular situation, within a particular domain. Furthermore, as previously argued the creative person is distinguished by the ability to alternate between usually fixed characteristics. For instance, he or she must be conformist enough to learn the knowledge available in the domain, and non-conformist enough to want to change it.

A fourth approach measures *Divergent Thinking*. Here creative ability is measured by the quality and quantity of responses to a series of hypothetical problems. The best known creativity tests are the Torrance Tests of Creative Thinking (TTCT) (Torrance, 1966; Davis, 1983, 1997). These pencil and paper tests show reasonable relationships to the preceding general creative personality traits. There is a question, however, as to how the hypothetical problems presented in divergent thinking tests translate into real life. Whether generating numerous fantastic uses for a box really predicts any sort of creative achievement is unclear. Further, divergent thinking as a general skill may not represent the reality of a domain specific world. Some support does exist for the generalizability of divergent thinking tests to creative behavior in later life as reported by Torrance (1988). An advantage of these tests is that they may pick up unrealized potential, if such a thing exists.

A fifth method is *Historical Recurrence*. This approach uses biographical data from previous creative involvement to predict future creative involvement. Simonton wrote "What distinguishes the [creative] genius is merely the cognitive and motivational capacity to spew forth a profusion of chance permutations pertaining to a particular problem" (1988b, p. 422). It follows that participation in a particular domain and public recognition of that participation can be measured and used as a predictive tool. Milgram (1990) designed a useful test for measuring creative activity and achievement applicable to ordinary school children. A criticism of this method is that it does not pick up latent divergent thinking ability. But is the detached latent ability of an individual relevant? The ability to merely think in original ways may not be an appropriate predictor of creative achievement. Csikszentmihalyi (1990a) has tried to measure the mechanism through which intrinsic motivation operates. In studying the creative *experience*, he coined the term 'flow' to describe the feeling people report when skills become so second nature that everything one does seems to come naturally, and when concentration is so intense that one loses track of time. Csikszentmihalyi argued that it is this optimal feeling of flow that fuels the intrinsic motivation engine which propels creativity (Schmidt & Wolfe, 1998).

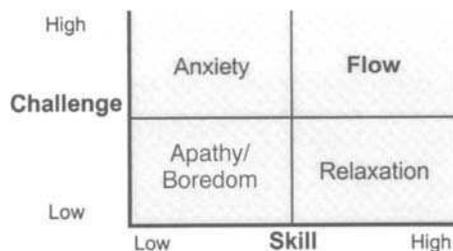

Figure 5. The Experience of Flow.

### Flow

People report the most positive experiences and the greatest intrinsic motivation when they are operating in a situation of high opportunities for action (Challenges) and a high capacity to act (Skills); see Fig. 5.

Flow experiences also play a critical role in the development of complex patterns of thought and behavior and in the successful development of talent. This theoretical assumption has received empirical support in studies of adolescents (Csikszentmihalyi, Rathunde & Whalen, 1993; Adalai-Gail, 1994; Hektner, 1996; Heine, 1996).

### Educational Implications at the Individual Level

In applying the Systems Model to education we shall begin on familiar ground, at the level of the person. After all, the great majority of psychological research assumes that creativity is an individual trait, to be understood by studying individuals. Considering which personal characteristics promote variation in thought and behavior suggests the following implications for educational practice.

#### *Students' Curiosity and Interest are the Main Sources of Potential Creativity* (Csikszentmihalyi, 1996)

To the extent that the curriculum and the methods of instruction will stimulate and sustain students' interests, the likelihood of them being motivated to ask new questions and explore divergent solutions will be enhanced. Unfortunately pedagogy usually either takes students' interests for granted, or ignores them altogether. One of the most important pedagogical steps would be for teachers to acquaint themselves with each student's particular inclination and interest, so that the curricular material could be connected with it.

#### *Potential Creativity is Enhanced by Intrinsic Motivation, and Suppressed by Excessive Reliance on Extrinsic Rewards*

If students learn to enjoy the acquisition of knowledge for its own sake, they will be more likely to engage in extended exploration and experimentation (Amabile, 1983). If teachers use mainly extrinsic rewards—grades, discipline, promises of conventional success—as inducements to study, it is less likely that

students will be stimulated to think new thoughts. Enjoyment does not imply relaxation or laziness; the most enjoyable activities are usually those that require great effort and skill.

#### *Activities Need to be Designed With the Conditions Necessary for Flow in Mind*

To experience flow, a challenging activity must meet the skills of the student. Therefore activities must be adapted, or at least adaptable, for each student's ability. Additionally, activities need to be designed such that goals are clear and relevant feedback is not delayed. Without clear goals, students are not certain where they should be headed; and without immediate feedback, they are not sure whether or not they are successfully headed toward that goal.

#### *Learning to Formulate Problems Should be Part of the Curriculum*

Educational practice currently relies almost exclusively on teaching students how to solve problems. The ability to formulate new problems (Getzels & Csikszentmihalyi, 1976)—or even to engage in divergent thinking—is seldom encouraged and even more rarely taught. Yet these are among the essential cognitive requirements for potentially creative thought.

#### *Respecting Creative Personality Traits*

Students who are potentially creative are almost by definition unusual in their attitudes, values, and demeanor. Therefore, they often come in conflict with teachers who consider their responsibility to enforce conformity and discipline. As a result, many young people who might contribute useful new ideas are intimidated into mediocrity. It is important for teachers to tolerate the idiosyncrasies of children who are otherwise curious and committed to learning.

#### *Promoting the Internalization of Learning*

A young person will be best prepared to introduce valuable novelty into a domain if he or she has identified himself with the rules and contents of a given discipline, and developed internal criteria of excellence in it. It is more important to nurture development of these internal standards than to make sure that students are able to perform according to standards set externally, as when they take tests and examinations.

### The Contribution of the Domain

A new idea can be observed only against the background of already accepted ideas. These are grouped into domains that constitute the heritage of information we call a 'culture'. The purpose of education is to acquaint individuals with the contents of the most important domains. Howard Gardner (1983) has argued that there are at least seven main classes of such domains, each based on specific neurological potentialities. These include linguistic (e.g. poetry, literature,

rhetoric, drama), logical-mathematical, musical, spatial (e.g. painting, sculpture, architecture), bodily-kinesesthetic (e.g. dance, athletics), interpersonal (e.g. politics) and intrapersonal (e.g. philosophy, psychology) domains. Schools typically address only the content of the first two groups, and the emphasis is almost exclusively on the transmission of information, not on innovation.

As the system models suggests (cf. Fig. 3), in order for a creative process to begin, it is necessary that individuals become interested to assimilate the contents of a domain, and for the information contained in the domain to be transmitted to the person. These conditions suggest several issues for the enhancement of creativity in schools.

### **Educational Implications at the Level of the Domain**

Among the issues to be considered for educational practice are the following questions.

#### *How Attractive is the Information Presented to Students?*

Regardless of the domain, if the information in it is not connected to students' interests and needs, few students will be motivated to learn beyond what is required to get good grades, and hence few will be in a position to know where the lacunae in knowledge are located, or will be moved to formulate new problems.

Given the nature of learning, it is inevitable that teachers should provide structure and goals to the curriculum, but unless students have some latitude in exploring and making decisions about the acquisition of their own knowledge, it is unlikely that they will feel enough ownership about the material to want to play with it for its own sake. The flow model also suggests that being able to match challenges with skills—in other words, to access information that is neither too difficult nor too easy—is essential for students to be attracted to learning.

#### *How Accessible is the Information?*

Often the creative process cannot start for the simple reason that the necessary information is either unavailable, or difficult to access. Textbooks and lectures are often unnecessarily abstract and mystifying, so that even motivated students often give up in frustration. It is important to encourage students to explore as many sources of information as possible, and to allow them some flexibility to do so at their own pace. Computers and the internet have a mixed record in supporting the acquisition of personalized knowledge so far, but these new information technologies have a great potential for making the contents of domains accessible.

#### *How Integrated is the Information?*

While it is important to delineate clearly the boundaries and limitations of each subject matter, it is also

important for teachers to show how each subject relates to others—both differentiation and integration are essential for complex learning. Creative problems often arise at the interface of disciplines, and thus excessive compartmentalization stifles genuinely new ideas.

It is also important to help students integrate the knowledge they are acquiring—whether it is mathematics or history—to the issues students already know, and to what they care about. Few students care enough about purely abstract information to want to experiment with it. Courses that combine different disciplines (e.g. 'Physics for Poets') are only the first step in this direction; much more effort could be devoted to the planning of integrated curricula that while preserving the integrity of distinct domains, will attempt to show their mutual interaction.

#### *Are there Opportunities for Mentorships and Apprenticeships?*

In many domains, it is essential for a young person to be trained by experts as soon as possible, or the potential for creativity will not be fulfilled (Bloom, 1985). To study physics or music long enough to be able to innovate in it depends in part on whether there are laboratories or conservatories in which one can practice and learn state-of-the-art knowledge in the particular domain. Parents have to be able to afford tutors as well as the time and expense involved in driving the child back and forth to lessons and competitions. The careers of creative individuals are often determined by chance encounters with a mentor who will open doors for them, and such encounters are more likely in places where the field is more densely represented—certain university departments, laboratories, or centers of artistic activity.

Schools can contribute to matching potentially creative young people with tutors and enhancement programs through tests for identifying talent, and the organization of mentorships.

### **The Contribution of the Field**

Novel ideas are not recognized or adopted unless they are sanctioned by some group entitled to make decisions as to what should or should not be included in the domain. These gatekeepers are what we call here the *field*. The term 'field' is often used to designate an entire discipline or kind of endeavor. In the present context, however, we want to define the term in a more narrow sense, and use it to refer only to the social organization of the domain—to the teachers, critics, journal editors, museum curators, textbook writers and foundation officers who decide what belongs to a domain and what does not. In physics, the opinion of a very small number of leading university professors was enough to certify that Einstein's ideas were creative. Hundreds of millions of people accepted the judgment of this tiny field, and marveled at Einstein's creativity without understanding what it was all about. It has

been said that in the United States ten thousand people in Manhattan constitute the field in modern art. They decide which new paintings or sculptures deserve to be seen, bought, included in collections—and therefore added to the domain. A society can then be defined as the sum of its interrelated fields—from architects to zookeepers, from mothers to consumers of computer peripherals.

The recognition that culture and society are as involved in the constitution of creativity certainly does not answer all the questions. In fact, it brings a host of new questions to light. New ideas often arise in the process of artistic or scientific collaboration (Dunbar, 1993; Csikszentmihalyi & Sawyer, 1995), and peers play an important role in supporting the creativity of individuals (Mockros & Csikszentmihalyi, 2000).

Perhaps the major new question this perspective brings to light is: Who is entitled to decide what is creative? According to the individual-centered approach, this issue is not problematic. Since it assumes that creativity is located in the person and expressed in his or her works, all it takes is for some 'expert' to recognize its existence. So if some kindergarten teachers agree that a child's drawing is creative, or a group of Nobel Prize physicists judge a young scientist's theory creative, then the issue is closed, and all we need to find out is how the individual was able to produce the drawing or the theory.

But if it is true, as the systems model holds, that attribution is an integral part of the creative process, then we must ask: What does it take for a new meme to be accepted into the domain? Who has the right to decide whether a new meme is actually an improvement, or simply a mistake to be discarded? How are judgments of creativity influenced by the attributional process (Kasof, 1995)?

In any case, the point is that how much creativity there is at any given time is not determined just by how many original individuals are trying to change domains, but also by how receptive the fields are to innovation. It follows that if one wishes to increase the frequency of creativity, it may be more advantageous to work at the level of fields than at the level of individuals. For example, some large organizations such as Motorola, where new technological inventions are essential, spend a large quantity of resources in trying to make engineers think more creatively. This is a good strategy as far as it goes, but it will not result in any increase in creativity unless the field—in this case, management—is able to recognize which of the new ideas are good, and has ways for implementing them—i.e. including them in the domain. Whereas engineers and managers are the field who judge the creativity of new ideas within an organization such as Motorola, the entire market for electronics becomes the field that evaluates the organization's products once these have been implemented within the organization. Thus at one level of analysis the system comprises the organization

with innovators, managers, and production engineers as its parts; but at a higher level of analysis the organization becomes just one element of a broader system that includes the entire industry.

Teachers constitute a field that judges the ideas and products of students. It is they who decide which test responses, essays, or portfolios are to be considered creative. So it is true that teachers can measure creativity—as long as it is recognized that what is meant by 'creativity' is not a real objective quality, but refers only to the acceptance by teachers. Such creativity, while part of the domain of Education, may have nothing to do with creativity in any other domain outside of it. At every level, from considering Nobel Prize nominations to considering the scribbles of four-year olds, fields are busy assessing new products and deciding whether or not they are creative—in other words, whether they are enough of an improvement to deserve inclusion in a particular domain. And as the biographies of creative individuals suggest, teachers are not particularly good at recognizing future creativity in their students.

## Educational Implications at the Level of the Field

### *The Role of Funding*

Other things being equal, a school that enjoys material resources is in a better position to help the creative process. A wealthier school is able to make information more readily available, allows for a greater rate of specialization and experimentation, and is better equipped to reward and implement new ideas. Sub-sistence schools have fewer opportunities to encourage and reward novelty, especially if it is expensive to produce. Only schools with ample material reserves can afford to build great gymnasiums, great auditoriums, great scientific laboratories

### *How Open are Teachers to New Ideas?*

It is important that teachers enjoy students' explorations beyond the boundaries of textbooks and lesson plans, instead of feeling threatened by them. Teachers who allow deviation from the curriculum, who encourage students to ask questions, to explore alternative paths to solve problems, are more likely to see novelty produced by their students.

### *Do Teachers Stimulate Students' Curiosity and Interest?*

Given the importance of problem formulation in the creative process, it seems important for teachers to stimulate students to find and frame problems of their own, problems that they care about. Every field sooner or later develops self-serving tendencies, so that the effort of its members goes towards making life easier for themselves instead of serving the social purposes for which they are paid.

For teachers, the danger is to teach with the least effort, relying on familiar formulae and texts, without regard for the needs and interests of students. Teachers can stimulate creativity by keeping their lessons and outlines fresh, by exposing students to extracurricular opportunities to learn, by getting to know the interests and strengths of their students.

#### *Can Teachers Distinguish Good New Ideas from Bad Ones?*

As the evolutionary model makes clear, most variations are not an improvement on existing knowledge. Teachers who praise every novelty without discrimination do not help students develop the essential internalized criteria that will eventually allow them to make informed evaluations of their own ideas.

Like good parenting, good teaching requires both support and challenge, appreciation and evaluation, freedom and discipline (Csikszentmihalyi, Rathunde & Whalen, 1993). Here again extracurricular opportunities could help classroom activities: science fairs, writing contests, athletic tournaments expose students to accepted criteria of evaluation, helping them to internalize standards.

#### *Are There Ways of Implementing Student Creativity in the School?*

Recognizing a valuable novelty is the first step of the process, but bringing it to fruition is equally important. Schools can help through the production of plays, compositions, math competitions, science fairs. Similarly, it is important to pass the novel product on to others. Publication in a school paper or literary magazine, or a publicly viewed art exhibit, play, or science fair allow novelty to spread beyond the classroom.

#### **Conclusion**

It is perhaps unrealistic to expect schools to become a major force in the development of creativity. After all, the major function of formal education is to pass on knowledge to young people as accurately as possible, without losing much of the hard-earned knowledge of previous generations in the process. Yet, as we have argued, the future will require individuals who are able to formulate new problems, come up with new solutions, and adapt readily to the new ideas of others. Much of this training for a flexible, creative approach to information should be the responsibility of schools.

Traditionally, education has been focused on transmitting the knowledge of major socially sanctioned domains (i.e. Science, Mathematics, Literature), at the expense of encouraging the evolution of those domains which might lead to individual variation through challenging questions and original answers. The Systems Model suggests an important issue: To foster creativity, education needs to do more than transfer

information from teacher to student. So, without sacrificing the domain's information *transmission*, how can educators add to the field's value *selection* and the student's product *variation*?

Creativity in the past has been viewed as a mental process, as the product of individual genius. But new ideas come from existing domains of knowledge; problems arise and standards are internalized from them. And we know whether or not an original solution is worth implementing because of the evaluation of an expert field. It is certain that psychologists interested in the phenomenon of creativity will continue to focus on the individual and his or her thought processes. After all, the unique qualities of creative geniuses are so attractive that we cannot curb our curiosity about them.

What the present chapter seeks to accomplish, however, is to point out that creativity cannot be recognized except as it operates within a system of cultural rules, and it cannot bring forth anything new unless it can enlist the support of experts. If these conclusions are valid, then it follows that the occurrence of creativity in schools is not simply a function of how many gifted students there are, but also of how accessible is the information they need, and how responsive teachers are to novel ideas. Instead of focusing exclusively on students, it makes more sense to focus on educational institutions that may or may not nurture novelty. For in the last analysis creativity in schools is a joint result of well-presented knowledge, interested students, and stimulating teachers.

# Giftedness in Non-Academic Domains: The Case of the Visual Arts and Music

Ellen Winner<sup>1</sup> and Gail Martino<sup>2</sup>

## Introduction

It is common to distinguish between giftedness and talent. Children who are advanced in scholastic abilities or have a high IQ are labeled gifted, while those who show exceptional ability in an art form or an athletic area are called talented. In this chapter we argue against such a distinction, and refer to children with talent in an art form as gifted.

While there is no necessary link between a gift in art or music and a gift in terms of high IQ (Shuter-Dyson, 1986; Csikszentmihalyi, Rathunde & Whalen, 1993; Winner, 1996a; Miller, 1999), children with high ability in an art form are similar to academically gifted children in three respects (Winner, 1996a). First, they are precocious; they master the first steps in their domain at an earlier than average age and learn more rapidly in that domain. Second, they have a 'rage to master'—that is, they are intensely motivated to make sense of their domain and show an obsessive interest and ability to focus sharply in their area of high ability. In the visual arts, this means that they produce a large volume of work over a sustained period of time (Golomb, 1992; Pariser, 1997; Milbrath, 1998). In music, where giftedness usually emerges in performance rather than composition, this means that children develop a large repertoire of music that they can perform (Winner, 1996a). And third, they 'march to their own drummer', meaning that they do not just learn faster than ordinary children, they also learn differently. They learn virtually on their own, requiring minimum adult scaffolding, and often solve problems in their domain in novel, idiosyncratic ways.

Because these children solve problems in unusual ways, they are creative. But we distinguish sharply here between two levels of creativity: little-c and big-C creativity (Winner, 1997). Gifted children are creative

in the little-c sense, meaning that they solve problems in novel ways and make discoveries about their domain on their own. Big-C creativity, or domain creativity, involves changing the domain. There is considerable evidence that creators do not make domain-altering changes until they have worked for at least ten years in their area (Gardner, 1993; Simonton, 1994). (Mozart and Picasso both created works as young children, but their domain-altering contributions came from their adult works.) Thus, children by definition cannot be domain creative.

In this chapter we consider three questions about giftedness in the visual arts and music. First, what are the characteristics typically displayed by children with such gifts? Second, what is the role of environmental factors in the development of these gifts? Third, what is the relationship between early prodigiousness in art and music and domain creativity in these areas in adulthood?

## Characteristics of Children Gifted in Visual Arts

Children who may be labeled 'gifted' in drawing are not just more advanced than typical children in drawing milestones. Rather, they draw in a qualitatively different way. This has been demonstrated by Milbrath (1998) in a longitudinal and cross-sectional study of gifted young artists. Prior to the work of Milbrath, studies of artistically gifted children relied primarily on case studies. Milbrath made an important contribution to the study of artistic giftedness by following eight artistically gifted children over ten years, and also by comparing a group of artistically gifted children between ages 4–14 to a normal control group. Using the terminology of Piaget (Piaget & Inhelder, 1969), she argues that artistically gifted children are guided by 'figurative' rather than 'operational' processes (but see Pariser, 1995, for a critique of using a Piagetian framework to describe artistic milestones). According to Milbrath, these children actually *see* the world differently. To begin with, they encode visual information more accurately, and see the world less in terms of concepts and more in terms of

<sup>1</sup> Boston College and Harvard Project Zero, USA.

shapes and visual surface features. Second, they have superior visual memories (cf. Rosenblatt & Winner [1988] for corroborating evidence). And third, they attend more to the act of drawing itself, they can *see* when something looks wrong, and this leads to discoveries about how to represent the world on paper. Thus, in Milbrath's terms, these children are better at seeing, remembering, and doing.

#### *Ability to Draw Realistically*

Because artistically gifted children use figurative processes to represent (that is, they seem to be able to draw things as they appear, with all the distortions

caused by point of view and perspective), their drawings typically appear highly realistic (Milbrath, 1998). This realism is a hallmark of gifted child art. The 'core' indicator of giftedness in drawing is the ability to draw recognizable shapes at least one year in advance of the normal time of emergence of this skill. While typical children begin to draw recognizable shapes representing objects in the world at around the age of 3 or 4 (Kellogg, 1969; Matthews, 1984; Golomb, 1992), gifted children have been noted to begin to draw representationally at the age of 2. Figure 1 shows a striking contrast between the way in which a typical and an artistically gifted 2-year-old drew

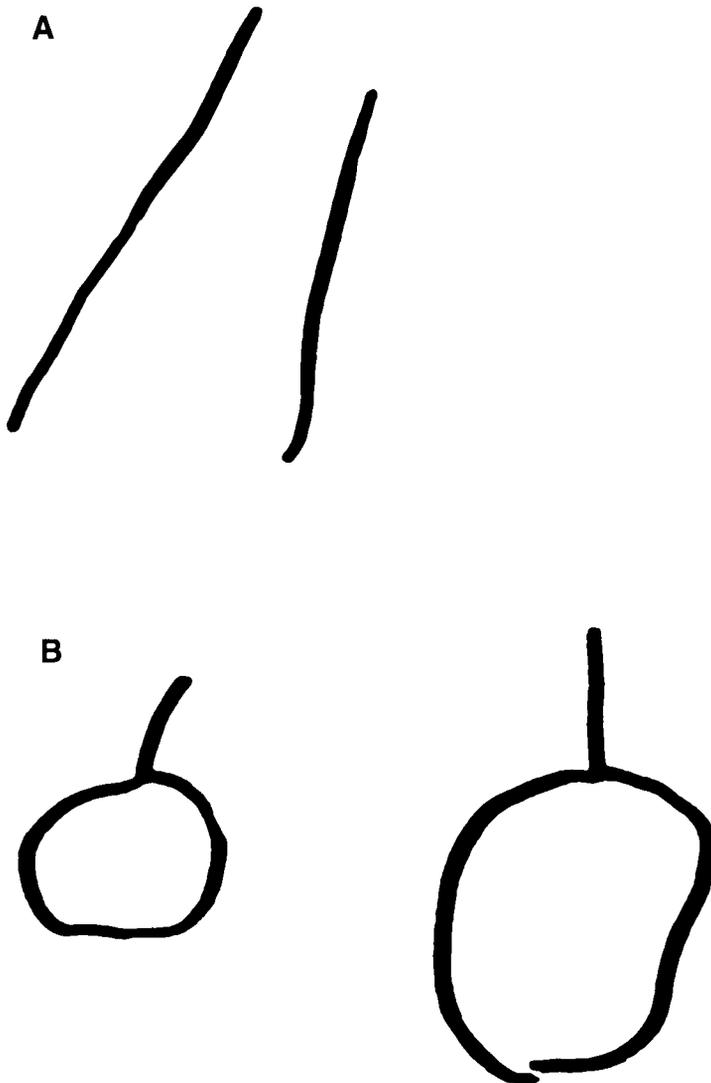

Figure 1. (a) Two apples drawn by 2-year-old on request; (b) Two apples drawn by artistically gifted 2-year-old on request. Reprinted with permission of Ryan Sullivan.

apples. The typical 2-year-old made a slash for each apple because he had not yet acquired the understanding that lines on the page stand for the edges of objects. For him, a line simply stood for 'thingness'. The gifted 2-year-old had grasped the concept of a line standing for an edge, and produced a fluid line describing the contour of each apple.

Milbrath (1998) also notes that a clear sign of artistic giftedness is the ability to use line to stand for edge, in contrast to typical children who use line to stand for thing. In Willats' (1981) terms, ordinary children use a denotation rule by which a one-dimensional picture primitive (i.e. a line) stands for a two-dimensional region or volume. Artistically gifted children bypass this rule. They also bypass another similar denotation rule by Willats (1981). While children ordinarily fill in planes to convey solidity (thereby using a 2-d primitive to stand for a 3-d volume), artistically gifted children emphasize the surface features of a plane by decorating its surface and retaining a line around its edge. In this way a plane is depicted correctly as a two-dimensional form.

Soon after gifted children begin to draw recognizable forms, they also begin to draw in a realistic manner. They are able to capture the precise shapes of objects, they add true-to-life details that most children would never add (e.g. gas tanks on cars), and they begin to represent the illusion of volume and depth. In place of the simple, schematic, flat, charming, child-like forms typically found in child art, one finds remarkable adult-like, differentiated, complex images that suggest an effort to understand and master how objects are structured. Gifted children draw realistic

images quickly and with ease. They do not labor and erase. Instead, their lines are sure and confident (Gordon, 1987; Paine, 1987; Pariser, 1991, 92/93; Milbrath, 1998). The young Picasso, for example, could draw anything upon demand, and liked to start a figure from non-canonical places, for instance, by drawing a dog beginning with the ear (Richardson, 1991) A highly realistic pair of faces, copied by Millais at age 8 from an adult work is shown in Fig. 2.

The ability to draw realistically also means that gifted children's drawings capture the correct proportions of figures. Milbrath (1998) found that gifted children succeed in drawing human figures in proportion between the ages of four and ten. The non-gifted children that she studied were still unable to capture proportion by age 14 (which was the oldest age at which she observed their drawings).

Numerous examples of children with precocious ability to draw realistically have been reported (Kerchensteiner, 1905; Wilson & Wilson, 1976; Gardner, 1980; Hurwitz, 1983; Golomb, 1992; Winner, 1996a; Milbrath, 1998). One of the most striking examples of early realism is found in the work of Eytan, an Israeli child described by Golomb (1992). Eytan's family did not remember whether he scribbled, but the family does have drawings that he produced at 2, an age when most children are just beginning to scribble. At 2, Eytan drew recognizable shapes: people, tractors, fish, cars, etc. Normal children make their first tadpole-like representation of a human at about age 3, and do not differentiate the head from the trunk until several years later. In contrast, Eytan began to draw humans with a differentiated head and trunk at between 2 and 3.

Figure 2. Pencil copy of an adult work drawn by John Everett Millais at age 8.

One way Eytan achieved realism was through the meticulous depiction of details, such as exhaust pipes on his vehicles. Another way that realism was achieved was through the depiction of volume and depth. Typically children in Western culture do not begin to try to depict the third dimension until the middle elementary school years. By the age of  $2\frac{1}{3}$ , Eytan was not content with drawing vehicles from their canonical side view, and invented ways to depict their volume, showing their sides receding into depth. He first used an orthographic projection system to show more than the front or side of a vehicle. By the age of 3 he had abandoned this system and instead showed multiple sides of a vehicle by attaching the top and side faces to the front of a vehicle. After his third birthday, he used a mixture of three projection systems: horizontal and vertical oblique projection; isometric projection (in which the front view of a vehicle was its true rectangular shape, but the top and sides of his trucks were parallelograms); and divergent perspective, in which lines diverge outwards to show the front, top, and both sides of a vehicle. By the time he was 4 he showed an understanding of the perspectival rule that objects receding in the distance are reduced in size, and he was beginning to experiment with foreshortening. Figure 3 shows an attempt at perspective by Eytan at

age  $3\frac{1}{4}$ .

According to Milbrath (1998), because artistically gifted children see the world in terms of its visible surface features, they are able to overcome the object-centered perspective that dominates typical children. Milbrath notes that artistically gifted children begin to make view-specific drawings long before ordinary children do so. This means that their drawings show figures in non-canonical positions (e.g. three-quarter views of faces by age 7, back views, profiles) as well as figures distorted and foreshortened by perspective. She observes, however, that while artistically gifted children use perspectival techniques at an early age, their drawings show mixed viewpoints (e.g. oblique projection mixed with linear perspective). These children do not appear to be able to make drawings with one single coordinated point of view until adolescence. According to Milbrath, the ability to coordinate a drawing through a single viewpoint must await Piagetian formal operations. However, whatever it is that constrains the development of the ability to coordinate a drawing through a unified viewpoint is not yet known, and research is needed to determine whether children could learn to draw with a single viewpoint at a pre-formal age with appropriate training. Given the fact that artistic savants such as Steven Wiltshire are able to use

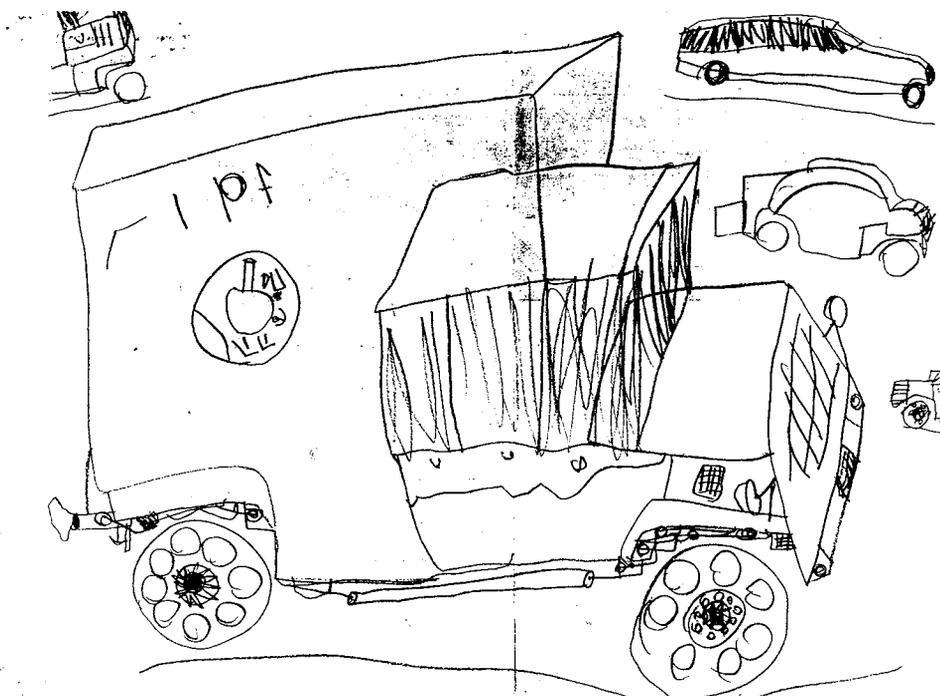

Figure 3. Drawing of a truck by Eytan at age  $3\frac{1}{4}$ . From Claire Golomb, *The child's creation of a pictorial world*. Reprinted with permission of The Regents of the University of California, Copyright & Copy: 1992.

unified perspective despite being autistic and retarded, there are likely to be alternative routes to perspective besides operational understanding, a point on which Milbrath agrees.

The ability to draw realistically at an earlier than average age also marks the childhoods of those who go on to become established artists. Gordon (1987) studied the childhood works of thirty-one Israeli artists and found that all stood out for their early ability to draw realistically. The desire and ability to draw realistically at an early age also characterized the childhoods of those who go on to become sculptors: Sloane and Sosniak (1985) interviewed twenty sculptors about their childhoods, most of whom recalled drawing realistically at an early age. Numerous other well known artists' early drawings have been singled out for their advanced realism: e.g. Millais (Paine, 1987), Landseer (Goldsmith & Feldman, 1989), Sargent (Cox, 1992), and Picasso (Pariser, 1991).

Picasso provides a clear example of the ability to draw highly realistically at an early age. He claimed, perhaps apocryphally, that he bypassed the typical stage of early drawings in which children draw in a fanciful, playful, non-realistic manner. "I have never done children's drawings. Never" (Richardson, 1991, p. 29). However, since we have no records of his works before the age of 9, it is not clear whether this is true. What is clear is that Picasso wanted to see himself as a prodigy. When he went to see a show of child art, he noted, 'As a child I would never have been able to participate in a show of this kind: at age 12, I drew like Raphael' (Richardson, 1991, p. 29). And he recalled specific examples of this adult-like style: "Even when I was very small. I remember one of my first drawings.

I was perhaps six . . . In my father's house there was a statue of Hercules with his club in the corridor, and I drew Hercules. But it wasn't a child's drawing. It was a real drawing, representing Hercules with his club" (Richardson, 1991, p. 29). At 11, Picasso enrolled in his father's academic drawing class, in which students had to make detailed renderings of plaster casts. While most students considered this drudgery, Picasso loved it, and produced technically skilled and precise drawings.

#### *Ability to Master Cultural Conventions*

Realism as an early indicator of artistic giftedness may well be culturally determined. In the West, at least from the Renaissance until the twentieth century, artists have striven to capture the illusion of space, volume, and depth (Gombrich, 1960). While gifted children probably begin to draw realistically long before they have much if any exposure to examples of Western realistic art, they have certainly been exposed to realistic images on billboards, magazines, and picture books. The most well-known non-Western artistic prodigy is Wang Yani, a Chinese child who painted in the Chinese brush and ink style at an adult-like level in the preschool years (Zhensun & Low, 1991). As can be seen in Fig. 4, Wang Yani does not draw or paint in a realistic style, but rather in the style of classical Chinese painting. As young as four, Wang Yani had developed a sense of the adult art world, and could make the kind of art valued by the art 'field' in her culture—i.e. the art historians, the museum curators, etc. Wang Yani uses the classical Chinese wash technique and she paints in the loose spontaneous and abbreviated style of Chinese ink paintings. Thus, as

Figure 4. 'Pull Harder', painting by Wang Yani at age five. Reprinted by permission of Wang Shiqiang.

Goldsmith and Feldman (1989) point out, the technical sophistication of her work reveals itself along dimensions different from those of Western children.

Alexandra Nechita, a Romanian born artistic prodigy now in the United States, provides a similar example (Winner, 1997). She works in oil, on large canvases, some up to 5 feet by 9 feet, and she paints quickly and compulsively, often completing several large paintings in one week. Her paintings are clearly imbued in the Western modernist tradition—Cubism, Fauvism, Expressionism. One can see in them the styles not only of Picasso, but also of Gorky, Kandinsky, and Miro (Fig. 5).

The differences between Wang Yani and Alexandra Nechita are instructive. The domain—the body of works that make up the history of painting in one's culture—is shown here to exert as powerful an influence on child prodigies as on adult artists. It is unlikely that either could have painted as they did without the influence of their respective traditions.

The similarities between the two child artists are just as instructive as their differences. Both have an uncanny sense of the adult art world of their culture, and can paint the kinds of paintings that are prized by this art world. Both have an astonishing mimetic ability that allows them to do this. These two cases tell us not only about the power of the domain, but also about the strong role of the *field*—the gatekeepers, judges, curators and art critics who determine whether a work is considered creative (Csikszentmihalyi, 1988). If Alexandra Nechita had somehow been able to develop her style in China, her works would almost certainly have been seen as odd, as distorted, as ugly, as unskillful, and as something to be discouraged. They would have looked nothing like the art that the adult field values. Because she painted in the West and in the 20th century, where modernism and Picasso are revered, her art looks adult-like and has thus been deemed prodigious. Had she produced her paintings two hundred years ago in the West, her works would surely have attracted a negative reaction. A recent study by Pariser and Vandenberg (1997) found that views of what is considered aesthetic in child art in general (i.e. not specifically gifted child art) is also culturally determined, with Westerners valuing modernism, and Chinese-Americans valuing skill.

Further evidence that we place too high a value on early realism as a sign of artistic giftedness comes from Karpati (1994, 1997), who found that giftedness in design and construction did not predict a high level of ability to draw realistically. She concluded that different aspects of artistic talent are unrelated, and the ability to draw realistically is only one sign of such talent. There is in fact abundant evidence that artistically gifted children do not always draw realistically. Gifted children often draw in cartoon style, and cartoons are a non-realistic cultural convention (Wilson & Wilson, 1976). The childhood drawings of Toulouse

Lautrec were not realistic but were in the style of grotesque and expressive caricatures (Pariser, 1998). As a child, Picasso also often drew caricatures, as well as other playful non-realistic images (Pariser, 1998). Neither Picasso, Lautrec, nor Klee were advanced in the area of spatial rendering (Pariser, 1998). An analysis of Klee's 6-year-old drawings showed them to be at an adult level in realism (using the Goodenough Harris scale) but only at the 6-year-old level in terms of organization of pictorial space (Porath, 1992).

What unites all children with artistic gifts is thus not the ability or proclivity to draw realistically (though this is a common manifestation in the West), but rather the ability to master one or more of the culture's norms of artistry at a very early age. At the heart of artistic talent is the ability to master cultural conventions, whether the convention is realism in the case of Eytan or Millais, modernism's distortion in the case of Alexandra Nechita, grotesque caricature in the case of Lautrec, or allusionistic brush painting in the case of Wang Yani. It is a mistake to be blinded by our Western eyes and see realism as the prime sign of artistic talent, when realism is but one of many possible cultural conventions that artistically gifted children master so early and so independently.

#### *Exploration of a Single Theme*

Picasso viewed paintings as a logical sequence of explorations. "Paintings", he said, "are but research and experiment. I never do a painting as a work of art. All of them are researches. I search constantly and there is a logical sequence in all this research" (Lieberman, 1960, p.33). Many artistically gifted children seem to exemplify this approach. In their drawings, a single theme is explored over and over again. This repeated practice in drawing one kind of subject means that they are far more skilled in drawing their favored subject than in drawing other subjects. For Eytan, for instance, the theme was vehicles, and these were drawn far in advance of his human figures. Wang Yani painted only monkeys until the age of 7 (Goldsmith & Feldman, 1989; Goldsmith, 1992), and was far better at rendering monkeys than horses or humans, just as Lautrec rendered horses better than birds or humans (Pariser, 1997). Kerchensteiner (1905) described G. J. who drew only horses. Gardner (1980) described Gabriel who focused on portraits, and Stuart who focused on comic book style figures. Winner (1996a) described Peter who focused on women in flowing robes. As Pariser (1997, p.41) notes, the work of artistically gifted children is 'thematically specialized'.

#### *The Invention of Imaginary Worlds and the Construction of Narratives*

Particularly in middle childhood and adolescence, artistically gifted children create imaginary settings and fantasy characters in their drawings, and their

drawings depict episodes in the lives of these invented characters. This is the age when gifted children begin to create superheroes and science fiction characters modeled after the images they see in comic books. Wilson and Wilson (1976) note that visual narrative need not be in the form of a series of frames, as in a

comic strip. Each drawing functions as a shorthand for a complex plot. One episode may begin in one sketch book and then continue on disconnected pages. These fantasy worlds allow children an escape into a private world. According to one gifted child, "most people . . . just look at them and say 'that's a pretty picture'

*Figure 5. 'Forgotten Values', Painting by 10-year-old Alexandra Nechita in a style reminiscent of Picasso. Reprinted by permission of International Art Publishers, Costa Mesa, CA.*

without understanding what the people are really like and the story behind them” (Wilson & Wilson, 1976, p. 46). Gifted children are often much more interested in inventing imaginary worlds in their drawings than in experimenting with form and design. In the process, they produce countless drawings, and thus gain fluency and technical skill (Wilson & Wilson, 1976).

#### *Advanced Compositional Strategies*

The compositional strategies of artistically gifted children are advanced in comparison to those of typical children. Golomb (1992) studied the principles of composition in almost 1,500 drawings by typical children from 3–13 years of age. Younger children tended to align the parts of the drawing along either the horizontal or vertical axes. Older children moved on to symmetrical compositions, but only the most talented ones used asymmetrical balance. In contrast, Milbrath (1998) found that the drawings by even her youngest gifted children were constructed according to symmetry as well as complex symmetry and asymmetrical balance. Both complex symmetry and asymmetrical balance use different dimensions as counterbalances. Thus, large size may be counterbalanced by a heavy color. In Fig. 6, the large cat is balanced by the smaller ball of yarn which achieves weight because it is colored an intense yellow. Milbrath hypothesizes that the advanced compositional strategies of artistically gifted children are made possible by the fact that these

children attend closely to the act of drawing itself, and thus can judge the visual weights of shapes, colors, empty spaces, and directional lines.

#### **Characteristics of Children Gifted in Music**

The core ability of the visually gifted child was described as the ability to capture one or more of the culture’s graphic conventions, whether these be realistic depiction, modernism, caricature, or the allusionistic style of Chinese brush painting. The core ability of the musically gifted child is a sensitivity to the structure of music—tonality, key, harmony, and rhythm, and the ability to hear the expressive properties of music. Sensitivity to structure allows the child to remember music, to play it back with ease either vocally or with an instrument, and to transpose, improvise, and even invent. Just as there has been undue focus on realism as the core indicator of artistic giftedness, there has been undue focus on technical and analytic skill as the core indicator of musical giftedness. Sensitivity to expressive properties has been relatively ignored.

Musical giftedness reveals itself as young as 1 or 2, which is perhaps earlier than giftedness in any domain of skill (Scott & Moffett, 1977; Shuter-Dyson & Gabriel, 1981; Shuter-Dyson, 1986). For example, in a survey of forty-seven musicians, Scheinfeld (1956, cited in Shuter-Dyson & Gabriel, 1981) found that their ability had been detected on average at 4 $\frac{1}{2}$ . Drake

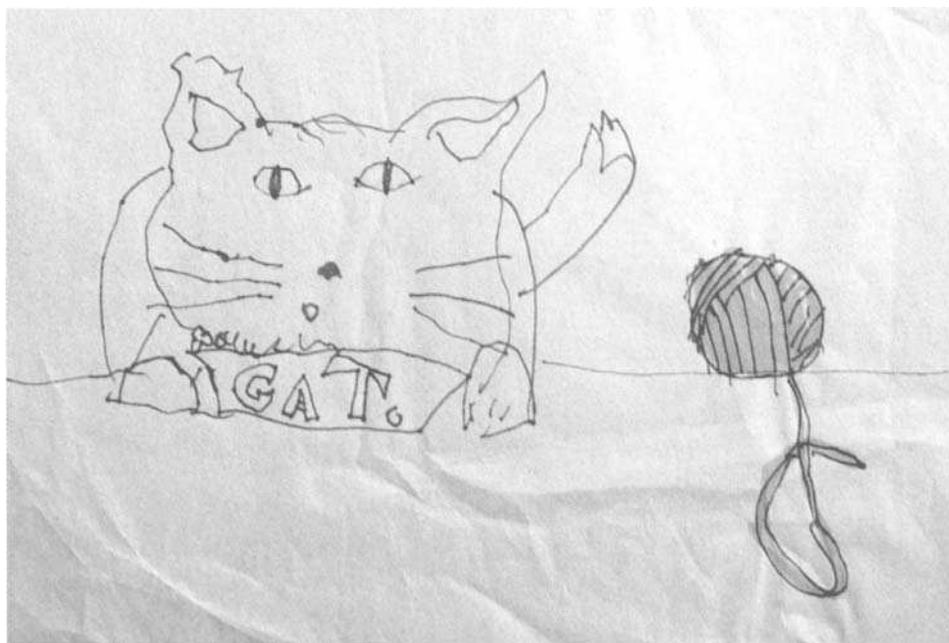

Figure 6. Drawing by an 8-year-old gifted child showing asymmetrical balance. The large cat is balanced by the small ball of yarn because the cat is uncolored and the yarn is bright yellow. The color gives the smaller shape more weight. Reprinted by permission of Constance Milbrath and Cambridge University Press.

(1957, cited in Shuter-Dyson & Gabriel, 1981 found that 70% of the great violinists in Leahy's *Famous Violinists* were prodigies as young children. Mozart composed a concerto for the harpsichord at 4 (Waterhouse, 1988). Mendelssohn was even more of a prodigy, and the violinist Yehudi Menuhin performed with symphony orchestras at 7.

The strikingly early age at which musical giftedness often manifests itself may be a function of music's appeal and accessibility. However, musical talent may not always be recognized at an early age, as shown by Sloboda's (1985) finding that concert pianists are not always recognized as musically gifted in early childhood.

#### *Interest in Musical Sounds*

Perhaps the earliest clue that a child is gifted in music is a strong interest and delight in musical sounds (Scott & Moffett, 1977; Sosniak, 1985; Radford, 1990). Stravinsky's first memories were of song (Gardner, 1992). And Mozart's ear was said to be so delicate that loud sounds made him physically ill (Schonberg, 1970). However, Sloboda (1985) points out that heightened attention to sounds per se is not in itself evidence of musical sensitivity: a response to a sound may simply be due to the infant's natural heightened attentiveness to novelty.

Musical children respond more to music than do average children, showing an intense interest in auditory information, both musical and environmental (Haroutounian, 1998, in preparation; Miller, 1989). Such children often have a strong sense of goodness of tone and timbre. For example, both Rubinstein and Menuhin broke toy violins because the tone of these toys was so poor (Radford, 1990).

#### *Musical Memory*

One of the earliest signs of musical giftedness is the ability to sing back heard songs with accuracy. This ability is made possible by exceptional musical memory, a skill that has been said to be the ability most central to musical talent (Judd, 1988). While children ordinarily begin to sing and talk at about the same age (18 months) (Sloboda, 1985), musically gifted children may begin to sing at a younger age, and often before they can speak (Shuter-Dyson, 1986). E. N., the 7-year-old Hungarian musical prodigy studied by Revesz (1925) did not speak until the age of 3, but before the age of 1 he tried to sing back songs. Revesz reports also that Handel sang before he could speak.

In the normal course of development, children do not try to imitate heard songs until about 2–2½. Children are able to sing portions of these songs with accuracy at around 3, and can sing whole songs by about 4. However, intervals in these songs are only approximate, and children are not yet able to maintain the same tonality through a single song. It is not until about five that children can reproduce with accuracy the

familiar tunes of their culture (Gardner, Davidson & McKernon, 1981; Sloboda, 1985). Musically gifted children present a striking contrast: these children sing with great accuracy, demonstrating the ability to match pitches with precision by their second year (Revesz, 1925).

Musically gifted children can imitate a song after only one exposure, and familiar themes from TV are rapidly and effortlessly learned (Miller, 1989). Mozart began to pick out tunes on the piano at 3 (Schonberg, 1970). Pepito Areola, a child studied by Richet (1900) could play twenty pieces from memory by the age of 3½. At 3, the pianist Arthur Rubinstein listened to his older sister playing the piano and surprised his family by faultlessly playing the pieces she had been practising (Winn, 1979). At the beginning of his fourth year, a Hungarian prodigy, E. N. could reproduce with accuracy on the piano any tune that he overheard (Revesz, 1925); by seven he could play complex Beethoven sonatas from memory. Mozart at 14 was able to write down Alleferi's *Miserere*, a complex piece of music with nine parts, after listening to it only a few times (Henson, 1977).

A series of memory tests administered by Revesz showed the seven-year-old E. N. had a short-term musical memory almost equal to that of an adult musician tested. That is, E. N. performed as well as the musician when asked to listen to pieces of music, commit them to memory, and play them back. Moreover, E. N. revealed a long-term memory far superior to that of the adult musician: both were asked to reproduce music heard 24 hours earlier, but only E. N. succeeded, and he did so effortlessly and flawlessly.

E. N.'s memory gave evidence of a tacit understanding of musical structure: he was better able to recall familiar structure, harmony, and rhythm than random harmonies, and had better recall for the music in the diatonic scale than for dissonant music built on the twelve tone chromatic scale. Thus, his memory was structure-preserving: it was somewhat dependent on familiar structure, and was thus not eidetic, mindless, or literal. Superior recall for familiar form indicates some representation (whether conscious or unconscious) of musical structure. Bamberger (1986) notes that the extraordinary ability of musically gifted children to play back what they hear is non-reflective and tacit. Such children often say that they cannot imitate a piece if they think about it.

#### *Perfect Pitch*

While one might predict that musically gifted children would show perfect pitch—the ability to name notes heard, and the ability to sing notes named—this is not the case. Certainly some prodigies have shown perfect pitch. E. N., for example, at the age of 3 could instantly locate on the piano notes that were sung to him. He could also recognize intervals and the notes in a chord

and analyze chords. In fact, his capacity for resolving multiple chords has hardly ever been equaled (Revesz, 1925). Mozart also had perfect pitch: he could tell when violins were a quarter out of tune by the age of 4 (Schonberg, 1970).

However, perfect pitch is not consistently associated with musical giftedness (Walters, Krechevsky & Gardner, 1985). Rather, perfect pitch is related to the age at which musical instruction was begun, and is far more likely to be found in individuals who began musical instruction before the age of 4 than in those who began as late as 12 (Sergent and Roche, 1973). However, it is certainly possible that children who begin at an early age are those who are more gifted and also those who have perfect pitch.

### *Sight-Reading*

As with the skill of perfect pitch, the ability to sight-read is also not consistently associated with giftedness in music (Walters, Krechevsky & Gardner, 1985). This ability is possessed by some but not all musical prodigies. Mozart possessed this skill. At seven, he could readily play a piece he had never seen before (Scott & Mofett, 1977). E. N. also had this ability at seven.

### *Musical Generativity: Ability to Transpose, Improvise, and Compose*

There is a clear distinction between the act of performing existing music and the creation of new music. A further distinction exists between composing new music and two more constrained forms of creation: transposing a given piece to a new key, and improvising from a given musical theme. The transposer takes a given piece and shifts it to a new key. The improviser takes a given musical theme and improvises from this theme, without changing the essential style and structure of the already existing piece.

All children begin to produce their own spontaneous songs at around 18 months, and experiment with musical intervals. Their spontaneous songs lengthen and develop in internal organization between two and three. However, by five, spontaneous singing declines in frequency, as the child becomes concerned with making mistakes, and shows an interest in imitating heard songs with accuracy (Sloboda, 1985). Thus, most children in Western culture stop generating music by the end of the preschool years. This decline in playful experimentation with song has its parallel in a decline of flavorful, pre-conventional drawings of the preschooler, and a concern for literalness in drawing in the elementary school years (Gardner, 1980; Winner, 1982).

Once again, musically gifted children tell a different story. Most musically gifted children learn to play an instrument, and soon after they begin to play they show 'musical generativity' in the form of improvising, and in transposing tunes to new keys. E. N. could transpose

pieces to new keys at seven, and by ten could transpose complex pieces into any key with ease. He could improvise by four and for the next three years he improvised more than he composed, both on his own themes as well as on those of others. Mozart improvised by four (Schonberg, 1970; Scott & Mofett, 1977). For other examples, see Richet (1900), and Walters, Krechevsky & Gardner (1985).

The ability to compose in early childhood is far rarer than the ability to perform, and these are clearly two separate kinds of musical talent (Persson, 1997). Revesz (1925) argued that a gift for composition is rarely seen before late childhood. J. S. Bach, Handel, Beethoven, Mendelssohn, Brahms are examples of great musicians reported by Revesz who were performing virtuosi in early childhood but who did not compose until early adolescence or later. E. N. is a rare example of a child who began to compose as early as 3½. Haydn, Mozart, Chopin, Mahler, Meyerbeer, Saint-Saens, and Strauss also produced their first compositions before 10 (Revesz, 1925; Radford, 1990). Mozart began composing at 4 and by 8 had already written six sonatas for piano and violin and three symphonies for small orchestra. However, the biographies of great composers show that the ability to compose at an early age is much rarer than the ability to interpret and perform music at an early age.

### *Multiple Representations of Musical Relations*

Musically gifted children have an unusual capacity for representing musical relations in multiple ways (Bamberger, 1986). Bamberger demonstrated this by comparing musically gifted children to three other groups: musically untrained (presumably non-gifted) children, musically untrained adults, and musically trained adults. They were given a randomly ordered array of bells that formed the pitches of the C major scale along with two Cs, two Gs, and two Es. They were asked to construct a familiar tune (Twinkle Twinkle Little Star).

Children and untrained adults always added new bells to the bell path in their order of occurrence in the tune; they never moved backwards to hit the same note a second time. Thus they needed two different bells for the two Gs in the tune, because each was heard as different. These non-gifted and non-trained individuals used what Bamberger (1986) calls a 'figural' strategy, because they focused on the figure of the tune and heard each note within the context of the tune's shape. Doing this leads to the two Gs being heard as different because of their different functions in the tune.

The non-gifted but trained adults used a 'formal' strategy (since they had received musical training), building a C major scale and then playing the tune on the scale as if it were a keyboard. They focused on the formal structure of the tune. In contrast, the gifted children switched strategies. At first they began with a figural strategy, lining pitches up from left to right. But

when they got to 'star', they switched to a formal strategy and moved backwards to hit the G already used for 'twinkle'. Thus they realized that one bell could be used for both. They felt a conflict between figural and formal strategies as they proceeded and made both figural and formal choices, showing that they represented the notes both in terms of their position on the C major scale and also in terms of their function within the tune. (Two notes can be identical yet serve a different function, and thus feel different.) Thus, Bamberger (1986) argued that musically gifted children have multiple internal representations for the same piece of music, and can move freely from one kind to another. While they are capable of formal strategies, they have also retained the capacity for a more intuitive figural approach. In contrast, non-gifted individuals, irrespective of age and musical training, use a single strategy and focus consistently on a limited set of musical dimensions.

A similar point has been made by Scripp and Davidson (1994), who showed that even musically gifted conservatory students face the challenge of developing and coordinating multiple representations of music. Scripp and Davidson found a lack of coordination between conservatory students' performance knowledge (their ability to play their instrument) and their understanding of musical notation, with the former often way ahead of the latter. For example, they found that conservatory students who have no trouble sightreading tunes on an instrument have considerable difficulty, and make many errors, if asked to sight sing. We should not, therefore, make the mistake of assessing musical development only by studying performance knowledge. Musical development is multi-dimensional, and musical giftedness does not develop at the same rate along all dimensions.

### *Expression*

Just as researchers have, we believe, focused too narrowly on realism as an indicator of giftedness in the visual arts, so also have they focused too narrowly on sensitivity to analytical and notational aspects of music—structure, themes, transformation—as the indicator of musical giftedness (Kirnarskaya & Winner, 1997). Sensitivity to non-notational, expressive properties of music—register, timbre, loudness, articulation, and phrasing—has been overlooked. These are the features that carry the emotional and dramatic message of music. An individual with a heightened expressive ear for music might not be able to follow the details of musical structure, but can hear and respond to the emotional message of the music. Persson and his colleagues (Persson, 1996; Persson, Pratt & Robson, 1996) found that musicians judged pieces in terms of their emotional response, that positive emotional experiences with music were one of the most important factors prompting them to become musicians, and that

emotional aspects of music were often ignored in traditional conservatory training. Perhaps sensitivity to the emotional message of music is a better indicator of musical giftedness than is sensitivity to notational aspects.

The Seashore measures (Seashore, 1938), as well as most other musical aptitude tests (e.g. Bentley, 1966; Gordon, 1987; Stankov & Horn, 1980; Shuter-Dyson & Gabriel, 1981), are based on the assumption that individuals with musical talent have an excellent 'analytical ear' for music. The Seashore measures assess analytical skills such as the ability to make fine differentiations between tones and musical structures. Individuals are asked to listen to pairs of chords, intervals, rhythms, and brief melodies and to decide if they are the same or different. Cultures in which children are selected for musical training rely on these same kinds of measures: children are given brief tunes and patterns to recall and sing back. The more accurate their performance, the more musical they are considered to be. (This, for instance, has been the practice of music schools in Russia for decades.) The core of musical aptitude is thus assumed to be the ability to detect pitch, duration of pitch, and rhythm.

Some psychologists have argued that musical aptitude tests should assess not analytic ability but rather other qualities that would be more closely predictive of high creative achievement in music. Davies (1978), for example, suggests that aptitude tests should assess musical reasoning. He argues that the possession of a sharp ear for music may be no more predictive of musicality than possession of good eyesight is predictive of good reading ability. Similarly, Teplov (1966) argued that musical aptitude should not be equated with having a good musical memory and an ability to differentiate chords and melodies. Rather, he argued, the ability to respond emotionally to music is the core of musicality. Teplov reflects the traditional Russian musicological interest in expression and affect in music, and in non-notational aspects of music making (Asafiev, 1947; Medushevsky, 1983).

Kirnarskaya and Winner (1997) found that most people, even those with high levels of music training, respond to music analytically rather than expressively. When asked to group passages of music, both trained and untrained individuals grouped according to analytic structure rather than expressive properties. Even music educators with high levels of music training grouped analytically. In contrast, concert performers, who had no more formal training than the music educators, grouped according to expression. Kirnarskaya and Winner concluded that formal musical training does not foster an expressive ear for music. Sensitivity to expressive properties may, they argued, be a marker for inborn musical giftedness. This suggestion, which remains to be directly tested, follows from the fact that concert performers grouped expressively, while equally well-trained music educators

(who are presumably less gifted since they did not become performers) grouped analytically.

### Origins of Artistic and Musical Gifts

#### *Practice*

The origin of artistic and musical giftedness is a subject of much debate. The lay person's view is that these gifts are innate (Winner, 1996a), and music teachers often say that they can tell right away when a student has inborn ability: these are the students who learn quickly, self-correct, and have high self-confidence when they perform (Walters, Krechevsky & Gardner, 1985).

Not all music educators subscribe to this nativist view, however. Perhaps the most famous exception was Shinichi Suzuki, the founder of the Suzuki method of music teaching. "Every child is born with the capacity for becoming richly musical so long as he or she is brought up properly . . . There is no inborn talent for music ability," wrote Suzuki (Herman, 1981, p. 36). Recently, some cognitive psychologists have developed this environmentalist position in the case of music, arguing that high achievement in music, like high achievement in any area, is due to hard work, perseverance, and what is termed 'deliberate practice'—goal-directed work on what is difficult (Ericsson & Faivre, 1988; Howe, Davidson & Sloboda, 1988; Howe, 1990; Ericsson et al., 1993).

The major problem with this environmental explanation is that there is no evidence that the hard work is causally related to high achievement (Torff & Winner, 1994; Winner, 1996a, b, 1998; Miller, 1999). It is just as likely that the intense motivation that leads prodigies (as well as savants) to work for hours at a time is due to the fact that they have high ability. Children are motivated to work hard at a domain in which they have special ability. But no typical child can be made to have a 'rage to master', and no typical child can be forced to work in the intense way that prodigies work. It is our position that hard work (or deliberate practice, in the case of domains in which one can reasonably talk about practice) is necessary for the development of any gift. But there is no evidence that hard work is sufficient, and thus no evidence to allow us to rule out an innate component to giftedness. Indeed, the strikingly early age of emergence of gifts in art and music, and the fact that high levels of skill make themselves known prior to formal training, are both strong pieces of indirect evidence for an innate component (Winner, 1996a, b).

#### *Family and Teachers*

Families of both artistically and musically gifted children tend to be supportive and encouraging, but families play a far more interventionist and active role in the case of the musically gifted (Csikszentmihalyi, Rathunde & Whalen, 1993). Without a supportive home environment, musically children often give up a musical instrument (Freeman, 1979). Almost all music

prodigies come from musical families (Scheinfeld, 1956; Scott & Moffett, 1977; Judd, 1988; Radford, 1990). Similarly, artistically gifted children almost always have parents or close relatives who are artists or in fields related to the arts (Feldman & Goldsmith, 1986; Gordon, 1987; Goldsmith & Feldman, 1989). Of course, we have no idea how many artistically or musically gifted children have been born into non-supportive families and whose gifts have hence never developed (Persson, in press).

Music prodigies who continue to perform and compose as adults are nurtured and even pushed by their parents and teachers. The gift is never fully developed when first observed, and must be nourished through daily training. Those who continue with music as adults all report having had at least one parent or teacher who cared deeply about their talent, and who worked with them daily, sitting with them as they practiced and establishing a structure of discipline. Studies of prize winning musical performers show the universal presence of at least one parent who was 'fanatically' interested in music and in the child's musical development (Bastian, 1994). The violinist Isaac Stern remarked, "There *has* to be someone pushing, a parent or a teacher. Every one of the kids I've guided has someone like that in their lives, pushing them, sometimes gently, sometimes horribly, sometimes, unfortunately, to the point of driving the child away from music. It's the quality of parental pushing that helps determine the eventual outcome of the prodigy" (Winn, 1979, p. 40).

The importance of a first music teacher who is warm and supportive has been noted by many (e.g. Sosniak, 1985; Bastian, 1994; Howe & Sloboda, 1991). Most adult musical performers eventually attend a conservatory to get musical training in a department of music. While musically gifted children typically enter a regimen of formal training at a young age, and stress the necessity of hard work and practice for the development of their talent (Bastian, 1994), artistically gifted children often get little formal training in art. At least in the West, artistically gifted children are often suspicious of formal art education, believing such tutelage to be unnecessary and potentially destructive of their talent (Gardner, 1980). The typical art class in elementary and high school does not serve to stimulate these children's art. It is a sad commentary on the way that art is typically taught in school that none of the sculptors studied by Sloane and Sosniak had anything good to say about their elementary or high school art classes. Winner and Pariser (1985) also noted this: the artists they interviewed reported that what crystallized their identity as young artists was some professional artist who noted their ability. Contemporary Chinese artists show the same negative attitude towards their elementary school arts instructors (Winner, 1989). Thus, family and community appear more important than schools in the development of artistic ability. Not

surprisingly, then, gifted children often make their best, most inventive work out of school (Hurwitz, 1983; Wilson & Wilson, 1976).

### **Relationship between Childhood Giftedness and Adult Eminence**

Highly gifted children often face a crisis at adolescence. Bamberger (1982) points out that prodigies in music experience a midlife crisis at adolescence, when they become increasingly critical of their playing, and this crisis often results in dropping out of music. The same situation may well be true of artistically gifted children. Adolescence is the time when prodigies must make the transition from technical perfection to innovation and big-C, domain creativity. Only those who can reinvent themselves will make the leap between childhood giftedness and adult creativity (Gardner, 1993). It is extremely difficult to predict those gifted children and prodigies who will make this transition, and those who will not (Simonton, 1994). We might predict that a six-year-old who can draw as realistically as a skilled adult will grow up to be the next Picasso. But again, if at twenty she is still just drawing with technical precision, and not doing anything innovative, she will begin to fade from public view. Take the case of Alexandra Nechita. She is famous now as a child for painting in the style of late Picasso. But will anyone take notice of her as an adult if she continues only to paint in the style of Picasso? Rostan et al. (1998) found that the childhood drawings of great artists (Picasso, Klee, Lautrec) were not distinguishable from drawings of contemporary gifted child artists. Yet surely few if any of this contemporary group will become great artists. Clearly, while high ability is necessary, it is not sufficient. Degree of skill in childhood cannot by itself predict later creative eminence; nor can early detection or the best and most rigorous course of training (Scripp & Davidson, 1994).

The situation is the same in music. A child who plays Mozart just like her teacher, or even just like a Heifetz recording, amazes us. But by twenty, if this prodigy does not play in a way that is new, with some deep understanding, and a new interpretation, serious musicians and critics will lose interest. Technical perfection will win a child adoration, but it will win the prodigy grown into adulthood little or nothing.

Almost all research on musical giftedness has limited itself to the study of children learning the Western classical tradition. We know little about the development of giftedness in the arena of Western popular or counter-cultural music, nor about the development of children in non-Western musical traditions. As pointed out by Persson (1995, 1997, in press), traditional Western conservatory training is highly competitive, stressful, inflexible, and places a strong value on conformity to tradition (see also Gelber, 1988; Kennedy, 1991). Is it not possible then

that such training may constrain the emergence of domain-altering creativity? Given the far greater emphasis placed on rigorous formal training for young people in music than art, the musically talented child in our culture faces very different developmental hurdles from those faced by the artistically talented child.

Great artists, especially music performers, were often prodigies as children (Shuter-Dyson, 1986). However, the reverse is not the case: most children who are gifted in art or music do not become adult artists, musicians, or composers. When discussing artistically gifted children, the art historian Hartlaub commented that the promise of these "over-potential years of childhood is almost never fulfilled in adulthood" (Lark Horowitz et al., 1973, p. 190). Even among those who weather this crisis and do not drop out, most do not become known as creative geniuses. This is not surprising, as there is no direct route from precocity to inventiveness. But of course a few prodigies do go on to change their respective domains. These are the ones who earn the epithet 'creative' or 'creative genius'. These are the individuals who, at adolescence or early adulthood, take a new stance. They begin to take risks: they challenge the establishment (Gardner, 1992, 1993).

One reason why only a few artistically and musically gifted children and prodigies make the transition to become domain creators as adults is that the funnel is small: there is simply not enough room at the top for all prodigies to become creators; and so there is an inevitable weeding out. Any domain would be in chaos if there were as many creative adult innovators as there are child prodigies.

A second inevitable reason is that the skill of being a prodigy is not the same as the skill of being a big-C creator. A prodigy is someone who can easily and rapidly master a domain with expertise. A creator is someone who changes a domain. It is likely that personality factors play a major role in becoming a domain creator. Creators are restless, rebellious, and dissatisfied with the status quo (Simonton, 1994; Sulloway, 1996); and they have something new to 'say'.

In a study of seven creative geniuses, Gardner (1993) suggests that a certain degree of tension, or 'asynchrony' is required for a prodigy to grow into an adult artist or musician who would be classified as creative, or even as a genius. Gardner (1992) argues that creative geniuses differ from prodigies in how well the individual synchronizes with his or her domain as it currently operates within the society. The prodigy typically exhibits talents that fit well with a domain that is recognized by the society as important, and the skills of the prodigy are thus instantly recognized. In contrast, the creative genius often initially exhibits talents that do not fully fit within the domain in which the individual works, and which do not fit with the

established tastes of the field (e.g. critics, gallery owners, conductors).

Of course, some individuals, such as Mozart, start out as prodigies and go on to become adults who transform their domains. As a prodigy, Mozart pleased the establishment. But it is only because of his later behavior, when he began to write music that we considered shocking, and which broke with established convention, that we now consider him to be a creative genius. The creative artist/musician takes risks, and breaks with conventions; the gifted child, or child prodigy, does not. As Hurwitz (1983) points out, gifted children have invested a great deal of energy in mastering a set of skills, and are often unwilling, or even unable, to experiment in the way that one must do in order to be creative.

Gardner's (1992) notion of asynchrony is compatible with Getzels and Csikszentmihalyi's (1976) notion of problem finding. In a study of art students, Getzels and Csikszentmihalyi found that the art students who went on to become recognized as creative artists did not differ from their art student peers in technical skill. Where they stood out was in their tendency and ability to find challenging problems. This problem-finding mentality is reminiscent of Picasso, who delighted in posing difficulties for himself which he could then go on to solve (Richardson, 1991). Even as a child, he fought against what came naturally, insisting on setting up difficult drawing challenges for himself such as beginning a drawing from an odd starting point, or drawing a profile facing right when the opposite orientation is more natural for a right-hander (Richardson, 1991). (For another example of a gifted child artist posing difficult challenges for himself, see Winner, 1996a, p.71).

Sheer hard work also plays a role in determining whether a prodigy becomes a creative adult artist or musician or composer. The personality characteristics associated with success in any field are drive, tenacity, and the willingness to overcome obstacles (Roe, 1953; Gardner, 1980; 1993; Simonton, 1994). "I believe in nothing but work," said Picasso, who had tremendous energy and drive (Richardson, 1991, p. 48).

Finally, historical and socio-cultural factors determine who becomes classified as an adult creator or genius. No individual or artistic work is inherently creative or not. Instead, creativity is an emergent property formed by an interaction among the individual's gift, the state of the domain at the time when the individual begins to exhibit talent, and the tastes and judgments of the field (e.g. critics, curators, publishers) (Gardner & Wolf, 1988; Csikszentmihalyi, 1988; Gardner, 1992, 1993; Pariser, 1992/93). There is a fair amount of serendipity involved in determining whether giftedness grows into creative genius. One needs to be born at the right time, at a time when the field is ready to recognize one's talents.

# Genius and Giftedness: Same or Different?

Dean Keith Simonton<sup>1</sup>

## Introduction

Lewis M. Terman's monumental *Genetic Studies of Genius* is universally recognized as one of the classics in the research literature on giftedness. Each volume of this multi-volume work holds significant insights about the development of intellectual giftedness across the life span. Yet it is also essential to recognize why the set of six volumes must be styled 'studies' rather than as a single 'study'. The plural designation is required because Terman's magnum opus actually contains two rather different kinds of empirical inquiries. On the one hand, the bulk of *Genetic Studies* is allotted to Terman's impressive longitudinal study of gifted children. These results are treated in Volumes 1 and 3 through 6. Published over a 70-year period, these volumes cover almost the entire human life span (Terman, 1925; Burks, Jensen & Terman, 1930; Terman & Oden, 1947, 1959; Holahan & Sears 1995). Of these volumes, it is Volume 5 that is in many respects the most crucial (Terman & Oden, 1959; see also Oden, 1968). This volume, which was published posthumously, attempted to prove that those whom he had identified as talented children did in fact become highly successful adults. The gifts of childhood could even become the genius of adulthood (see also Subotnik & Arnold, 1994; Subotnik, Kassin, Summers & Wasser, 1993).

Volume 2 contrasts greatly with the others. Published in 1926, this is the only volume of the first five that Terman did not co-author. This 842-page tome was instead written by Catharine Cox, one of his graduate students. She chose a rather different approach to the study of giftedness across the life span. Instead of identifying a group of gifted children and then following them through adulthood to determine whether they attained eminence in some achievement domain, Cox opted to reverse the strategy: She identified a group of clearly famous adults and then looked to the biographies of their early childhood to discover whether they had shown any signs of

giftedness. Hence, Terman's longitudinal investigation of children was complemented by Cox's retrospective investigation of adults. The explicit hope was that these two inquiries would corroborate each other. Gifted children would develop into geniuses, and the geniuses would eventually prove themselves to have been gifted children. It was this hope that led Terman to include this otherwise misfit study among the set.

But was this hope actually realized? Does giftedness necessarily transform into genius? If not, why not? And, on the other side of the coin, does all genius display giftedness in youth? If not, again, why not? Significantly, this is a problem that deeply concerned Terman himself. Not every one of his gifted children realized their supposed potential, and so he made a big effort to explain away these failures. Cox was also cognizant of this problem. Many of the 301 geniuses in her sample would not have been qualified for membership among the elite Termites, as they affectionately came to be called. This discrepancy she tried to handle in a number of ways. Thus, the linkage between childhood and adulthood talent may be more complicated than the main theme of *Genetic Studies of Genius* would have us believe.

I will therefore devote this chapter to discussing some of the developmental complexities. Taking full advantage of subsequent research on both giftedness and genius (e.g. Albert, 1992, 1994; Subotnik & Arnold, 1994; Winner, 1996; Simonton, 1997b), I will survey the principal agreements and disagreements that have surfaced in longitudinal and retrospective studies of talent development. In particular, I concentrate below on three critical topics: intellect, disposition, and development—questions that were explicitly or implicitly introduced in *Genetic Studies of Genius*.

## Intellect

Terman's children were specifically chosen according to their performance on the Stanford–Binet intelligence test, an instrument that Terman had himself developed just a few years previously. If a child earned an IQ score of 140 or better, he or she was considered sufficiently bright to be styled a 'genius'. In fact, the mean IQ score across the entire sample of more than

<sup>1</sup> Department of Psychology, University of California, Davis, USA. E-mail: dksimonton@ucdavis.edu

1,500 children was around 150, a rather impressive figure. IQ scores were also calculated for Cox's 301 geniuses, but in a necessarily different manner. Clearly the Stanford-Binet could not be administered to dead celebrities. Accordingly, Cox substituted a historiometric assessment for the psychometric. Because the intelligence quotient was then conceived as the ratio of mental age to chronological age (multiplied by 100), she and her collaborators—Terman among them—applied this definition to biographical data about the ages at which members of her distinguished sample demonstrated certain accomplishments. Actually, Cox was following a procedure originally developed by Terman (1917), who used this method to estimate the IQ of Francis Galton. In any event, her 301 geniuses also displayed a higher degree of intelligence, with IQ scores also averaging around 150 (prior to introducing the correction of data reliability).

Both Terman and Cox conceived of genius as a quantitative rather than qualitative characteristic. The more elevated an individual's IQ, the more impressive the talent, and hence the greater the magnitude of genius. Consequently, the IQ score should be strongly associated with a person's final accomplishments. It did not turn out this way. In the longitudinal study, not every intellectually gifted child grew to become an eminent adult. Even worse, differences in IQ could not discriminate between those who were successful from those who failed to realize their potential (Terman & Oden, 1959). The results were not much better in the retrospective study. Even though Cox found a small positive relationship between IQ and eminence, this correlation has been shown to be mostly artifactual (Simonton, 1976a). That is, the correlation shrinks to zero once the appropriate statistical controls are introduced. Later studies have arrived at similar conclusions for both psychometric and historiometric samples (e.g. McClelland, 1973; Simonton, 1984d; cf. Barrett & Depinet, 1991). Only a few studies have found that variation in intellectual ability can successfully predict the level of attained distinction (e.g. Simonton, 1986b, 1991a). So, why is it that adulthood genius is not always linked to childhood giftedness, as gauged by psychometric or historiometric IQ?

#### *Thresholds and Triangular Scatterplots*

Part of the answer comes from the fact that intelligence functions as a necessary but not sufficient basis for achievement. Below a certain IQ, the probability of adulthood success becomes minuscule. But beyond that threshold level, additional increases in IQ will not necessarily translate into proportional amounts of distinction (Guilford, 1967; Simonton, 1985a; Barron & Harrington, 1981). Admittedly, an exceptionally high intelligence *may* allow more accomplishments than a somewhat lesser intelligence (Benbow, 1992); it's just that there are no guarantees. In fact, the scatterplot describing the relationship between genius

and intelligence tends to be best described as triangular (Simonton, 1994). As intelligence increases, the highest possible level of attainment increases, but so does the cross-sectional variation. Hence, there can be extremely bright individuals who are no more successful than persons with IQs far lower.

#### *Curvilinear Relations*

Another phenomenon undermines the relationship even more: under special circumstances, an excessively high IQ can actually work to the *disadvantage* of a person. In the first place, unusual precocity may obstruct the development of the social maturity so essential to the emergence of an adult well-equipped for the rough-and-tumble world. Examples of intellectual prodigies who failed to actualize their potential for this particular reason are numerous. The classic illustration of this failure is William James Sidis (Montour, 1977). Furthermore, aside from social maturation, extremely bright persons often suffer many difficulties trying to convince others of the worth of their ideas. Too often the excessively brilliant will 'talk over the heads' of their audiences, and they thus can discover themselves dismissed by potential appreciators as unacceptably 'high brow', 'cerebral', 'theoretical', 'eccentric', 'radical', or 'avant-garde'. This liability is especially potent in those achievement domains in which success depends on the cultivation of a broad constituency. A mathematical physicist can afford to be understood by only a handful of experts; a politician, entrepreneur, commander, or religious leader cannot.

In fact, one mathematical model specifically predicts that for those areas of accomplishment where a person must appeal to the masses, the functional relation between IQ and effectiveness is curvilinear, with a maximum point around 119 (Simonton, 1985a). The predicted curve has been confirmed by an impressive body of psychometric and historiometric research (Simonton, 1994). Evidence for the model also appears in the Terman and Cox samples. Few Termites attained distinction in areas of leadership that required the ability to win popularity with the masses. And in the Cox 301, those who did attain fame in this fashion—such as the Presidents of the United States in her sample—displayed much lower IQs than did her other geniuses. Indeed, the lowest IQs were exhibited by the military leaders in the sample – individuals who must inspire confidence in the common soldier or sailor. Hence, it is possible to have too much of a good thing, so that a high IQ can be a bad thing.

#### *Multiple Intelligences*

In the early decades of the 20th century, psychologists were prone to view intelligence as a single, homogeneous construct. This coherence has even been given the name 'Spearman's *g*' to honor Spearman's (1927) advocacy of a unified, *general* latent variable under-

lying performance on all intelligence tests. Terman and Cox were not exceptions. Both implicitly believed in Samuel Johnson's (1781, p. 5) assertion that "the true Genius is a mind of large general powers, accidentally determined to some particular direction."

Nonetheless, research since Spearman, Terman, and Cox implied that intelligence may be a much more complicated construct than any single-factor theory can accommodate (Guilford, 1967; Sternberg, 1985). In Gardner's (1983) theory, for instance, at least seven distinct intelligences exist: verbal, logical-mathematical, spatial-visual, bodily-kinesthetic, musical, intrapersonal, and interpersonal (for more possibilities, see Gardner, 1998). As a consequence, there ought to be seven varieties of intellectual giftedness, as well as seven kinds of genius. In line with this inference, Gardner (1993) examined seven exemplars of each intelligence drawn from 20th-century celebrities: T. S. Eliot, Albert Einstein, Pablo Picasso, Martha Graham, Igor Stravinsky, Sigmund Freud, and Mahatma Gandhi. Even so, it is obvious that Terman identified giftedness and genius using an IQ test that is heavily slanted toward the first two or three of these seven intelligences. It should not surprise us, therefore, that most of his children became professors, lawyers, doctors, and scientists rather than artists, choreographers, composers, psychoanalysts, or world leaders.

Naturally, this problem still plagues many modern definitions of giftedness and genius. Children will still be chosen for gifted programs according to their performance on narrowly defined psychometric instruments. In addition, there are still people who identify themselves as 'geniuses' simply because they score so many standard deviations above the mean on some equally restricted measure. Hence, an IQ of 132 allows someone to join Mensa, an IQ of 164 is the entrance criterion for the Four Sigma Society, and an IQ 228 puts someone in the *Guinness Book of Records* as the world's brightest person (McFarlan, 1989). These views of talent exhaust one specific type of intelligence and unjustly exclude the many equally valuable forms that intellect may take.

Are the foregoing criticisms inconsistent with the results of Cox's retrospective study? After all, didn't she discover that eminent geniuses had extremely high IQs? However, it is critical to note that Cox's operational definition of IQ was actually rather different from Terman's. In gathering evidence of childhood and adolescent precocity, Cox did not impose a homogeneous, unidimensional conception of intelligence. Rather, she allowed each one of her 301 geniuses to decide the particular intelligence on which they would be assessed. J. S. Mill had his IQ gauged according to his phenomenal analytical precocity, whereas Mozart was evaluated according to his attainments as a musical prodigy. Cox's judges did not penalize anyone for being mediocre or even retarded in some cognitive domain captured by the Standford-

Binet. Hence, Cox's IQ scores were implicitly based on the thesis that there exist multiple intelligences.

#### *Skewed Distributions*

Terman and Cox, following Galton (1869), thought that intelligence was distributed like so many other psychological and physical characteristics. That is, IQ was believed to exhibit a normal distribution in any large population—the classic bell-shaped curve. For the most part, moreover, that belief was justified, at least as an approximation. Typically, IQ will be distributed so that about two thirds of the population will have an IQ within one standard deviation from the mean, and virtually the entire human population will have an IQ score within four standard deviations from the mean. For example, only one person out of a million can be admitted to the Mega Society, which requires an IQ of 176.

If intelligence has such a close connection with accomplishment, then the distribution of achievements should also be roughly described by the same bell-shaped curve. Yet that is completely false. The marked discrepancy in the distributions is best seen by looking at an objective measure of accomplishment, such as income, influence, or productivity (Price, 1963; Walberg, Strykowski, Rovai & Hung, 1984; Simonton, 1988a). Creative output offers a case in point. No matter what is the domain of creative behavior, the distribution of lifetime productivity is highly skewed, with a small proportion of the contributors producing the overwhelming proportion of the total products (Dennis, 1954a, 1954b, 1955; Simon, 1955; Shockley, 1957; Albert, 1975). This skewed distribution is so firmly established empirically that it has already become the source of corresponding behavioral laws (Lotka, 1926; Price, 1963). For instance, the Price Law holds that if  $k$  designates the number of creators active in a particular achievement domain, then  $\sqrt{k}$  provides the number of that select few who can be credited for *half* of everything contributed to that field (Price, 1963). A good illustration is found in classical music, where about 250 composers are responsible for at least one permanent contribution to the repertoire. So, the number of composers who should be responsible for half of that repertoire should be the square root of 250, or 15.8, which rounds off to 16. This is exactly the case (Simonton, 1984b). To indicate what this elitist disparity signifies more dramatically, assume that we translated this distribution into the same terms as IQ scores, labeling them *productivity coefficients* or PQ (Simonton, 1988c). Then the highest PQs would be almost 200 points higher than the highest recorded IQs! We often talk of geniuses as being giants in their fields. Well, imagine coming across a true giant whose height measures 21 standard deviations above the population average!

How can this conspicuous discrepancy between IQ and PQ be explained? There are many potential

explanations (Simonton, 1997a), but I want to consider just one long-standing explanation (Shockley, 1957; Eysenck, 1995). When we try to identify the predictors of some phenomena, behavioral scientists tend to think in terms of additive models. This means that each cause makes an independent contribution to the overall effect, the latter being simply the sum of the separate effects. Furthermore, should the diverse components be normally distributed in the population, any summation of those components will be similarly distributed. Yet outstanding talent could very well be a behavioral phenomenon in which the effects participate in a *multiplicative* fashion. All of the varied factors of exceptional attainment—intelligence, motivation, personality, developmental experiences and conditions, education, etc.—are multiplied together rather than merely added. Yet the multiplicative combination of normally distributed variables does not yield a normally distributed product but rather a composite variable with a highly skewed *lognormal* distribution (for demonstration and additional implications, see Simonton, 1999). This fits perfectly with what we see in distributions of lifetime accomplishments.

The same multiplicative model is compatible with the threshold and triangular distributions noted earlier. Persons who are very low on just one of the contributing factors will not manifest any gifts as adults. Zero times any number is zero. Accordingly, below the minimum intellectual requirement, we cannot expect genius to emerge. Yet additional increments in intelligence beyond the threshold requirement will not necessarily augment the odds for achievement. The contribution of the most exalted intelligence to the overall product can be negated by striking deficiencies in other components of the product. Indeed, this is precisely what occurred to those Termites who grew up to become adulthood underachievers. However impressive their IQs, some critical factor was missing from their personal makeup.

In comparison, other individuals with much lower IQs may compensate by having assets that enable them to achieve far more than the Termites. An example is William Shockley (Eysenck, 1995). As a child, Shockley was among the initial batch of children whom Terman tested for inclusion in the longitudinal sample. Yet his IQ was not high enough to certify him as a psychometrically established genius. So rather than become a gifted child, Shockley became a famous scientist instead, winning the Nobel Prize for Physics as co-inventor of the transistor. Not a single Termite received so high an honor. Obviously, Shockley had other virtues that helped him achieve despite his nominally 'sub-genius' IQ.

### Disposition

Cox was cognizant of the existence of such tradeoffs. After assessing the personality traits of a subsample of 100 geniuses, Cox noted that drive and determination

could more than compensate for a less than stellar IQ. Specifically, she confessed that "high but not the highest intelligence, combined with the greatest degree of persistence, will achieve greater eminence than the highest degree of intelligence with somewhat less persistence" (Cox, 1926, p. 187). This motivational facet of talent development is absolutely mandatory for success. High achievement demands an adult who can overcome the many trials and tribulations that dot the path to genius. Even after luminaries have established their reputations, their positions is never secure, and failures will follow successes throughout their careers (Simonton, 1977, 1985d, 1997a). Furthermore, to attain eminence in any field requires a childhood and adolescence packed with hard training and practice. Empirical studies have shown that potential talents must grapple with their domain several hours per day for a full decade before their latent capacity starts to become actualized (Bloom, 1985; Hayes, 1989; Simonton, 1991b; Csikszentmihalyi, Rathunde & Whalen, 1993; Ericsson, 1996). Such a massive commitment is not for the faint of heart. The members of the Cox sample who attained eminence notwithstanding mediocre intellects clearly had this mandatory quality in place. By the same token, those of the Termites who did not fulfill the original expectations often lacked this very requisite (Terman & Oden, 1959).

Dearth of enthusiasm and persistence is not the sole personality liability that may prevent a gifted child from transforming into an adult genius. The character profile necessary to attain greatness in maturity is very complex, requiring that a maturing talent be high on some traits and low on others (Cox, 1926; Cattell, 1963; Simonton, 1986b, 1991a; Eysenck, 1995). Yet this achievement profile is not what is always selected for whenever IQ tests provide the basis for identifying talent. The often-cited studies by Getzels and Jackson (1962) and Wallach & Kogan (1965) show this very well. Children chosen according to their high IQs tend to have personality profiles rather distinct from those who are selected according to their exceptional scores on tests that have a more direct claim to assess creativity. For example, the latter youths are prone to be more playful and humorous, to be less conventional in their life aspirations, and to be less conforming in their attitudes about their education and future careers.

But the most striking disparity concerns psychopathology. Terman (1925) collected data on his subjects' character traits in order to contradict the then-common opinion that genius was near to madness. Terman showed that his intellectually gifted children were certainly not abnormal. On the contrary, both psychologically and physically, the Termites tended to be well above the norms for the human population. Yet studies of eminent personalities reveal something rather different. These investigations have found support for Dryden's (1681, p. 6) famed dictum that "Great Wits are sure to Madness near ally'd./ And thin Partitions do

their Bounds divide.”

It would require too much space to review all the pertinent literature on this point, but that has already been accomplished by others anyway (e.g. Richards, 1981; Prentky, 1989; Simonton, 1994; Eysenck, 1995). It should suffice to offer the following four points:

(1) Historiometric inquiries find that famous achievers displayed incidence rates for various mental disorders that exceed the rates observed in the general population (Ellis, 1926; Juda, 1949; Martindale, 1972; Goertzel, Goertzel & Goertzel, 1978; Post, 1994; Ludwig, 1995).

(2) Psychiatric investigations encounter comparably high percentages of mental and emotional illnesses among distinguished contemporaries (Andreasen & Canter, 1974; Andreasen, 1987; Jamison, 1989).

(3) Psychometric research on eminent personalities have found that they often obtain high scores on the clinical subscales of several standard personality measures, such as the EPQ and the MMPI (Barron, 1969; MacKinnon, 1978; Götz & Götz, 1979a, 1979b; Rushton, 1990).

(4) Genetic analyses of family pedigrees reveal that notable adults are more prone to emerge from lineages that exhibit high proportions of psychopathology (Myerson & Boyle, 1941; Juda, 1949; Karlson, 1970; Andreasen, 1987).

These four forms of evidence seem to corroborate the conclusion that genius-grade talent may reside at the delicate boundary between healthy and unhealthy personalities. Moreover, we have cause for thinking that this delicate placement is not incidental. Certain advantages can actually accrue to personalities that teeter-totter on the edge of sanity.

Such persons are less conforming, more unconventional, even iconoclastic (Eysenck, 1995). Such individuals may experience manic episodes replete with optimistic activity that results in a large body of outstanding work (Jamison, 1993; Weisberg, 1994). Such personalities may also entertain crazy thoughts, bizarre associations, or strange metaphors or analogies that later enable them to arrive at landmark insights (Woody & Claridge, 1977; Eysenck, 1995). Naturally, all of these proclivities can also go too far, giving the poor soul too much of a good thing; those who inherit or acquire an inclination to advance beyond the frontier into fantasy land may never see their gifts mature into genius (Rothenberg, 1990). Or, like Van Gogh or Schumann, these sad personalities may not permit their talents to progress as far as they would have in the absence of suicidal disorder. Nevertheless, it's just as hazardous to talent development for a gifted person never to break out of the shell of conventional complacency.

It is very likely that Terman's sampling procedures are to blame for the dearth of high-grade genius among his Termites. Rather than test the entire student population, Terman relied on teacher nominations to

screen those students who their teachers thought had the most promise. How many kids were not so named because their teachers thought them more weird than bright? Furthermore, even if a few oddballs somehow got through this first filter, how many of them would have taken the Stanford-Binet with sufficient seriousness to provide answers indicative of their true intelligence? How many future geniuses would have had a diverting time offering humorous or Bohemian responses that would bring their scores down? Of course, we can never know, but is it possible that William Shockley was one of them?

### Development

A false impression may have been stimulated by the previous discussion. It was noted that the borderline pathology that enhances the realization of intellectual talent may be inherited, because notable personalities frequently come from pathological family pedigrees. Thus, the familial lines of 'natural ability' described by Galton (1869) appear to roughly parallel familial lines of 'unnatural abilities'. When two such genetic lineages just so happen to intersect in exactly the correct proportions, giftedness turns into genius. Nonetheless, this inference would not be correct. Genius is not just born; it is also made—by the environmental circumstances in which the youth develops his or her talent. Genetic endowment solely provides the raw materials from which environmental events and conditions can configure talent growth. At this point as well, we can isolate some interesting contrasts between potential and actual talents. Below I concentrate on three categories of environmental factors: (a) birth order, (b) traumatic events, and (c) education and training; these have probably received the most attention in empirical research (Simonton, 1987, 1994).

### Birth Order

Terman (1925) observed that first-borns were over-represented among his Termites. A like disproportion also appears to hold for child prodigies (Feldman & Goldsmith, 1986). Moreover, early investigations of adulthood genius suggested that primogeniture had the same advantage for them as well. The first such observation came from Galton's (1874) study of notable British scientists (see also Ellis, 1926; Albert, 1980). Nonetheless, later research indicated that birth-order's impact is more complicated. First-borns are more prone to achieve eminence in some domains, while other ordinal positions have the advantage in rather distinct domains. Hence, where first-borns become eminent scientific creators (Roe, 1952; Eiduson, 1962; Clark & Rice, 1982; Terry, 1989; Sulloway, 1996), later-borns become the artistic luminaries (Bliss, 1970; Clark & Rice, 1982). The main exceptions to this rule is that classical composers are more strongly aligned with the first-borns (Schubert, Wagner

& Schubert, 1977), whereas the scientific revolutionaries are more strongly aligned with the later-borns (Sulloway, 1996). A comparable pattern holds in leadership, where the first-borns are the source of status-quo politicians (Zweigenhaft, 1975; Wagner & Schubert, 1977), whereas the last-borns populate the revolutionaries (Stewart, 1977; Sulloway, 1996). Overall, a consistent pattern emerges from these data: First-borns tend to attain distinction in highly prestigious positions that are an integral part of the Establishment, whereas the later-borns are more prone to succeed as rebellious agents of a new order or even to serve as advocates of disorder.

We need not discuss the exact developmental foundation of this divergent outcome (but see Sulloway, 1996). The crucial point here is simply to note that we can now better understand why Terman's gifted children turned out so conventional. When first-borns predominate in a sample, we should predict a higher percentage of doctors, lawyers, professors, and other prestigious professions (Schachter, 1963), but a low percentage of artists, writers, revolutionaries, and others who are less willing to conform to societal definitions of success. Indeed, this developmental tendency may even explain why the first-borns were originally so prominent among the Termites. In the first place, first-borns may have been more inclined to seek the scholastic success that would have earned them a teacher nomination during the initial stages of the study. In addition, the first-borns may actually have been more enthusiastic about earning more conventional acclaim by performing so well during the IQ screening. Indeed, I wonder if the tendency for IQ to decline with ordinal position says more about attitudes than about aptitudes (cf. Zajonc & Mullally, 1997). The later-borns may have less respect for the authorities who unilaterally decide that these measures gauge something significant, and they may even prove too iconoclastic to accept the presumption that the test questions do in fact have a single correct response!

Whatever the upshot of the preceding speculation, one conclusion seems firm. Birth-order may not so much decide the magnitude of genius as the direction that genius takes (cf. Helmreich et al., 1980). To claim that first-borns are more successful because they enter prestigious occupations serves merely to perpetuate the first-born orientation toward talent development.

### *Traumatic Events*

Empirical inquiries into the origins of famous achievers repeatedly discover that a significant percentage suffered less than happy childhoods (Goertzel, Goertzel & Goertzel, 1978). Perhaps the family experienced substantial ups-and-downs in economic and emotional well-being, or maybe the home was the locus of tragic events. Of the various ways that misfortunes can visit a talent's youth, the one that has earned the most attention has been orphanhood or parental loss (e.g.

Albert, 1971; Eisenstadt, 1978). For both leaders and creators, the proportion of geniuses who lost one or both parents before attaining majority is noticeably larger than what appears to hold in the population at large or in any other relevant comparison group (e.g. Martindale, 1972; Berrington, 1974; Silverman, 1974; Walberg, Rasher & Parkerson, 1980; Berry, 1981).

These statistics become all the more intriguing when we contrast them with the much more benign home circumstances that the Termites enjoyed (Terman, 1925; Holahan & Sears, 1995). His children were more likely to experience comfortable, stable, intact family environments. In addition, the same positive home settings tend to favor the emergence of child prodigies (Feldman & Goldsmith, 1986). What does this discrepancy tell us?

Perhaps 'trials and tribulations' in the early years have a beneficial impact on talent development; the developmental advantage may have three causes that may operate either individually or in some combination (cf. Simonton, 1987, 1994):

(1) Traumatic events may disrupt standard socialization to such a degree that the youth will find it less likely to conform to societal norms and expectations. Parents play a big role in inculcating societal normals and values, both as instructors and as models.

(2) The youth may experience a bereavement reaction that plunges development into a lasting emotional equilibrium that can only be alleviated by the attainment of distinction (Eisenstadt, 1978); fame and fortune serve as remedies for the underlying emotional scars.

(3) The experience of traumatic events can facilitate the acquisition of an emotional robustness that helps the person accommodate all the disappointments and frustrations that attend the quest for success (Simonton, 1994). Those talents that grow up in more benign circumstances may be totally ill-equipped for the hardships that await them in early adulthood.

Whatever the explanation, some qualifications are in order; for one thing, any advantage gained from an unhappy childhood or adolescence depends on the achievement domain. For instance, even though rates of parental loss are higher among famous scientists than among the general public, the rates among literary creators are higher still (Berry, 1981); artistic creativity may demand more life turmoil than does scientific creativity. Moreover, the impact of traumatic events must be gauged against the personal resources that the youth has at his or her disposal. Juvenile delinquents and suicidal depressives may also exhibit high incidence of parental loss (Eisenstadt, 1978). Thus, there probably exists an optimal level of developmental stress for each youth. What might not be enough challenge for one developing talent, might be just the right amount for a second, and yet far too much for a third. Hence, the numerous eminent individuals who attained distinction *without* having to endure orphan-

hood may be those for whom only less dramatic tests of character were required.

The intricacies be what they may, it is conceivable that most of the Termites were not adequately challenged during the course of their early development. They too frequently appear to illustrate Dylan Thomas' ironic comment that "There's only one thing that's worse than having an unhappy childhood, and that's having a too-happy childhood" (Ferris, 1977, p. 49).

### *Education and Training*

Terman was proud of the academic successes of his gifted children; these intellectually bright youths tended to attain praiseworthy grades and to advance to higher degrees. Child prodigies also tend to make their first big splash in the news by their exceptional exhibitions of scholastic prowess. It is not rare to read about super-brains who entered high school at 10 and graduated at 11 with straight As—as well as full scholarships to Ivy League colleges.

Even so, when we turn our glance at those individuals who actually make a name for themselves in some achievement domain, the picture changes radically. In the first place, those who obtain excellent grades and scholastic honors are not necessarily likely to attain eminence in their chosen fields; the correlations are either zero or very weakly positive (Hudson, 1958; Hoyt, 1965; McClelland, 1973; Cohen, 1984). Consequently, examples abound of undoubted geniuses who proved themselves to be mediocre and even inferior students. Furthermore, the association between the magnitude of formal education and the realization of talent is not always unambiguous. This is quite evident from a reanalysis of the 301 geniuses in the Cox (1926) sample (Simonton, 1976a, 1983a). By plotting her eminence scores (from Cattell, 1903) as a function of formal education level attained, one gets a curious pair of functions. First, for leaders one obtains a strictly negative linear function, the most famous leaders tending to have the least amount of formal instruction. Second, for creators one gets an odd curvilinear function, an inverted-J curve, with a peak appearing in the last two years of undergraduate education. In neither case is achievement a positive linear function of the number of degrees acquired, and for both creativity and leadership talent development may actually undergo damage. Nor is this result peculiar to the Cox 301, for comparable results have been found in more contemporary samples of adulthood achievers (Simonton, 1984b, chap. 4).

Naturally, it is one thing to discover an interesting empirical relationship, and another to comprehend its actual meaning; but one obvious possibility should be considered: Formal education may not always make a positive contribution to the growth of talent, and in certain cases it may actually inhibit the development of talent. On the one hand, those who hope to become lawyers, doctors, professors, and other academically

certified professionals certainly have little choice but to advance up the ladder of degrees; these were the attainments that predominated among the Termites. On the other hand, most artistic creators, revolutionary scientists, and other forms of unconventional achievement may have more to lose than to gain by going all the way to the highest available academic degree. Such creative activities may require just enough training to master certain basic knowledge and skills, but beyond that requisite, increased inculcation into more specialized disciplinary preoccupations may only interfere with more crucial endeavors. For example, success in many achievement domains is conspicuously linked with voracious and omnivorous reading, an undisciplined exploration of ideas that may suffer under intensified academic pressures (McCurdy, 1960; Simonton, 1984b). Furthermore, many achievement domains demand the gradual acquisition of rather specialized techniques that are not always taught—or taught well—in formal academic settings. Whatever the specifics, we must remember that it normally requires about 10 years of intense dedication to master the materials of a field. As a consequence, whenever formal schooling is not making a direct contribution to the needed mastery then it is necessarily retarding the acquisition of that expertise. Distaste for that interference inspires many talented youth adults to become college dropouts—to their gain and society's too.

If a growing talent must obtain an education beyond the educational system proper, one type of extracurricular training is particularly valuable: mentoring. This was not a matter that attracted the attention from either Terman or Cox. Yet research on talented youths demonstrates that this is a critical factor in the emergence of their special capacities (e.g. Bloom, 1985; Feldman & Goldsmith, 1986; Arnold & Subotnik, 1994). The talented youth must encounter an appropriate teacher who is well equipped to cultivate the youth's current capacity, and often the talent must change teachers as that capacity grows. Moreover, retrospective investigations into famous adults reveal the importance of this same developmental factor, but with some crucial contrasts that are usually ignored in the longitudinal literature (Simonton, 1983b, 1992b).

(1) Mentors can have a detrimental effect on talent development if they are motivated to clone themselves through their students. In part, it is for this cause that it is usually more advantageous to experience multiple mentors rather than lean heavily on just one (Simonton, 1984a, 1992c).

(2) The linkage between mentor characteristics and talent development is often complex, with interaction effects, curvilinear functions, and other causal complexities (Simonton, 1977, 1984a, 1992c). For instance, the most accomplished mentors are likely to be those who are at the peak of their own careers rather than those who are past their prime, and thus who may be less receptive to new ideas.

Lastly, it is also essential to note that a growing talent may receive appreciable benefits from rather more impersonal relationships with predecessors who are active in the same domain. Role models of exceptional achievement may be admired and emulated at a distance long after those paragons of excellence have died. This indirect role modeling can frequently be every bit as potent as personalized instruction (Simonton, 1975, 1984a, 1988b, 1992c). Einstein had the portraits of three deceased predecessors hanging in his home study—those of Newton, Faraday, and Maxwell. These three luminaries probably had much more impact on the emergence of Einstein's special gifts than did any of his teachers.

Conceivably, many of the Termites failed to grow up to become highly gifted adults simply because they failed to form the right linkages with those predecessors who embodied the best in their chosen domain of achievement. In the absence of an intense ambition to surpass these predecessors, even the most prodigious gifts will seldom convert into even the most mediocre genius.

### Conclusion

In this brief space I could do little more than to provide an overview of what I consider a very profound puzzle. Many critical issues have been necessarily overlooked. I made no mention, for example, of the difficult question of how the adulthood realization of latent talents may differ for women and minorities (see, e.g. Vaillant & Vaillant, 1980; Helson, 1990; Tomlinson-Keasey & Little, 1990; Ochse, 1991; Simonton, 1992a, 1996, 1998; Arnold, Noble & Subotnik, 1996). Nor have I examined the matter of how the 'spirit of the times' (*Zeitgeist*) affects the growth and manifestation of adulthood achievement (e.g. Simonton, 1976b, 1976c, 1978, 1980; Martindale, 1990). And, finally, I have omitted discussion of the potential impact of crystallizing experiences, cultural and professional marginality, socioeconomic class, religious affiliation, and many other potentially crucial developmental factors (see, e.g. Lehman & Witty, 1931; Roe, 1952; Roe, 1952; Datta, 1967; Simonton, 1977, 1984c, 1986a; Walberg, Rasher & Parkerson, 1980; Berry, 1981; Walters & Gardner, 1986; Gardner, 1993). Nonetheless, those topics that I did cover should communicate the tremendous complexities in the process by which potential talent is converted into actual talent. We are a long way yet from comprehending all the factors that affect talent development. We are farther still from understanding how all of these factors intersect and interact in the emergence of the exceptional adult achiever. Further theoretical and empirical inquiries must attempt to consolidate all of these complicated forces and functions into a single, coherent, life-span developmental system. Besides encompassing the immense inventory of relevant developmental inputs, this system must accommodate

all the interaction effects, curvilinear functions, and other causal relations that moderate the impact of these influences. Moreover, this systematic account must address what I view as two absolutely essential questions:

(1) Why do so many gifted children fail to realize their potential upon becoming adults? What are the places where the developmental trajectory is most likely to veer off target? What are the most common blind alleys? This is the problem of the 'nipped bud'.

(2) Why is it that many highly successful adults managed to display no clear signs of giftedness in their early years? Does the developmental trajectory for these unpromising youths differ in some qualitative manner from that which guides the precocious child to adulthood achievement? This is the problem of the 'late bloomer'.

If we could understand the developmental foundations for both the nipped bud and the late bloomer, we would have a much more firm idea about how best to intervene in the growth of talent—especially within our educational systems, where society's involvement is most direct and potent. Thus, we might learn how to prevent the promising youth from going astray, and we might grasp how to accelerate the flowering of a latent talent. Moreover, at a more theoretical level, we would comprehend why not all of Terman's children became geniuses, and why not all of Cox's geniuses would have qualified as gifted youth. A comprehensive theory of talent development must encompass both ends of this significant phenomenon.

### Acknowledgments

This chapter is based on a keynote address delivered at the 1997 World Conference of the World Council for Gifted and Talented Children held in Seattle, Washington. I would like to thank Rena Subotnik and Robert J. Sternberg for their comments on an earlier draft of the chapter.

# International Trends and Topics of Research on Giftedness and Talent

Kurt A. Heller<sup>1</sup> and Neville J. Schofield<sup>2</sup>

## Introduction

During the last two decades a change has been taking place in the concepts of giftedness and talent as they are featured in research literature. Whereas until fifteen or twenty years ago the field was dominated by one dimensional giftedness concepts and corresponding IQ measurements, a large majority of more recent models are based on multidimensional or multifactorial psychometric concepts of intelligence—e.g. Gardner's (1985) theory of multiple intelligences—or on approaches from information theory and cognitive psychology—e.g. Sternberg's (1985) triarchic intelligence model. Other models still include elements from socialization theories, e.g. Mönks' (Mönks et al., 1986) extended Renzulli model. Furthermore, we agree with Sternberg's demand that (1990, p. 96): "We need to think in terms not only of multiple components of giftedness, but (also) of multiple kinds of giftedness". 'Giftedness' is thus defined as the individual cognitive and motivational potential for—as well as social and cultural conditions of—achieving excellent performances in one or more area/s such as in mathematics, languages, or artistic areas with regard to difficult theoretical vs. practical tasks (Heller, 1989, 1992). 'Talent' can be defined as a domain-specific gift or ability, e.g. 'scientific ability' as the competence for scientific expertise in the fields of psychology, medical sciences, or physics. However, the differentiation suggested by Gagné (1985) between 'giftedness' and 'talent' is infrequently maintained in the literature. In many languages—as in German—both concepts are used more or less synonymously. For this reason, no semantic differentiation was insisted upon in this handbook between 'giftedness' and 'talent'. When this makes sense in individual cases, the differentiation is explicated in that context. This also holds true for related terms, such as intelligence, creativity, or (high) ability, that are not independent of the theoretical basis

in which they are found. In addition, the definition of giftedness, etc. is dependent on the intended use, for example, on the type and tasks of school programs, the aims of enrichment vs. acceleration programs, on empirical investigation goals and theory-based hypotheses, etc. Moreover, the term 'giftedness' or 'talent' is influenced by social norms and considerations (Tannenbaum, 1983). Last but not least, the definition of giftedness will be determined by the choice of measurement instruments, i.e. by the operationalization of the experimental variables examined.

A differentiation between descriptive and explanatory terms is also relevant when looking at research strategies. Whereas the *descriptive* term is linked to the psychometric paradigm, the *explanatory* term needs an experimental design in the cognitive science paradigm. For example, on the one hand, the psychometric intelligence structure theories enrich the ability phenomenology substantially, while on the other hand, the cognitive psychological (experimental) studies make it possible to explain the mechanism of cognitive processes and their individual sources. This also corresponds to the various identification strategies: status vs. process diagnosis (see Part III of this handbook). Both descriptive and explanatory terms are necessary for theoretically and practically efficient conceptualizations and measures.

## Information Sources for the Data Analysis of Recent Research on Giftedness and Talent

The state of the art of research on giftedness and talent to be presented here was based on content analyses of the following *conference proceedings*:

- (a) the last three published volumes of proceedings from the World Council for Gifted and Talented (WCGT) in 1991, 1995 and 1997; cf. Mönks and Peters (1992), Chan, Li & Spinks (1997), Leroux (1998);
- (b) the until now published three volumes of proceedings from the European Council for High Ability (ECHA) between 1992 and 1996; cf. Heller and Hany (1994), Katzko and Mönks (1995), Spiel (1998);

<sup>1</sup> University of Munich, Germany.  
E-mail: heller@mip.paed.uni-muenchen.de

<sup>2</sup> University of Newcastle, Australia.  
E-mail: ednjsc@cc.newcastle.edu.au

(c) the previously published four volumes of proceedings from the Asia-Pacific Conferences (APC) between 1990 and 1996; cf. Roldan (1992), Wu, Kuv & Steeves (1993), Cho, Moon & Park (1995), Munandar and Semiawan (1997).

Proceedings for the first two ECHA Conferences in Zurich, 1988 and in Budapest, 1990, have not been published, nor have those for the 1993 WCGT Conference in Toronto. Those wishing to review the findings of the content analysis of the previously published nine volumes of proceedings from the WCGT Conferences held between 1975 and 1991 should refer to Heller (1993), Heller and Menacher (1992).

Furthermore, six major journals in the field (d–i) and two journals as a ‘control group’ (j–k) have been content analyzed over the last seven years (1992–1998):

- (d) Gifted Child Quarterly (GCQ);
- (e) Roeper Review (RR);
- (f) Gifted Education International (GEI);
- (g) Journal for the Education of the Gifted (JEG);
- (h) High Ability Studies (HAS);
- (i) Exceptionality Education Canada (EEC);
- (j) Exceptional Children (EC);
- (k) Journal of Educational Psychology (JEP).

The chapters and articles are classified according to seven categories:

- Learning and perception
- Identification
- Development
- Personal characteristics
- Physical/mental conditions
- Education and instruction
- Social issues.

Consequently, the various information sources can be evaluated with respect to corresponding vs. contradictory trends. We begin with an analysis of the conference proceedings (a–c). In addition, the WCGT Conference proceedings in the 1990s can be compared with those published in the volumes dating back to

1975 since the findings here corroborate those in the first edition of the Handbook (Heller, 1993). Furthermore, the structural concept of this handbook was included in the content analysis for comparative purposes. Supplementary to this, psychological sub-disciplines as well as the differentiation between research vs. practice-related reports are used as categories.

### Content Analysis—International Conference Proceedings

A total number of 163 manuscripts were published in the WCGT conference proceedings 1991–1997 of which approximately 38% were data based contributions; while a total of 95 manuscripts were published in the ECHA conference proceedings 1992–1995 with exactly 60% being data based contributions. Again, a total of 162 manuscripts were published in the APC proceedings 1990–1996, of which about 44% were data-based. Relatively speaking, the highest percentage of data based studies are to be found in the ECHA conference proceedings, and the lowest percentage among the WCGT conference proceedings. One must also remark that the percentage of data-based investigations in the WCGT conference proceedings in the past decade has risen by 13% with respect to the previous 15 years, namely from 25% (1979–1989) to 38% (1991–1997), a result which is pleasant indeed.

Significantly more modest differences are to be found for the three conference groups (WCGT, ECHA, APC) with respect to the age groups investigated (where middle age groups dominate in comparison with primary and pre-education groups as well as adults—the one exception being the European ECHA conferences). However, all three conference groups have common ground regarding the sample sizes of the data based proceedings in that a sample size of  $n = 501$  or more is rather seldom found (see Table 1).

Further agreement is maintained regarding methodological aspects. With approximately 80%, the interview is clearly the preferred measurement technique whereas the use of research designs—with one or two exceptions—show no large differences among the three conference groups (Table 2). Gratifying is the rela-

Table 1. Age Groups and Sample Sizes in the Data Based Contributions to the WCGT (1991–1997), ECHA (1992–1996), and APC (1990–1996) Proceedings.

Age groups:	WCGT	ECHA	APC
preschool	9.3%	3.0%	6.5%
primary education	7.8%	10.6%	16.3%
elementary/secondary education (grades 4–8)	26.8%	27.3%	30.4%
later secondary education (grades 9–12)	18.7%	19.7%	22.8%
higher education	21.8%	15.2%	13.1%
adulthood	15.6%	24.2%	10.9%
Sample sizes: $n =$ under 100	47.3%	52.9%	37.1%
$n = 101–500$	35.2%	29.5%	33.3%
$n = 501$ and more	17.5%	17.6%	29.6%

Table 2. Measurement Techniques and Research Designs of the Data Based Contributions to the WCGT (1991–1997), ECHA (1992–1996), and APC (1990–1996) Proceedings.

Measurement techniques:	WCGT	ECHA	APC
interview	80.6%	85.5%	78.8%
observation	9.6%	5.5%	7.5%
(quasi) experiment	9.8%	9.0%	13.7%
Research designs: single-age group	34.4%	29.1%	10.9%
cross-sectional	24.3%	34.5%	51.6%
longitudinal	41.3%	36.4%	37.5%

tively large percentage of longitudinal studies which in the WCGT proceedings was, with 10%, significantly higher than during the earlier period (1975–1989). For a detailed comparison of individual changes in the WCGT proceedings articles within the past decade in contrast to the previous 15 years see Table 3 (age groups and sample sizes) and Table 4 (methodological aspects).

What sorts of trends develop regarding research topic or subject group? The most important results of our proceedings content analysis are illustrated in Figs 1 to 4, which are also presented as conference group comparisons.

It becomes apparent that the categories 'Educational/Instructional Processes and Programming' in the WCGT conference proceedings 1991–1997 with a median of 43.5% (the corresponding figure for the period 1975–1989 was 35%) and 'Personal Characteristics' with a median of 30.5% (previously 25%) have

the most entries, relatively speaking (see Fig. 1a). One quickly notices that WCGT proceedings contributions concerning 'Development' (6%) and 'Identification' (3.5%) are only seldom occurrences, while the category 'Social Issues' is well represented with 11.5% of the contributions.

By contrast, in the European gifted conferences (ECHA), the individual categories are more balanced. Contributions in ECHA proceedings (1992–1996) most frequently concern the topic 'Personal characteristics' (37%), followed closely by 'Educational/Instructional processes and programming' (32.5%). The third most addressed topic here is 'Identification' (10.5%). Only slightly fewer contributions concern 'Physical/mental conditions' (8.5%), while 'Development' and 'Social Issues' are each covered in 5.5% of the contributions (see Fig. 1b).

The topic profile of the APC proceedings (Fig. 1c) proves to be largely similar to the WCGT conference

Table 3. Age Groups and Sample Sizes in the Data Based Contributions to the WCGT Conference Proceedings—Comparison Between the Period 1975–1989 and the Period 1991–1997.

Age groups:	(1975–1989)	(1991–1997)
preschool	3%	9%
primary education	13%	8%
elementary/secondary education (grades 4–8)	45%	27%
later secondary education (grades 9–12)	23%	12%
higher education	3%	22%
adulthood	13%	15%
Sample sizes: $n$ = under 100	42%	47%
$n$ = 101–500	42%	35%
$n$ = 501 and more	16%	18%

Table 4. Measurement Techniques and Research Designs of the Data Based Contributions to the WCGT Conference Proceedings – Comparison Between the Period 1975–1989 and the Period 1991–1997.

Measurement techniques:	Period (1975–1989)	(1991–1997)
interview	71%	80%
observation	5%	10%
(quasi) experiment	24%	10%
Research designs: single-age group	23%	35%
cross-sectional	67%	24%
longitudinal	10%	41%

profile described above. With about 53%, the category 'Educational/Instructional processes and programming' is even more frequent. All in all, however, the structural agreement among all three profiles in Fig. 1 (Figs 1a, 1b, 1c) is larger than the individual differences depicted.

This picture does not change much if we redefine the categories somewhat. If one prefers to use the structural concept from this handbook, then we find the

division as shown in Fig. 2—with comparisons of WCGT, ECHA and APC in Figs 2a, 2b, 2c.

The following analysis results are very informative regarding the psychological sub-disciplines which contributed to the three different conference proceedings (Fig. 3). There is a clear dominance of conference articles regarding Educational Psychology: 62.5% in the WCGT (Fig. 3a), 44% in the ECHA (Fig. 3b) and 62.5% in the APC (Fig. 3c). Although Personality

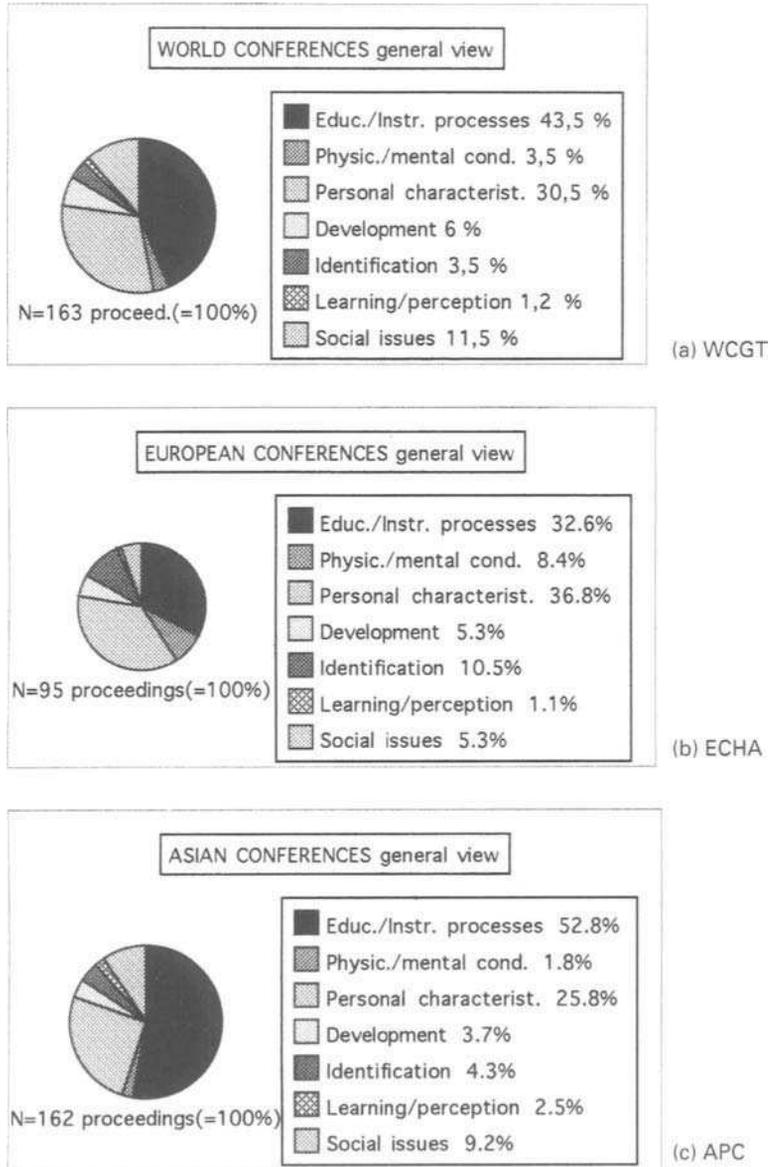

Figure 1. Content analysis of the WCGT conferences (1991–1997), the ECHA conferences (1992–1996) and the APC (1990–1996) proceedings: Percentages of the main topics.

Psychology makes up 25% of the proceedings in the WCGT and 26.5% in the APC, this topic is more frequently addressed in Europe (ECHA) with a share of 42%. The analysis of the WCGT proceedings in the time period between 1975–1989 resulted in a figure of approximately 70% regarding contributions which stem from Educational Psychology. On the other hand, topics relating to General Psychology were poorly represented by contributions (0.6% for both WCGT and APC proceedings and 1.1% in the ECHA proceed-

ings). Even when one takes into account that a stray basic research study could be hidden among the other categories (primarily in Personality Psychology), this finding can only be considered as disappointing from a research perspective.

This impression is confirmed in the following analysis results presented in Fig. 4. With theoretical contribution levels of 10% (Fig. 4a) to 20% (Fig. 4b)—with 14% the APC (Fig. 4c) lies in the middle—and only 0.6% (WCGT, APC), and 4.2% (ECHA) for basic

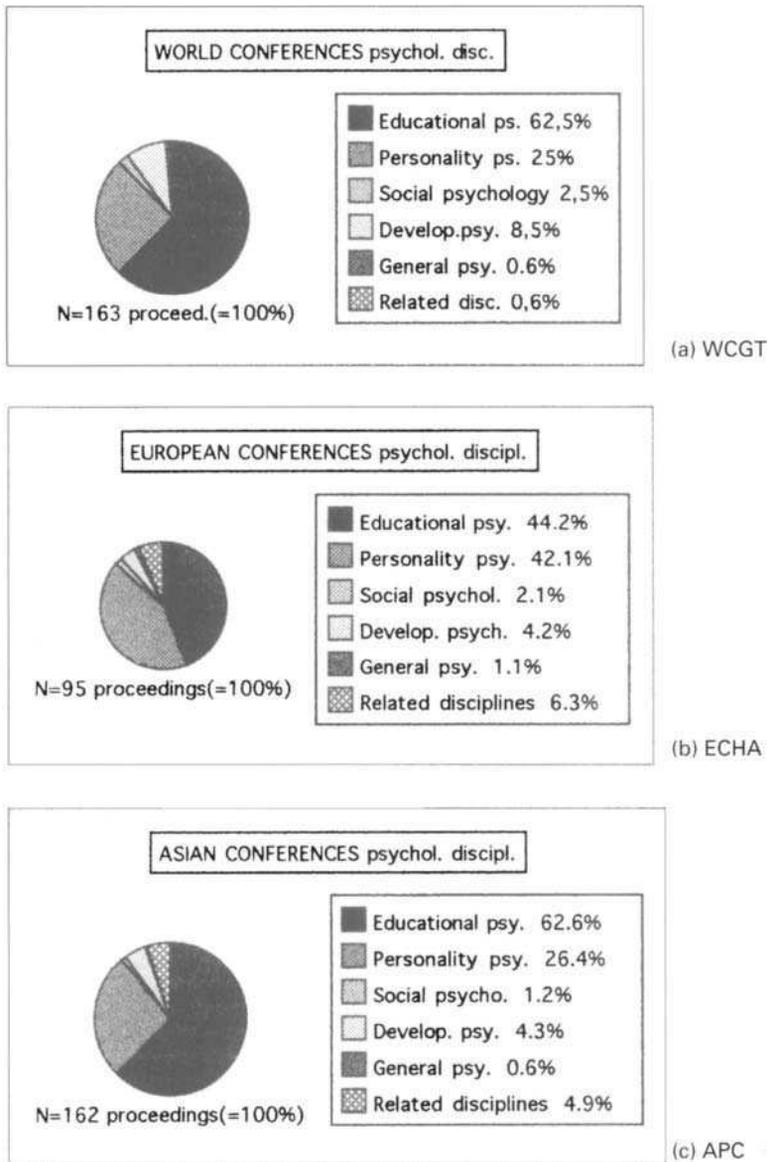

Figure 2. Percentages of the main topics of the WCGT conferences (1991–1997), the ECHA conferences (1992–1996) and the APC (1990–1996) proceedings according to the structure of the International Handbook.

(mainly experimental) research, these two areas are placed in direct contrast to data-based (empirical) studies, in the sense of applied research, shown to be 38% in Fig. 4a (WCGT), 45% in Fig. 4b (ECHA) and 36% in Fig. 4c (APC). This indicates a twofold increase in data-based research contributions for the WCGT proceedings for the last ten years in comparison to the preceding 15 year period (38% vs. 20%) whereby a simultaneous drop in the number of practical needs reports could be confirmed (18% vs.

40% previous). Real research contributions, i.e. those based on hypotheses made up approximately one quarter of all conference papers in the period 1975–1989. This level has made a gratifying increase in the past ten years in that about one third of all conference contributions now meet the usual scientific standards of applied research.

Further breakdowns regarding current research trends and topics can be expected in the content analysis of eight leading journals in the field. The

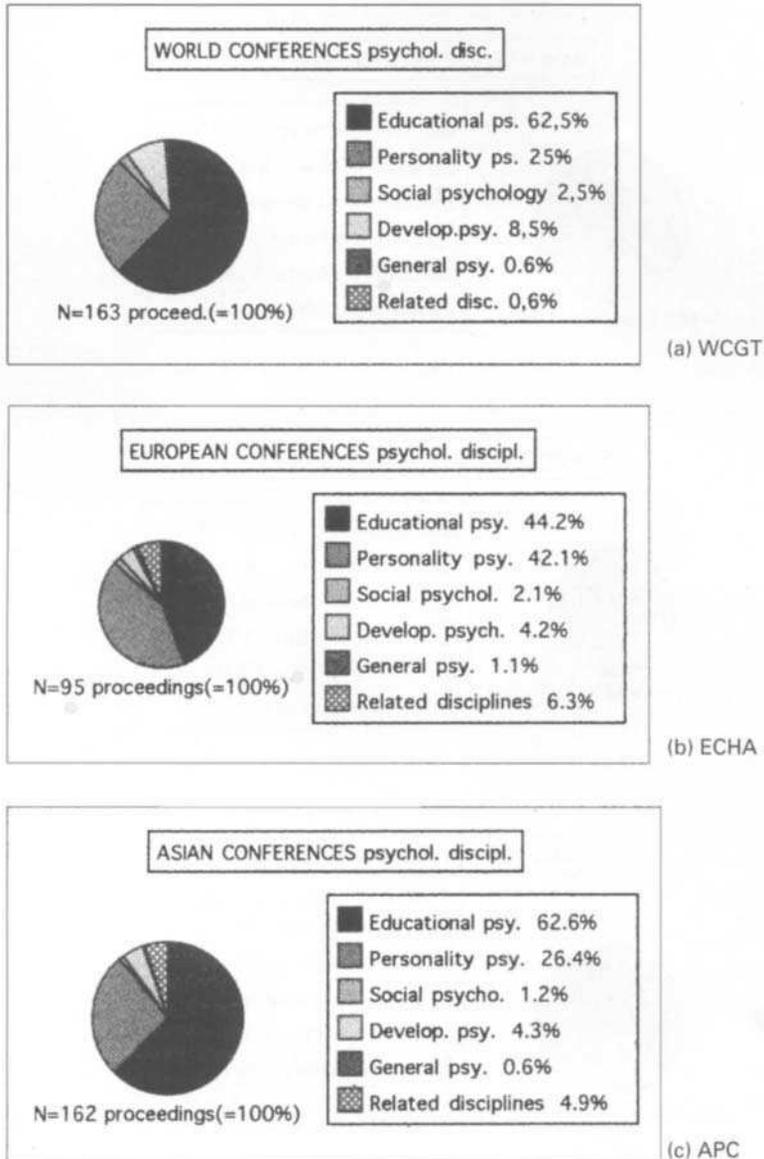

Figure 3. Classification of the papers published in the proceedings of the WCGT conferences (1991–1997), the ECHA conferences (1992–1996) and the APC (1990–1996) according to psychological subdisciplines.

results of this analysis will be presented in the following section.

**Content Analysis—Major Journals**

In the following section a content analysis of eight of the most important journals in this area of giftedness over the last seven years (1992–1998) is undertaken. The aim of such an analysis is to both consider the nature of the research currently being undertaken in terms of the general content headings of this handbook,

and to compare the results of such an analysis with those undertaken in the first edition of this handbook (Heller, 1993, pp. 51–56) some seven years ago. The eight journals analysed included the six used for the first edition: *Gifted Child Quarterly* (GCQ), *Roeper Review* (RR), *Gifted Education International* (GEI), *Journal for the Education of the Gifted* (JEG) as well as *Exceptional Children* (EC) and *Journal of Educational Psychology* (JEP) which were used as a ‘control group’, along with *High Ability Studies* (HAS)

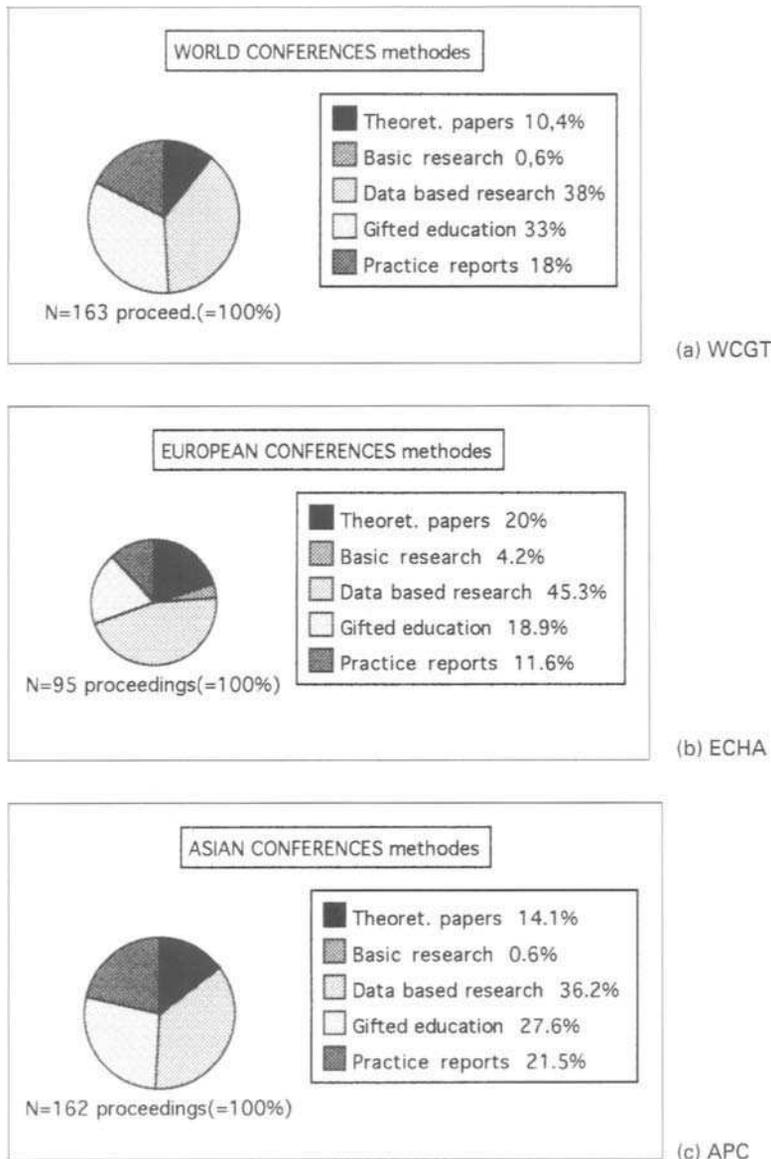

Figure 4. Classification of the papers published in the proceedings of the WCGT conferences (1991–1997), the ECHA conferences (1992–1996) and the APC (1990–1996) according to research vs practice reports.

[formerly *The European Council Journal for High Ability* (ECHA)] and *Exceptionality Education Canada* (EEC), also used as part of the control group. In particular, the analysis was concerned with:

(1) the nature of the topics most frequently addressed in those journals which deal with giftedness related research;

(2) relative differences between the five gifted journals in terms of their content and approach as well as the differences between the gifted journals and the control group in terms of the types of articles presented;

(3) whether, during the last seven years, there has been a shift in content, methodology or editorial approach, as reflected in the types of articles published.

In an effort to address these questions, the various journals were categorized along a number of dimensions, some of which overlap but each of which provides a theoretical framework which accords with a generally accepted view of either psychological or gifted research. In each series of analyses, all articles were categorized into one, and only one category, which inevitably resulted in relatively fine distinctions having to be drawn. In the first series of analyses undertaken on the five specified gifted journals (see Fig. 5), articles were categorized according to a generally discipline based formula, which revealed that there had been marked changes in the pattern of articles published in these journals since the previous analysis. Most notably, there was a decline in the number of articles devoted to 'Education and Instruction' so that, whereas previously up to 60% of articles fell into this category (in GEI), the highest percentage now found was only 41% (in RR). There was almost no change in the second most frequently reported category of article, namely 'Personal Characteristics', which meant that the decline in the first category resulted in a greater breadth in the nature of the articles published. Perhaps the greatest general spread of articles was to be found in the HAS, which was previously not included in the analyses. The category which was least represented was 'Physical/Mental' aspects of giftedness, mainly due to the very low representations in both the GCQ and the RR. Given that these are probably the two most prestigious journals in the North American group, one is forced to question why this category of research should be so scantily recognized. Another, somewhat related area, is that of 'Development', which was also poorly represented across the board. In particular, RR and JEG each had around 3% of their articles in this category, while the other three journals varied between 8% and 10%. It is impossible to tell from these analyses whether the low or changed figures given represent specific editorial policies or changes in general research interest. However, it could be assumed that the decline in representation across all five journals for articles related to 'Education and Instruction' does

represent a change in research interest over the period in question and the broader diversity which filled the void also suggests a more balanced approach to gifted research.

The second set of analyses, which is found in Fig. 6, corresponds to the general conceptual structure of this Handbook. This meant that, whereas in the First Edition 'Concepts and Development' was a single category, these two dimensions, which are conceptually discrete, are also separated in the analysis.

In all five journals the most frequently represented category was 'Programs and Practices', with percentages ranging from 26% (GEI) to 48% (JEG). This represents another shift in emphasis from the earlier analysis, where there had been a slight emphasis in favour of the area of 'Nurturing' (which largely involved Counseling of the gifted). This shift was particularly marked in JEG and, to a lesser extent, in the RR and GEI. The two categories of 'Concepts' and 'Development' were marked by a slight rise in overall percentages of articles with the area of 'Concepts' receiving greater numbers in all but one (JEG) of the journals. The predominance of the 'Programs and Practices' category accords with the similar importance of the 'Education and Instruction' category in Fig. 5.

When the articles are classified according to psychological sub-disciplines (Fig. 7) there appears to be a dramatic shift from the earlier analysis which cannot easily be explained. In the previous analysis, the dominant category in all four journals was that of 'Personality Psychology', with figures ranging from 55% to over 80%. However, in the present analysis in those same four journals this category is hardly represented and instead the category of 'Educational Psychology' accounts for between 69% and 78% of all articles. While an initial reaction might be to decide that this is a clear case of faulty classification, the situation is actually made more confusing by the fact that the newest journal to be added to the group (HAS) reports some 61% of articles as coming from the area of 'Personality Psychology', which suggests that there may have actually been a major editorial shift in the four original journals over this period. Indeed, a relatively quick scan of these earlier journals suggests that, while there may have been some minor evidence of misclassification, the figures were generally correct, which only leaves a significant editorial shift as an explanation, particularly as it seems that such personality research is still being undertaken, given the number of articles published in HAS. One possible alternative explanation is that, since the HAS is largely focused on Europe and the other journals reflect more of an American and international focus, the change in emphasis reflects a cultural shift in research activity.

Overall then, given the size of the imbalance, it is not surprising that there are very few other sub-disciplines which are significantly represented in these analyses. Certainly, it could be argued that the very broad

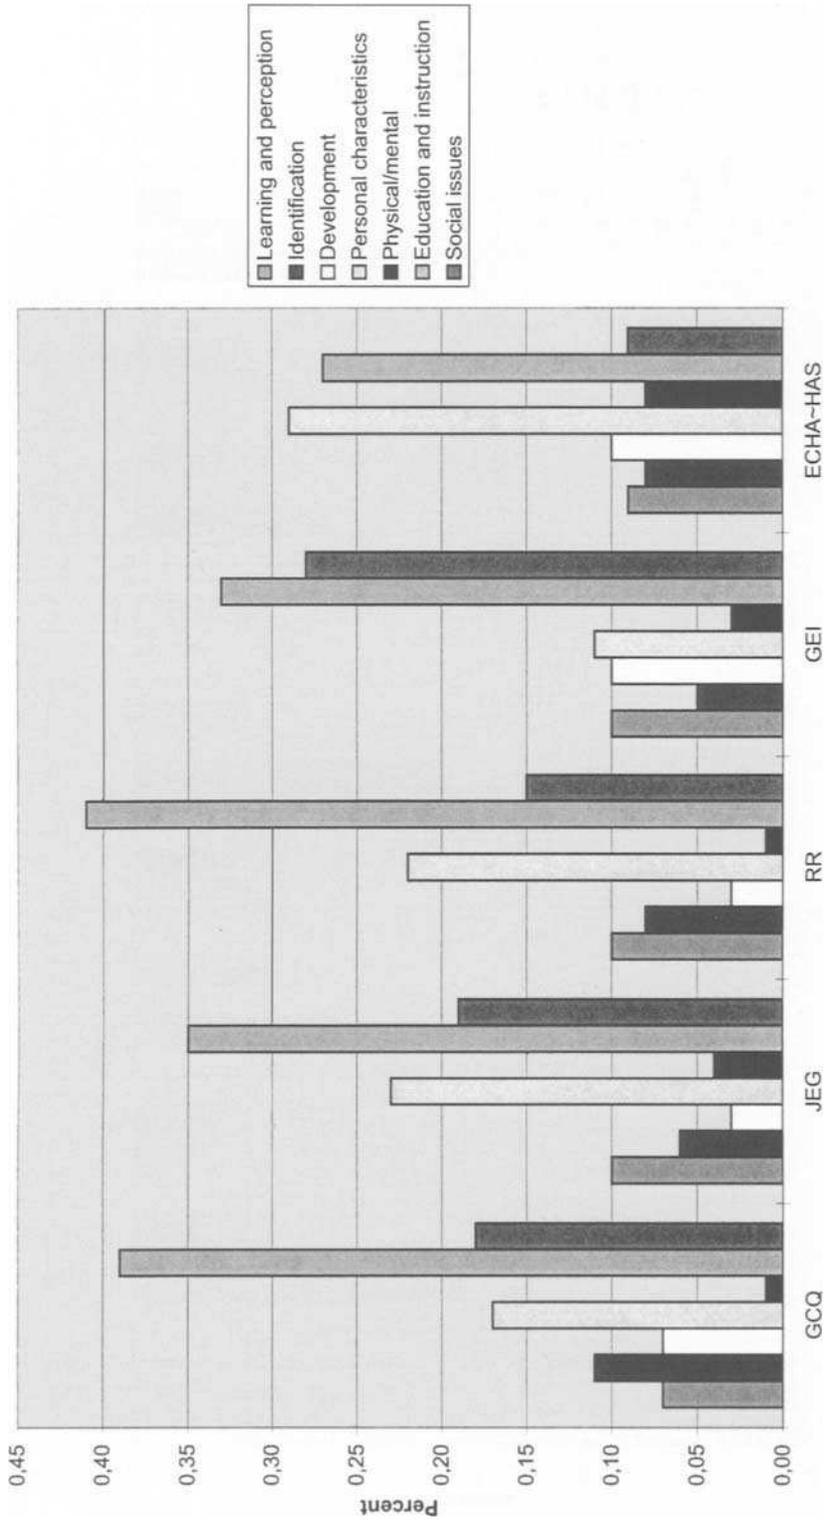

Figure 5. Percentages of the main topics in the five analyzed gifted journals (1992-1998).

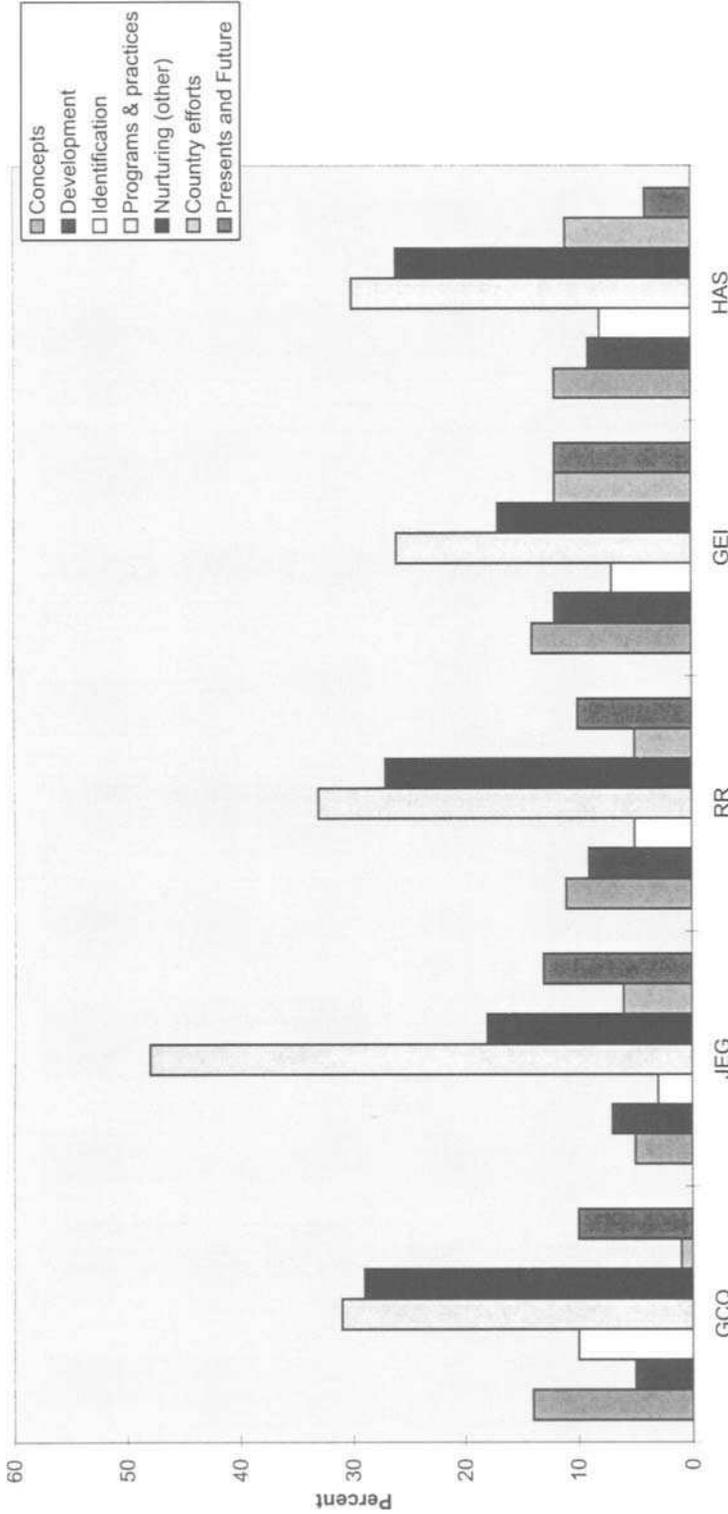

Figure 6. Percentages of the main topics in the five analyzed gifted journals according to the structure of this international handbook (1992-1998).

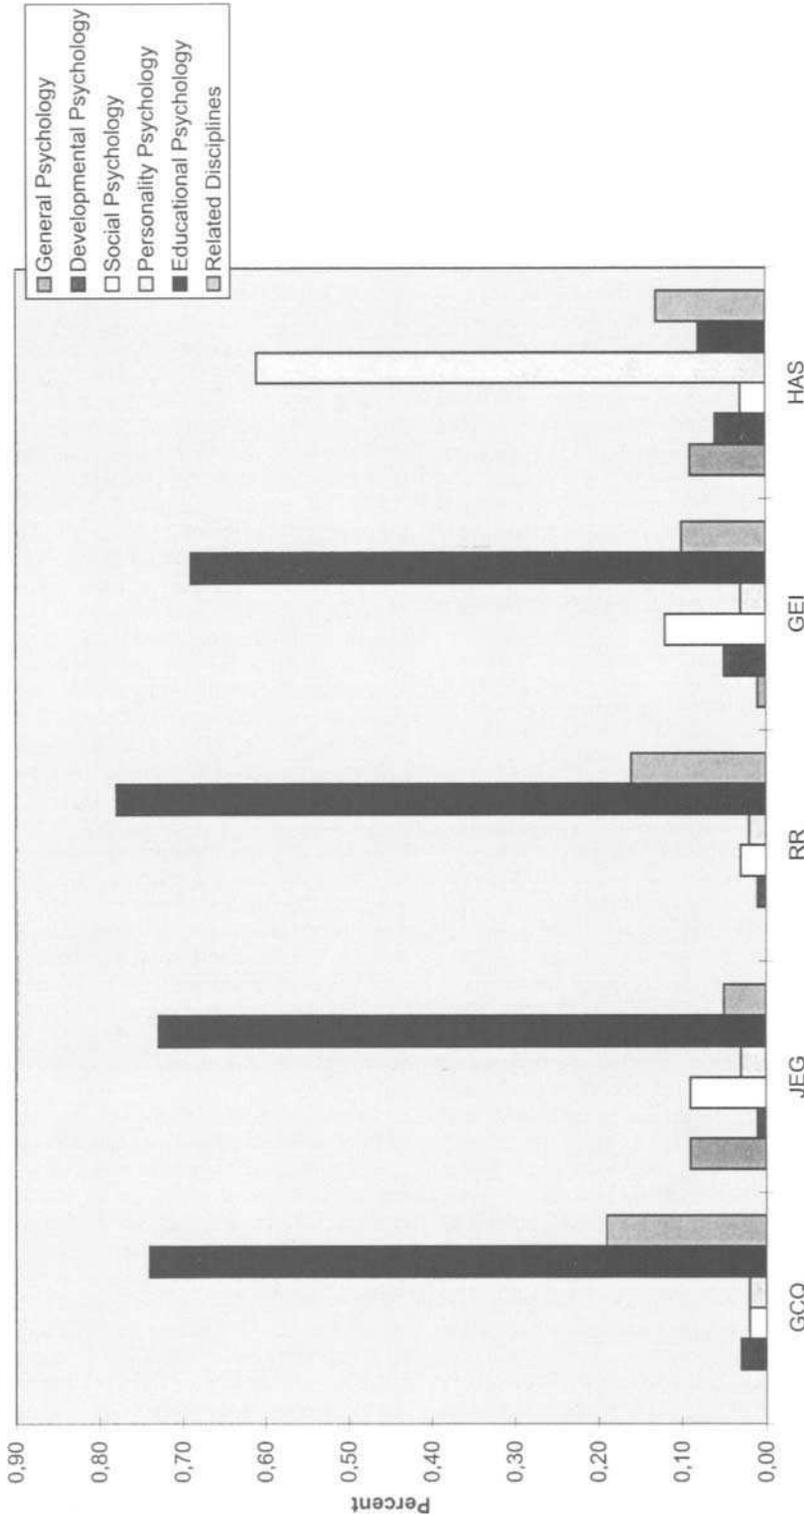

Figure 7. Classification of the articles published in the five (1992–1998) analyzed gifted journals according to psychological subdisciplines.

category of Educational Psychology is likely to be the province of most of the research on giftedness and this appears to have been reflected in all journals except for HAS. However the question remains as to whether there has been such a major shift in research emphasis in the non-European countries or whether there is some other factor at work here. If there has actually been such a shift in focus, then it perhaps should be a matter for some concern that researchers, both non-European and European, are not conducting research on giftedness in the broader areas of psychology in greater numbers. At the same time, if it is that researchers are actually undertaking the research into the broader areas of psychology but their work is simply not being published because of an editorial policy which has as its focus what the editors believe is the current fashion or perhaps even a belief about what *should* be the direction of giftedness research, then this is even more disquieting.

In an analysis of articles according to research methods and practice, the five gifted journals were compared with each other and with the three journals used as a control group (see Fig. 8). The dimensions which were considered were:

- theoretical papers
- basic research focused papers
- applied research (data-based studies)
- gifted education
- practical reports.

Amongst the five gifted journals there were definite variations in emphasis. One area of interest was the fact that GCQ and RR contained very little basic research, while the other three contained considerably more, with HAS reporting 28% of its contributions from this area. A lack of basic research was identified as one of the areas of concern in the previous content analysis and it is surprising that both the GCQ and RR have not reflected the changes that have emerged in the other three journals. This may also suggest that there is still a lack of good quality basic research being undertaken in the area of giftedness *per se*. Indeed, without such basic research, the very nature of giftedness is still open to question.

One other surprising result was that HAS had a relatively low percentage of articles devoted to gifted education (8%), especially when compared with GCQ (39%) and GEI (47%). Again, one must assume that this is a reflection of editorial policy. The final major difference between the five gifted journals emerged in the area of data-based (applied) research. Four out of the five reported figures of between 20% (JEG) and 37% (GCQ) whereas GEI reported only 4% of papers which fitted into this category. These figures represent 23% of all studies reported in these journals, which is a much lower proportion than that which was found in the earlier analysis (Heller, 1993, p. 53) where this category represented approximately 30%. It is

extremely disappointing that the area of gifted research is still so poorly served by both basic research and data-based research and that the warnings sounded so long ago in the Marland Report have not been heeded. Indeed, these figures suggest that the situation is actually deteriorating.

When a comparison is made between the gifted journals and the three control group journals, a number of other patterns emerge. In particular, the number of data-based studies is completely out of proportion to that reported in the gifted journals, with JEP reporting 89% of articles from this category, while EEC, which is the most recent entrant to this field, reports the lowest number from the control group with 37%, but this is still equal to the highest level of this category reported in the gifted journals. This is another reminder that the field of gifted education is decidedly out of step with the main body of research in educational psychology.

It is also sobering to note that in the more broadly based JEP, gifted education does not achieve any real prominence with only 2% of articles falling into that category. There is little difference in the other two journals which purport to focus on all exceptional children, with EC only reporting 3% and EEC 7%. The question must then be asked as to why gifted education assumes such a low priority in the general realm of education. Certainly it highlights the need for the maintenance and support of those specialist journals which devote themselves to this area. However, it also reinforces the possibility that gifted education has little of relevance to say to the rest of the world of psychology and that it largely exists in isolation. Consequently, one should also consider whether it might not be more appropriate for gifted journals to broaden their fields of interest so that they become relevant to other aspects of psychological research so that the journals have a wider appeal and relevance, rather than to just those who are focused on establishing giftedness as a discipline. Certainly, if these figures are any indication, the rest of the psychological world hardly notices the existence of giftedness research at all.

Another surprising result was the very low numbers of basic research articles published in the control group journals, with EC reporting none at all and JEP only 4%. In view of such figures, it may be that the low numbers commented on earlier for this category in GCQ were actually in line with the more general trends as shown in these other more broadly-based journals. There were also differences between the three control group journals in the area of theoretical papers, with JEP reporting only 5% in this category and EEC reporting a huge 48%. It appears from these figures that the more prestigious journals are less likely to publish theoretical papers and more likely to publish papers which are data based. However, given this trend, it is still surprising that more papers in the area of basic research are not published, which leads to the

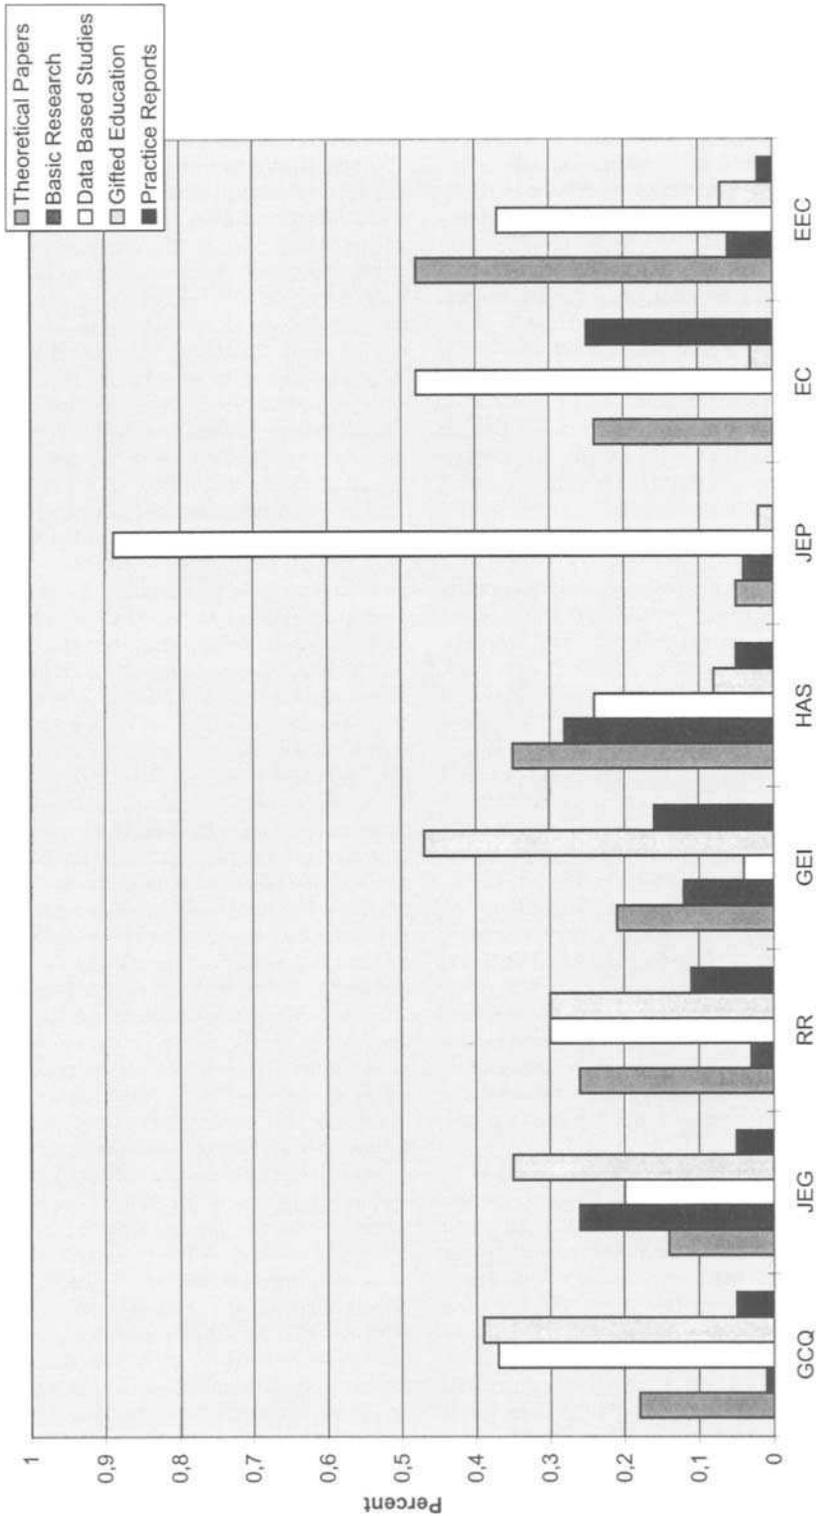

Figure 8. Classification of the articles published in (eight) analyzed journals (1992–1998) according to research and practice.

conclusion that there is very little basic research of sufficient quality for publication being undertaken.

In summary, these findings indicate that there has been relatively little change in most areas of gifted research in the last seven years, with the notable exception of a shift away from a focus on Personality Psychology within the non-European journals to an emphasis on Educational Psychology. There is still a general emphasis on the practical problems associated with gifted education and very little emphasis on research which is of a basic nature or which relies on an understanding of the psychological theories underpinning gifted performance. This was an issue which was highlighted in the earlier analysis (Heller, 1993) but, like most warnings of this kind, the concerns have fallen on deaf ears. Given the power of journal editors to shape research directions, as evidenced by the various changes in direction of a number of journals over the last seven years, perhaps these cautions should be specifically directed towards them.

### Conclusion

When one compares the content analysis results of the two sections—the conference proceedings and the field journals—the similarities between the two are considerable, although some distinct differences do exist. The greatest area of agreement relates to the *topics of main emphasis*, of which 70% to 80% stem from Educational and Personality Psychology contributions. In these categories applied research questions and methods outweigh those of basic research (cf. Figs 1 and 3) by more than 90%, a fact which has recently been criticized by Persson (1999). Few contributions from the category of *General Psychology* are to be found in either source (conference proceedings or gifted journals), although the greatest preponderance from this category can be found in HAS and JEG (cf. Fig. 7) with nearly 10%.

Preferred *age groups* are school-aged children and youth (cf. Table 1), with a growing number of data-based contributions to the (WCGT) conference proceedings (Table 3) emphasizing early adulthood age groups (higher education). *Sub specie methods* the empirical studies dominate with around 80% using descriptive (interview) measurement techniques as compared with 10% explanatory (quasi) experimental studies (cf. Table 2). *Sample sizes* up to 500 occur most frequently (Table 3). There has been a gratifying increase in longitudinal studies in the WCGT proceedings during the period from 1991–1997 (41%) when compared with the period 1975–1989 (10%). When compared with this earlier period, the level of cross-sectional and longitudinal designs remained constant in the 1990s (from 35% to 36% for the ECHA conference proceedings). In the empirical papers of the APC, however, cross-sectional studies continue to outweigh longitudinal designs with 52% and 38% respectively (Table 2). This could be interpreted as being the result

of different economic and/or historical circumstances for longitudinal studies in East Asian vs. European and North American countries.

Gifted journals generally do not differ from one another greatly in their *topic profiles*. The one exception to this is in the area of ‘social issues’ which, with 15–20% being reported in North American gifted journals, contrasts with the European journal HAS which reports approximately only half this rate of entries. Unlike the North American journals, the HAS reports ‘personal characteristics’ as having the highest rate of entries, although many of these do not fit into the psychological sub-discipline of ‘social psychology’. Indeed, the classification of all articles according to psychological sub-disciplines highlights the differences between the North American journals, which concentrate on Educational Psychology, and the European journal HAS, where Personality Psychology topics dominate with 60%.

If one compares the findings of the gifted journals with those of the so-called control group journals (JEP, EC, EEC), one notices—especially with JEP—the predominant role of data-based studies within the control group. Yet within EEC (which perhaps should have been included with the gifted journals), the ‘theoretical papers’ category dominates (48%), followed by data-based studies at 37% (cf. Fig. 8). This same percentage (37%) of data-based studies can be found in the gifted journal GCQ, followed by RR (30%), HAS (24%), and JEG (20%).

On the whole we can deduce that, aside from singular positive changes (for example the partial increase in longitudinal studies or the stronger observance of the adult age group), the 90s have contributed no more exciting qualitative changes to the research field than the past decades. However, this conclusion is valid at this point in time and only for the documents evaluated here, with the added proviso that the analyzed sources of information can be viewed as adequately representative of the entire research scene in the field of giftedness and talent with a focus on gifted education. There exists, however, no obvious reason for this not to be the case, so that perhaps the following summarized deduction may be allowed.

Despite the obvious quantitative increase of applied research activities in the field of giftedness and talent worldwide within the last decade, the topics of main emphasis, as well as the preferred research methods, apparently do not differ dramatically from those documented in the first edition of this handbook (Heller, 1993, pp. 49–60). In this respect, the 1993 (pp. 61–62) formulated list of desiderata *mutatis mutandis* remains valid. Parallel developments can, however, be observed in related disciplines (social sciences), so that we should not be too disappointed in this regard. Advances in knowledge can often only be achieved through small steps and extensive efforts in long-term research. To this end, an increase in the quality of

research designs and measurement techniques, including data analysis, is necessary. But most importantly, basic research in the field of giftedness and talent must be improved, which requires the intensification of cooperation with researchers. This is particularly true within the areas of 'General and Personality Psychology' and 'Cognitive Science' (where basic experimental research traditionally holds a higher priority); for greater detail see Waldmann & Weinert (1990). In general, a stronger emphasis on interdisciplinary research—above and beyond the boundaries of the strongly pedagogical-psychological dominated field of research—is essential in order to discover more about the nature of giftedness and talent. Julian Stanley's assertion is as valid now as before, that in the meantime we know quite a bit about the 'whats', but very little about the 'whys' of high ability, etc. To change this should be the top goal of researchers within the field of giftedness and talent during the first decade of the new millennium.

### Acknowledgments

The authors would like to thank Lea Salis and Jeffrey Reeves for their valuable assistance with data analysis.

# Developmental Psychology and Giftedness: Theories and Research

Franz J. Mönks<sup>1</sup> and Emanuel J. Mason<sup>2</sup>

## Introduction

Human development is generally regarded as an interaction between individual characteristics and environmental conditions. Historically, psychologists have debated whether development of an individual is determined more by organic or environmental factors. This nature–nurture issue is not only a concern for developmental psychology (Vernon, 1979). Education and socialization depend largely on theories and findings of developmental psychology. If proponents of the nature position predominate at a given time, human development is regarded as a process of maturation. If, however, the advocates of nurture are prevailing, the emphasis is on learning. Nowadays most developmental and educational psychologists hold a position somewhere between the two extremes.

The primary question in developmental research on the gifted is no longer whether nature or nurture is the most basic, but rather what is the kind of interaction that occurs between the two, and how this influences development. In other words, the results from the interaction of specific individual genetic attributes and experiences in a given social and cultural environment is the central concern.

Major developmental theories will be presented in this chapter. These theories will be related to conceptualizations and definitions of giftedness. The main intention is to elaborate on the contribution of developmental theories to our understanding of the gifted. Finally, teaching, instruction and educational reforms in gifted education will be discussed from a developmental perspective. In the present chapter, the authors treat the terms gifted, highly able, and talented synonymously.

## Developmental Theories

The concept of development includes a complexity of processes and their organization. This complexity is

constructed from conceptual and empirical elements. A theory of development depends on the accentuation of aspects of this complexity. Theories are most meaningful when they enable description, explanation and prediction of diverse phenomena (Mason & Bramble, 1997). It has been suggested that the usefulness of a theory of giftedness should be established in terms of what it implies about the nature of the gifted child, education and programs for the gifted, its structure and framework, and the criteria of good theory (e.g. logical consistency, parsimony) (Cohen, 1988). According to Marx (1963), a distinction is necessary between four different modes of theory construction. They are arranged from relatively more conceptual to relatively more empirical.

*Deductive theory* refers to any logically or deductively arranged cluster of concepts. The empirical data are explained from a conceptual structure. Such a formally organized theory can give direction to research but findings contribute little to produce a new or better theory.

*Functional theory* refers to the interaction of empirical findings and conceptualization. Empirical and conceptual activities are emphasized and have equal status in theory construction.

*Inductive theory* refers to the kind of theory that is essentially a summary of empirical data; it contains a minimum of deductive logic. Essentially it is the contrary of a deductive theory.

*Model* is a term for any conceptual analog that can be used for empirical research. Such an analog is often of a mathematical or physical nature. A model that directs the process of finding an answer or solution is called a heuristic. The result of such a process can be a hypothesis and as such contribute to a better conceptualization. Models often have a descriptive or explanatory function. Such a model accentuates the most important aspects. For example, the machine or deficit model has often been used to explain the human aging (i.e. the functioning of a machine decreases over time, parts of the machine getting old, which affects the

<sup>1</sup> University of Nijmegen, The Netherlands.

E-mail: monks@psych.kun.nl

<sup>2</sup> Northeastern University, Boston, Massachusetts, USA.

functioning of the system). This increasingly poorly functioning model serves as an analogy for the human aging process. Thus, a model has value as a heuristic or tool. A model is not subject to the same kinds of rigorous demands for verification and falsification as a theory (Cook & Campbell, 1979).

Developmental theories can be grouped by their different perspectives. Divergent orientations will be presented to show the variety of explanations for human development. Sometimes theories cannot be easily classified into these groups because they came from multiple perspectives, e.g. Sternberg (2000) is working from a functional and inductive perspective, in his model.

### *Biologically Oriented Theories*

In this context development is viewed as synonymous with evolution. Human development is mainly seen as growth and maturation of the organism, as unfolding of predispositions: i.e. heredity and temperament. In this view development is biologically determined. The environment plays a relatively unimportant role providing only the necessary ground for the growth of predispositions, comparable to a plant that needs favorable environmental conditions for its growth. Actually, development is a continuation of the genesis of the embryo.

Terman believed to his 'dying day' that intelligence is a genetically determined trait that is stable over the life of an individual (Minton, 1988, p. 199). However, by the time he was 77, his own empirical genetic studies, the longest developmental investigation in terms of duration ever attempted, convinced him that many of his 1500 subjects had never made use of their superior ability. He concluded that factors other than intelligence, such as personality and environment, determine in an essential way whether or not an individual reaches 'life success' (Terman, 1954). Nowadays, there are no serious proponents of this kind of theory. However, the relationship of genetics to behavior is currently an active issue among researchers as will be shown later in this chapter (e.g. Thompson and Plomin in this volume, Plomin, 1995).

### *Ecology-Oriented Theories*

Learning and sociologically oriented theories belong to this group. The influence of the environment on the development of a person has a central position in these theories. Human development is seen as an ongoing social learning process in a complex ecological context (see, e.g. Bronfenbrenner, 1979).

Learning theories, although not identical, have a common feature that learning is viewed as a relatively stable change in the person's potential to behave; therefore, development means increase of potential to perform and to behave. Simple behavior like walking has to be learned once the maturational process makes walking possible. Similarly, social skills and thinking

systematically have to be learned when the child is ready to do so. The potential to perform higher order activities is not the result of spontaneous organismic growth, but is the outcome of learning appropriate techniques. Therefore, the child learns to demonstrate milieu-specific behavior patterns in coordination with the developmental process.

It is important to search for the mechanisms that govern the acquisition and modification of behavior, but it is unknown whether this approach "actually looks for mechanisms of acquisition and modification or whether it merely applies the preconceived notion that the growth of all behavior is caused by conditioning and thereby overlooks the actual mechanisms governing acquisition and modification" (Langer, 1969, p. 85). Evidently much of our behavior is learned and its acquisition, such as with language learning, often depends on our social environment. But these theories neglect the inborn abilities and the diversity of human characteristics. A single environment with specific learning opportunities is not the same for every developing individual exposed to it. One child may profit optimally while another is not at all affected.

### *Psychodynamic Theories*

Psychodynamic theories and learning theories both portray the environment as having a strong impact on human development. They differ in that the socio-affective component of personality and its development is considered to be fundamental in psychodynamic theories but is not central in theories of learning. The socio-affective component essentially determines the dynamics of the developmental processes.

Within the psychodynamic group, the most prominent theory is the psychoanalytic. According to this view the child is born with two fundamental forms of biological energy: libido and aggression. These two conflicting yet complementary classes of instincts are operative from birth. Libido or Eros is constructive, positive and life seeking; aggression or death instinct is destructive and life disturbing. The child is born with an id structure that is energized by libido and aggression. The id provides the child with the energy to satisfy his or her passions, but the environment inhibits this process. The id structure is transformed by its interactions with the environment into an ego structure. The superego emerges under the influence of the social environment, especially the parents, to control the behavior of the ego and the demands of the id.

Freud saw creative work as embedded in experience occurring early in one's life that is expressed in "a wish that finds fulfillment in the creative work" (1975, p. 133). John-Steiner (1987), in her provocative analysis of creative minds, emphasized the importance of visual imagery to the psychoanalytic approach to creativity. Visual images from wishes and fears in the unconscious are brought into conscious reality through a writer's (or artist's, poet's, scientist's) creativity with

language and other forms of expression. From this kind of explanation, a creative person would be expected to be closer to his or her unconscious than would other people.

Psychodynamic theory is primarily a theory of socioaffective development. A problem with this theory is empirical validation of the id, ego and superego, and the stages of sexual development (which are not covered in this chapter). Findings are obtained by the clinical therapeutic method; the data are therefore confounded with the therapist's interpretation. "Thus, not only are the data not reliable, but it is also not always certain which theoretical assertions they are relevant to" (Langer, 1969, p. 49).

Erikson (1963) broadened the Freudian perspective; he introduced a relationship between psychological, educational, and cultural factors. Erikson took a lifespan perspective and developed a framework of eight distinct stages. Developing individuals pass through those stages at specific periods in their lives. Each stage represents a conflict that must be resolved successfully for the person to be psychologically healthy. This approach stimulated research, especially in the infancy and adolescent periods. However, questions remain about whether psychodynamic theory really can be considered as scientific theory (i.e. is it falsifiable, testable, and can it be revised?). The traditions of this approach looking at developmental conflicts through analysis to reveal the mind's working continues to some extent.

### Interactionist Theory

The theories discussed so far are rather limited because each emphasizes a single dimension. A synthesis of the various aspects is necessary. The interactionist theory used by the great majority of Western psychologists and educators provides such a synthesis. The German psychologist William Stern (1871–1938) was the first to propose such a theory and called it the *theory of convergence*. In his view human development is a process in which personality and environmental factors converge (Stern, 1916). Yet, Stern never directly participated in the controversy concerning nature vs. nurture.

The former socialist countries favored the environmental theory. Human development was seen primarily as a mirror of the environment. According to Vygotsky, cognitive development is not a 'natural' process, but is determined by culture (see Van Parreren, 1983). Therefore, Vygotsky's position was that it is not necessary, as Piaget argued, to connect instruction in school with stages of development, but rather with the 'zone of proximal development', in other words, stimulate the child to do tasks that are just above his or her current ability level (Vygotsky, 1978).

Like Langer, some authors view Werner and Piaget as proponents of maturation. The human being is viewed as an active agent and development as merely a

self-constructive process. Development occurs from within. Werner characterized development as an orthogenetic process that is "directed towards increasing differentiation, centralization, and hierarchic integration of the child's mental organization" (Langer, 1969, p. 9). On the other hand, Piaget (1967) characterized development as an equilibration process (i.e. development proceeds from relative disequilibrium to increasing equilibrium). The child will always function to achieve equilibrium; in doing so, the child changes and develops. Langer characterizes Werner and Piaget as *organic lamp* theorists. It is true that these theorists emphasize maturation of the organism as a central agent of development. However, development only then takes place when the child *interacts* with his environment.

Therefore, Piaget (1896–1980) can be regarded mainly as an interaction theorist; however, he emphasized only cognitive functioning and the related issue of moral development. According to Piaget, development is a continuation of embryogenesis. Development occurs in a sequence of stages which, when reached, permit the child to perform at a higher level of cognitive operations. The development of a higher stage depends on *maturation, experience, and social transmission*; education and language play roles in social transmission. The most central factor, however, is the spontaneous activity of the child, because this activity brings the child through interaction between maturation and social environment to new forms of *adaptation*. This means the child is increasingly able to react adequately to the demands of the reality.

Piaget called the process of adaptation of the organism *assimilation*. If the organism has to adapt to new elements of the environment, the process is called *accommodation*. This last form of adaptation requires flexibility in mental operations. As a process of establishing equilibrium, accommodation brings the child to a higher cognitive level and the child establishes a higher structure for thinking. Structure refers to the scheme developed by the individual to achieve equilibrium between the tendencies of assimilation and accommodation. The result is a new process of accommodation that is necessary to establish a new or higher kind of operation that will disturb the existing equilibrium. The process of actively breaking through the existing equilibrium to establish a higher structure of thinking is called equilibration by Piaget. This active form of achieving a new equilibrium is a kind of *self-regulation*.

Interaction refers to mutual or reciprocal action or influence between a person and other people, objects, processes, or other elements of the environment. This includes the notion that the acting and reacting individual shapes the environment (e.g. with family, friends, classmates, social class). On the other hand, the individual influences the environment through experiences. In short, the individual is both a product

and a producer of the environment. The biological concept of *adaptation* introduced by Piaget has to be extended to emphasize the more active role of the individual. Sociologists use the term *emancipation*, to mean self-actualization, becoming an independent person, and detachment from inappropriate bondings.

It is evident that psychological development consists of more than cognitive development as emphasized by Piaget. Psychological development includes cognitive as well as social and personality aspects. Furthermore, it is a dynamic and life-long process; the interaction between the nature of the individual and the environment determines the motives that emerge and the kinds of behavior patterns that will become manifest. In short, psychological development is the result of interaction between the maturing individual and his or her environment. This view posits that development follows a universal pattern; a contrary view is that each individual develops differently (see Case, 1992).

As was emphasized earlier, conceptualizations of psychological development influence research directions and educational and psychological practice. All the theories briefly summarized here have influenced theory and concepts of giftedness and will continue to do so. Knowledge of developmental theories is necessary to understand what is 'behind' a definition.

#### *Other Perspectives*

It has been suggested that the traditional dependence on intelligence measures is misguided as a basis for identifying giftedness. One alternative is represented by the view that development in gifted children is an asynchronous process with unique cognitive and behavioral characteristics (Morelock, 1996). The assumption, is that the development of the child in the normative range of ability is synchronous.

Another type of asynchronous conceptualization of gifted development is provided by Feldman (2000). The approach here considers developmental activity to be on a continuum from universal (in all children) to non-universal (manifested relatively more in gifted children). The universal to non-universal dimension is based on the uniqueness of the domains of knowledge and experience across age, background, and culture. Therefore, Feldman claims that non-universal theory provides more appropriate framework for understanding gifted development and conducting research in the area.

#### **Definitions of Giftedness**

Defining giftedness is a task fraught with difficulty; a definition should give a formal and concise description of the meaning of a concept or a construct. Giftedness or the synonyms high ability and talent can assume different meanings. Frequently these meanings are tainted by an emotionalism that seems to engulf the concept of giftedness. For example, in German the

word for giftedness can be *Begabung* or *Hochbegabung*. The connotation of *Hochbegabung* can be value laden, associating giftedness with elitism. A similar situation exists in French (*doués* or *surdoués*). Such a connotation evokes emotional reactions and negative feelings that have hampered progress in programming for the gifted worldwide (Williams & Mitchell, 1989).

Further, a concise definition is almost impossible because the context in which the definition is made may refer to a process, key elements of giftedness, provisions for the gifted, or education of the gifted. In addition, it is not easy to separate theoretical and practical concepts because adherence to a theory of giftedness determines one's research and educational approaches. Finally, definitions seem more involved in practical concerns than in developmental theories.

Our definition is: *Giftedness is an individual potential for exceptional achievement in one or more domains.* On the other hand, according to Hany (1987) there are more than a hundred definitions of giftedness (and its synonyms). These definitions can be clustered in four distinctive groups. The first two of them refer to psychological constructs (i.e. genetically-based, and cognitively-based), a third focuses on achievement and accomplishment, and the fourth takes an environmental view. In the following section these four main groups of definitions of giftedness are presented.

#### *Innate or Genetic-Oriented Definitions*

The most prominent representative of the genetic-oriented approach is Lewis M. Terman (1877–1956) who popularized the concept of IQ and played a prominent role in the history of social science and management of scientific research. Terman believed that intelligence as revealed by intelligence tests is genetically determined and therefore stable over time. His belief in *biological determinism* was so strong that he only came to the conclusion in 1947 that "intellect and achievement are far from perfectly correlated" (Terman & Oden, 1947, p. 352). Evidence that he participated personally in that conclusion might be found in his own female students. In a carefully selected, highly talented group of thirty collaborators for his longitudinal research on gifted children, less than half of them were able to reach his standards for attaining the doctoral degree, and only a handful of those were able to reach prominence in the field (e.g. Florence Goodenough, Nancy Bailey) (see Rogers, 1999).

The new ideas that environmental and personality factors are significant determinants of "the extent to which a subject had made use of his superior ability" (Terman & Oden, 1947, p. 349) were most clearly spelled out in Terman's address at the University of California at Berkeley (Terman, 1954). Another central issue of Terman's work was the idea that he had a *mission* as a psychologist to contribute to the shaping of American society. He advocated a society that was a

*meritocracy*. More precisely, individual differences in ability to perform at high standards should be reflected in the hierarchical structure of the society: the most responsible positions should be held by the most capable individuals (that is, those with the highest IQ scores). A meritocratic social structure, however, based on the results of mental tests that identify innate characteristics at school age is an unrealistic ideal, not only because high intelligence is not isomorphic with high achievement, but human beings develop in a dynamic way and through interaction with the environment. Terman's view of intelligence as a unitary inherited ability reappeared in modified form in Marland's well-known definition of giftedness proposed in 1972.

Gifted and talented children are those identified by professionally qualified persons who by virtue of outstanding abilities are capable of high performance. These are children who require differentiated educational programs and services beyond those normally provided by a regular school program in order to realize their contribution to self and society. Children capable of high performance include those with demonstrated achievement and/or potential ability in any of the following areas:

- (1) General intellectual ability;
- (2) Specific academic aptitude;
- (3) Creative or productive thinking;
- (4) Leadership ability;
- (5) Visual and performing arts;
- (6) Psychomotor ability (Davis & Rimm, 1985, p. 10).

There were at least two new elements in this definition: (1) the definition goes beyond intelligence to other areas of high ability, and (2) abilities as well as achievement are criteria for identification. However, the definition excludes non-cognitive factors (e.g. motivation) as well as clear operationalization of the different forms of giftedness.

A committee convened by the U.S. government in 1993 generated the following definition:

"Children and youth with outstanding talent perform or show the potential for performing at remarkably high levels of accomplishment when compared with others of their age, experience, or environment. These children and youth exhibit high performance capability in intellectual, creative, and/or artistic areas, possess an unusual leadership capacity, or excel in specific academic fields. They require services or activities not ordinarily provided by the schools. Outstanding talents are present in children from all cultural groups across all economic strata, and in all areas of human endeavor". (Ross, 1993, p.3)

Unfortunately, this definition was not an improvement but "reflects the tensions and shifts that have been occurring in the field" (Feldman, 2000). It serves more as a description of gifted children than as a definition of giftedness.

When Gardner (1983) proposed his theory of multiple intelligences, he argued "that individuals have a number of domains of potential intellectual competence which they are in the position to develop, if they are normal and if the appropriate stimulating factors are available" (p. 284). Furthermore, there are conditions and criteria that have to be taken into account to identify a specific kind of intelligence. Criteria of an intelligence may be, for example, potential isolation by brain damage, support from experimental psychological tasks, or support from psychometric findings. Gardner identified several intelligences related to a specific domain of potential (linguistic, musical, logical-mathematical, spatial, bodily-kinesthetic, intra- and interpersonal intelligence; recently he added naturalistic and existentialistic intelligence).

The description of multiple intelligences or traits is primarily based on qualitative findings and idiographic analyses rather than empirical results (see Gardner, 1993). The important extension beyond Terman's approach is that giftedness results from inborn abilities in interaction with an appropriately supportive environment. The other point is that this definition goes beyond the opinion that giftedness is high intelligence as such, but rather expresses itself in different domains.

The genetic-oriented approach has led to an enriched empirical research. It has enabled extension of knowledge concerning characteristics and conditions for the development of giftedness and has led to better understanding of the processes of achievement of gifted people (e.g. Holahan & Sears, 1995).

### *Cognitive Models*

Cognitive definitions focus on thought process memory and related skills. For example, Piaget was less interested in the outcome of a test than the process of responding. Therefore, he emphasized clinical methods in which a single or small group of children were observed and interviewed while they were performing tasks rather than large-scale research in his approach. In his theory of knowledge, known as *genetic epistemology*, Piaget preferred to investigate how children attain knowledge and use it.

Proponents of the cognitive information processing approach have invested considerable effort in the direction suggested by Piaget's work. "The cognitive components approach is task analytic and attempts to directly identify the components of performance on tasks that have been generally used to assess mental abilities" (Pellegriano & Glaser, 1979 p. 188).

Sternberg is an important proponent of this approach (Sternberg, 1985; Sternberg & Davidson, 1986). A

central concept in Sternberg's experiential subtheory of intelligence is insight and response to novelty in task performance. Within this view a distinction is made between "three separate but related psychological processes" (Sternberg, 1985, p. 80): (1) *selective encoding*, i.e. sifting out relevant from irrelevant information; (2) *selective combination*, i.e. "combining what might originally seem to be isolated pieces of information into a unified whole that may or may not resemble its parts" (Sternberg, 1985, p. 80); (3) *selective comparison*, i.e. relating new information to that which was acquired in the past.

Insightful performance demonstrated as problem-solving skills or as knowledge-acquisition components are indicators of giftedness. The better these skills are, the more intellectually gifted a person appears to be. Moreover, according to the loci of information processing, Sternberg makes a distinction between three kinds of giftedness: analytic, synthetic, and practical abilities (Sternberg & Lubart, 1991). More recently he refers to analytic, creative and practical aspects of successful intelligence (Sternberg, 2000).

The constructive qualitative and empirical research approach of the cognitive models bodes well for the potential for progress in cognitive models. On the basis of current activity and interest in the field, it appears that as this approach matures, it will contribute to better understanding of the developmental processes underlying giftedness.

#### *Achievement-oriented Models*

Even Terman, the most rigidly genetic-oriented author, was convinced by his own empirical data that high intelligence was only a necessary but not a sufficient condition for highly able behavior. As a result he considered *achievement* as the observable output of giftedness. As early as 1916, the noted German psychologist William Stern considered high intelligence as a necessary but not sufficient condition for outstanding achievement. He considered personality traits like motivation and environmentally appropriate conditions important (Stern, 1916). However, his arguments were more supported by careful observation than by controlled empirical research.

The most influential author in the achievement orientation category is Renzulli. His article "What makes giftedness?" (Renzulli, 1978) has had a long lasting impact on the field. A thorough literature review revealed that there are at least three traits or factors involved in gifted achievement: (1) above average ability, (2) task commitment, and (3) creativity. These three clusters of variables are brought together in Renzulli's "three-ring conception" that characterizes highly productive people.

The history of the groundbreaking 1978 article by Renzulli is more than interesting. Renzulli wrote in 1998: "November, 1998 was the twentieth anniversary of the publication of my article on the Three Ring

Conception of Giftedness in *Phi Delta Kappan* magazine. This article, which was rejected for publication by the major gifted education journals at that time, is now the most widely cited publication in the field; and its influence is being manifested in the more flexible ways that schools go about identifying students for special services" (Renzulli, 1998-99, 1).

The research base of the three-ring conception has been attacked by Jarell & Borland (1990) who argued that the research they reviewed does not support this conception and moreover, the research is either irrelevant or contradictory to the triad.

The article by Jarell and Borland provided Renzulli (1990) with an opportunity to react in a constructive and convincing way. Most important, Jarell and Borland did not examine the most recent theory and research on the three-ring conception. Furthermore, the intention of Renzulli's conception is threefold: "(a) to call attention to the developmental nature of behaviors such as creativity and task commitment, (b) to highlight the dynamic interaction among behaviors that is necessary in order for gifted behaviors to emerge, and (c) to provide enough flexibility in selection procedures . . ." (Renzulli, 1990, p. 325). Giftedness has to be seen as a manifestation "of human potential that can be developed in certain people, at certain times, and under certain circumstances" (p. 324). Renzulli's overall intention in his approach is to be able to identify and to nurture giftedness appropriately. The multicomponent conceptualization of giftedness can be regarded as one of the better definitions.

However, a definition that strongly or exclusively emphasizes personality traits neglecting the interactive nature of human development does little justice to the dynamic interplay of the developmental processes. A multidimensional approach, including personality and social components as determining factors, seems to be an appropriate framework. The following modification was made by Mönks working from a developmental psychology perspective in his Triadic Interdependence Model of Giftedness (see Mönks, 1992a, p. 191), now called Multifactor Model (Mönks, 1998). This model consists of personality and environmental aspects. Task commitment was replaced by *motivation* which includes task commitment, risk taking, future time perspective, anticipation, planning and emotional factors. Emotional factors as aspects of ability are considered in the model (Golman, 1995).

Furthermore, the rather liberal above-average ability criterion was replaced by *outstanding abilities* in specific domains exceeding 5-10% of performance. Environmental factors include the main social contexts in which the child and adolescent mature: family, school and peer group. Emergence and development of gifted potential depend to a great extent on a supportive environment. Intellectual peers or developmental equals are significant people who are needed for

healthy social and psychological development. All children need peers to interact with and from whom to learn, and this is true with the gifted.

Authors working with an achievement orientation make a distinction between potential and realized capacities. In serving the needs of underachievers it is important to know the potential of a person and how much of that potential has been realized. Knowledge of the discrepancy between potential and realized abilities provides opportunity for intervention. The advantage of achievement oriented models lies not only in the interconnection of identification and education, but also that attention is paid to the processes involved in achievement and the recognition that there are non-cognitive and environmental factors that influence the realization of innate human potential.

### *Systemic Models*

As was indicated earlier, the social systems (family, school, and peers) have an impact on human development. However, it is evident that other systems also have an impact on the development of each individual. The *Zeitgeist* (or world view represented in the society at the time), the economic situation, the political orientation, and the culturally dominant values and beliefs all have influence on human development and therefore on the development of gifted youth. To a certain extent, it might be said that the systemic approach is the opposite of 'ontogenic stability'.

According to Tannenbaum (1983), who takes a systemic approach, outstanding achievements are determined equally by the following five factors: (1) general ability, (2) special ability, (3) non-intellective factors, (4) environmental factors, and (5) chance factors. Tannenbaum arranged these factors in the shape of a star, and thus his definition is called the star definition (see Tannenbaum, 1983, p. 87; Feldman, 1992). Society determines who is regarded as gifted. From the societal perspective, a distinction can be made between 'scarce talents', 'surplus talents', 'quota talents', and 'anomalous talents'. A society always has criteria for the attribution of what is talented and gifted in terms of outstanding achievement (see the first Tannenbaum chapter in this volume).

The systemic perspective includes interacting influences that affect a child's life and development. Beyond the family, they might include the schools, political system, economic environment, social agencies, cultural practices, and related factors. Development of giftedness may come from opportunities provided by different agendas within various units of the system.

Definitions of, and perspectives on, giftedness give direction to research and practice. The interconnection and interdependence of the individual and society affect both the gifted and the non-gifted. The detrimental effects of not serving the special needs of gifted individuals will affect society at large. Programs for the

gifted are not special in the sense that they advocate giving to each individual what is appropriate for him or her.

### **Research on the Development of Gifted Children**

A casual review of the literature suggests that definitions of giftedness are more influential on the research of gifted development than the theories of development. This may be the result of a practical and educationally oriented grounding of the definitions. For this reason, research presented here is organized more along definitional than theoretical lines.

### *Innate or Genetic-oriented Research*

Although early interest in intelligence could be attributed to the work of Sir Francis Galton, Karl Pearson, Alfred Binet, and others, the beginning of formal scientific research in giftedness has frequently been credited to Terman for his development of a technically sound method of assessment of intelligence and his longitudinal studies of gifted individuals. In these studies, Terman postulated that individuals developed within the limits of their genetically preordained intellectual abilities (Grinder, 1990; Cravens, 1992). Terman's long developmental investigation started in the 1920s initially involved more than 1500 children and adolescents from 5 to 16 years of age, and is still ongoing. The group was selected based on an IQ score of 135 or higher as determined by the Stanford-Binet Test. This research has continued with latest results published in 1995 (Holahan & Sears, 1995).

Because of the influence of Terman's contributions, much of the research on giftedness has taken a genetic orientation emphasizing intelligence testing and other psychometric approaches to the identification of intelligence as a general static trait that determines gifted capacity (e.g. Macmann, Plasket, Barnet & Siler, 1991). However, other analyses have challenged the assumption that high IQ scores and general intelligence are (1) genetically determined, and (2) necessarily required for, or reflective of, gifted performance (O'Connor & Hermelin, 1988; Silver & Clampit, 1990).

The genetic-oriented view prevails in research looking for the multiple traits of the gifted child; in studies of the performance of gifted children, an IQ test is frequently used to identify the gifted sample. Such studies have investigated a wide range of traits of gifted populations in addition to performance and achievement. For example, the Shigaki and Wolf (1980) investigation of children's syllogistic reasoning; Carter's (1985) studies of Piagetian task performance; research by Derevensky and Coleman (1989) and Henderson, Gold and Clark (1984) on gifted children's fears and daydreaming, and various studies of personality and socialization (e.g. Altman, 1983; Olszewsky, Kulicke & Krasney, 1988; Luftig & Nichols, 1991; Keller, 1992).

In recent years, research that questions the validity of using IQ test scores for identifying present and future gifted performance in specific academic and skill areas has been increasing. Along with this drift away from the general trait conception of giftedness represented by the IQ score, interest has been directed to identification of giftedness in groups that had previously not been considered gifted such as handicapped, underprivileged, and ethnically divergent minority groups (Baldwin, 1987; Sekowski, 1992; Armour-Thomas & Gopaul McNicol, 1998). This new interest in giftedness among non-traditional populations is leading to a broadening of criteria for identification. For example, Schack and Starko (1990) reported that teachers emphasized creativity, learning speed and ease, curiosity, and initiative in seeking one's own learning experiences as essential for academic giftedness, but more experienced teachers also emphasized the IQ score. A trait model that emphasizes multiple intelligences like Gardner's is becoming more compatible with research evidence than the single trait models relying on IQ scores for identification of giftedness.

Another promising approach is that of human behavioral genetics. It is, for example, now possible to identify with greater precision of how the environment has an impact on cognitive abilities (see, e.g. Thompson & Plomin in this volume).

### *Cognitive Models*

Much recent literature that comes under the influence of cognitive definitions seems to represent the trait of giftedness functionally rather than by intelligence test score. For example, numerous investigations of giftedness in mathematics emphasize mathematics performance as the criterion (e.g. Benbow & Arjmand, 1990; Benbow & Minor, 1990). Facaoaru and Bittner (1987) have advocated diagnostic procedures for identifying the gifted using techniques and concepts from cognitive research such as procedural thought processing, spatial abilities, and problem solving. Further, the analysis of thought processes determined by verbal comments recorded during problem solving has proven useful in identifying how gifted students learn (Shore et al., 1992). In a more extreme position, Mason (1992) advocated the identification of giftedness on the basis of analysis of task performance and cognitive skills. This approach has been successfully implemented by Claypool (1994) in a study of how young children learn to read. Children were identified as learning in accelerated or delayed rates using this method. The focus on functionality and mental processing is a reflection of the increased interest in the cognitive orientation in recent years.

Advances seem to be rapidly occurring as a result of cognitive science, spurred by the merging of numerous disciplines (e.g. psychology, computer science, engineering, mathematics, physiology, neuroscience) into a

specialty that focuses on intelligence and ability to perform (Luger, 1994). From this position, Minsky (1986) argued that giftedness was in the management of learning and cognitions. Naglieri and Das (1997) have taken an approach to cognitive assessment that is very different from the more traditional IQ measures. It is founded in the neuropsychological theory of Luria (1980) and emphasizes the cognitive processes planning, attention, and simultaneous and successive processing (Naglieri, 1987; Naglieri, Das, Stevens & Ledbetter, 1991; Das, Carlson, Davidson & Lange, 1997). The impact of these newer approaches to cognitive ability on the identification of the gifted is still to be shown.

A factor leading to the increase of cognitive research in giftedness is the growth of the information sciences and computer technology. These advances in technology have been particularly influential on research in cognitive psychology (Thorndike, 1984; Beer, 1990). The new technology has greatly increased the ability to present complex stimulus and problem solving situations. It also renders the study of constructs like response time more plausible and accurate than was previously possible. In addition, computers have led to models of human information processing (e.g. Ellis & Hunt, 1989). Cognitive psychology has focused on the study of such subjects as the nature of expert thinking, the formation of a construct, and elements and structures of productive mental processing. This approach is reflected in studies showing that mathematically gifted students were able to express verbal statements of quantity and relationship mathematically more readily than their peers or college students taking mathematics courses (Dark & Benbow, 1990), and that verbally gifted students excel in different cognitive tasks than mathematically gifted students (Benbow & Minor, 1990). Further, by focusing on mental processing, Borland (1989) found divergent thinking was associated with a 'strict percept-strict concept' cognitive style. In addition, Carter (1986) reported that teaching students higher level thinking skills led to greater success among gifted students in learning the concepts and reasoning but not in leading the gifted students to reach higher developmental levels of thought. In addition, research emerging from a cognitive orientation is beginning to shed light on the complex relationship between the brain, high level performance and ability, and biological, psychological, and social status (Clark, 1986; Petersen, Crockett & Graber, 1990; Luger, 1994; Bownds, 1999).

### *Achievement-oriented Models*

Achievement-oriented research on the gifted suggests rather consistently that children who are identified as gifted at a young age tend to continue to be identified as having high ability and accomplishment later in life (Milner & Elrod, 1986; Mönks, 1992b; Benbow, 1992). For example, accelerated readers seem to maintain an

edge over other students, but the difference is less as they get older. Further, in Western cultures boys are more likely to sustain gifted performance and interest in science and mathematics than girls. In addition, experience with the contents of the educational curriculum prior to studying it (e.g. through involvement with preschool or after school programs or hobbies), family characteristics such as parents educational attainment level, and attitudes toward education, students' interests and attitudes towards learning, and access to experiences all seem to contribute to one's being identified as gifted (e.g. Hannah & Shore, 1995; Jones & Day, 1996).

The importance of special programming for the academic development of the gifted has been shown. For example, Brown and Rogan (1983) have addressed the effects of maintaining gifted children in rigid reading programs designed for a particular grade level. According to these authors, these children can become frustrated about independent reading because they already have skills above what they are being taught. This can lead to disillusionment and poor study habits and the paradox of poor levels of achievement by gifted students (Boyd, 1990).

Evaluation studies by Heller and his group (1998) demonstrate especially that the impact of peer interaction is of great and lasting value. From a developmental viewpoint it is extremely important that gifted individuals can interact with developmentally equals.

### *Systemic Models*

Systemic models emphasize the effects of social systems on the development of the gifted. Research in this area has focused on the family and home environment of gifted children (e.g. Colangelo & Dettmann, 1983; Cornell & Grossberg, 1987; Prom, Johnson & Wallace, 1987; Green, Fine & Tolleson, 1988; Cornell, Callahan & Lloyd, 1991). This research suggests that the family and home environment play an important role in the development of the gifted. For example, the research suggests that the home environment affects emotional adjustment, achievement satisfaction, and academic success with a tendency for the most cohesive, child-centered, and functional family environments to produce the most successful students. On the other hand, giftedness in creative expression seemed to be greater from the less child-centered and tense family situations. Similar findings for scholastic performance with low income minority families have been reported (Prom, Jackson, Johnson & Wallace, 1987). Other researchers (e.g. Klein & Cantor, 1976) have found lower self-esteem levels in gifted children in kindergarten to fourth grade. It has been suggested from this finding that the gifted child was more sensitive to the environment and had greater need for approval from family and friends than his or her less able peers. This social sensitivity was sup-

ported by a study of gifted and learning disabled children which reported the gifted were more able to identify and label prosocial behavior (Abelman, 1991).

Peer relations and cultural influences also seem to play a significant role in gifted development. For example, subtle cultural values may have been influential in producing the findings of Luftig and Nichols (1991) that gifted boys tended to be the most popular students while gifted girls least popular in a group of fourth through eighth graders. Young gifted students have also been found to show a tendency toward choosing older (Janos, Marwood & Robinson, 1985) and more popular (Schneider & Daniels, 1992) students and leaders to be their playmates and friends. In general, the social psychological literature seems to provide substantial support for the kind of model proposed by Mönks (1992a) which integrates Renzulli's three-part model with the family, peer, and school environments.

As was pointed out earlier in this chapter, cultural environment can determine whether or not a child is exposed to opportunities for the giftedness (Lowenstein, 1979; Merenheimo, 1991). Female students are often not selected to participate in gifted programs in societies in which male dominance is well established in the educational system (Ayles, 1992). In addition, research findings have suggested that children who come from different cultural backgrounds than the majority of their peers may experience reduced opportunity to become identified as gifted despite evidence that such children give a fairly good account of themselves when they are chosen to participate in gifted programs (Baldwin, 1987; Robinson, Bradley & Stanley, 1990; Cooley, Cornell & Lee, 1991; Smith, LeRose & Clasen, 1991).

### **General Trends in the Research Literature**

The general trends in the research literature seem to be changing. Previously research in the field of development of giftedness tended toward descriptive and case study methodology rather than more complex designs and sophisticated statistical analysis (Carter & Swanson, 1990). As noted by Gallagher (1986), practical needs and realistic solutions seemed more influential in the contents of the research literature than high level theories of the sort proposed by Erikson (1963), Piaget (1967), or Bandura (1986). Theory-oriented research tends not to have immediate or widespread influence on practice.

More recent research seems to be directed toward the development of theories and models that would explain and provide methods for identifying and working with the gifted. For example, theories and approaches from cognitive psychology like Sternberg's (1985; Sternberg & Horvath, 1998) have been applied to performance studies of gifted (Zhang & Sternberg, 1998; Dai & Feldhusen, 1999). In addition, prior

knowledge, metacognition (what is known about what one knows), cognitive flexibility, speed, and problem solving seem to be more prevalent in the recent literature (Mills, Ablard & Gustin, 1994; Hannah & Shore, 1995; Jones & Day, 1996; Dresl, Ziegler, Broome & Heller, 1998). In addition, advances in biology and genetics have begun to yield studies on specific genes that may be involved in the development of gifted performers (e.g. Skuder et al., 1995). However, this particular kind of effort still seems a long way from providing useful applications.

Finally, the newer research seems more focused on gifted performance in specific areas such as science, mathematics, and literature rather than general realms like total academic performance. In view of the themes in the recent literature, the reminder of Horowitz & O'Brien (1986), about the importance of the developmental perspective is useful. Better understanding of the processes of development to include learning, cognitive mechanisms, emotion and temperament, and social and environmental factors through the life span will lead to more effective identification and provision for the gifted.

#### *Teaching and Instruction Based on Developmental Psychology*

A considerable portion of the research literature deals with how to teach gifted students (e.g. Milgram, 1980; Wang & Walberg, 1983; Horowitz & O'Brien, 1986; Slavin, 1987; Reis & Renzulli, 1989; Whitlock & DuCette, 1989; Swiatek & Benbow, 1991; Vaughn, Feldhusen & Asher, 1991). As this literature would suggest, many forms of instructional practice exist to serve the special needs of gifted children. These approaches can include some form of ability grouping (between- or within-class), cooperative learning, or pull-out programs. A further distinction can be made between homogeneous and heterogeneous grouping. However, the content of the program rather than instructional practice is most important; certain instructional practices enable gifted children to learn at their own pace and level of ability. On the other hand, the content of the program enriches and motivates students who are highly able. Close examination of the research indicates that the various programs do tend to have positive influence on achievement, creativity or critical thinking (see Buchanan & Feldhusen, 1991). However, there is no clear indication of what is the most effective means of serving the academic needs of gifted students. To be able to identify the best practice requires comparison of all practices; this kind of research is both rare and difficult to do. Another conclusion that might be drawn from the literature is that academic arrangements designed to provide differentiated learning experiences for students of different ability levels are more effective than traditional

undifferentiated approaches. It is also clear that the educational effectiveness of a particular instructional practice depends on the characteristics of both teacher and student, and on social and developmental factors. Certain methods are most beneficial in certain environments for particular students. Further, what is beneficial in grade 3 need not continue to be beneficial in later grades.

The most beneficial educational approach, however, is the approach that fits the developmental needs of the individual child. Vygotsky did not regard cognitive development as a process of nature (see Van Piareren, 1983), thus suggesting that education and instruction need not be fitted to a particular developmental level or stage, as Piaget argued. Vygotsky's position (1978) is that instruction creates development (to a certain extent), because learning and development take place within the zone of proximal development. Tasks within the zone of proximal development are too difficult for the child to do alone; these tasks become possible with guidance and assistance from adults or older children. As new technology comes into the classroom with its potential of making many aspects of education more experiential and meaningful to children, the challenge will be to use developmental theories to apply these powerful tools in effective ways to meet the needs of the gifted learner (Grabe & Grabe, 1998).

#### *Montessori's and Petersen's Contribution to Gifted Education*

Another developmental position has been defended and elaborated upon by Maria Montessori, a person who played a leading role in the school reform movement started in Europe in the early 1920s. This movement influenced schools to become institutions where children were accepted and treated as individuals. Child-centered education was felt to be most beneficial for the healthy development of children.

Maria Montessori (1870–1952) grew up as an only child in a family with a father who believed in traditional values and role patterns. She aspired to a technical career but a daughter in a 'male profession' was beyond her father's conservative value system, and he could not accept his daughter's choice of study. Maria Montessori was a mathematical prodigy, and at the age of 26 became the first woman physician in Italy's history. Although not a trained pediatrician, she became famous as an expert in children's illnesses.

A central component of the Montessori theory is the concept of *sensitive periods*, or genetically determined developmental periods during which the child is especially eager and able to master specific tasks, similar to critical periods. During these periods the child works with a high level of interest to improve these abilities. However, "if the child is prevented from enjoying these experiences at the very time when nature has planned for him to do so, the special

sensitivity which draws him to them will vanish, with a disturbing effect on development . . ." (Montessori as cited in Crain, 1980, p. 56).

Other central concepts of Montessori education are *prepared learning environment* and *freedom of choice*. The proper environment will contain materials and means that correspond to the developmental needs of children; the role of parent and teacher can be described as 'facilitator'. To be successful in this role, parents must be aware of the specific developmental needs of the child, not only during early childhood but throughout the child's developmental period. Therefore, *ongoing careful observation* is necessary to give to the child needed experiences. Observation of the child enables the parent and teacher to make the right choices of supportive materials for the individual's development; freedom of choice is the opposite of teacher dictated learning.

The Montessori elementary school with its mixed age groups (normally more than one age group is found in a class) provides possibilities for independent as well as cooperative learning. Ability grouping is a normal instructional practice in the Montessori school. According to Maria Montessori, assigning children to grades on the basis of age is not a good practice (Holtstiege, 1991). A school must provide the possibility for an individual to progress at his or her own pace and level of learning; this principle is at the core of all gifted education.

The Montessori school encourages children to become independent learners and productive thinkers, and to love learning; a curriculum based on Montessori education principles provides for *qualitative differentiation*. That is, children are allowed to proceed at their own pace according to their own interests and needs. A differentiated curriculum is a prerequisite for appropriate and effective gifted education. Analysis of the Montessori system with regard to the elements beneficial for gifted education would be useful and helpful to the field. Crain (1980) accurately stated that, "Montessori demonstrated, as much or more than anyone else, how the developmental philosophies of Rousseau, Gesell, Piaget, and others can be put into effective practice. She showed how it is possible to follow children's spontaneous tendencies and to provide materials that will permit them to learn on their own" (p. 72).

Peter Petersen (1884–1952) was one of the prominent and influential leaders of the *School Reform Movement* or *Progressive Movement* (e.g. Dewey or Washburn). In 1923 he founded, as professor of education at the university of Jena (Germany), a laboratory school of which he was director until 1950, when the school was closed by the then socialist Government. This experimental school became the place for the realization of new educational concepts and an important institution for teacher training. Actually, it was a *School for the Gifted Learner*,

because all the necessary elements were included in his system. For example, he regarded the age graded class as 'unnatural' and realized an age heterogeneous grouping with three different age levels similar to that in a normal family. Actually, the roots for gifted education go back to the *School Reform Movement* and the Jena plan principles demonstrate that gifted education is possible in the regular school. The following principles are core concepts of the Jena plan:

- ability grouping;
- independent as well as group learning;
- cooperative learning;
- progress according to individual ability and pace;
- social learning.

At the beginning of the new millenium we can conclude that the *School Reform Movement*, which has its roots in the beginning of the 20th century, established the road to the *Gifted Education Movement in Europe* a century later.

#### Concluding Remarks

Theories of development contribute to our understanding of the gifted. These theories provide different perspectives on the innate, systemic, psychological, and experiential background and tendencies affecting gifted performance. Developmentally oriented definitions of giftedness have broadened from the foundations laid by Terman and other early workers. Cognitive research and systemic views are becoming more influential. Research in the development of the gifted seems influenced by practical concerns but theoretical interests are becoming more evident. These efforts coupled with improvements in educational and instructional practice, the availability of technology, and public awareness of the developmental and learning needs of the gifted portend improved methods for development of the gifted (see Mönks, 1998).

# Genetic Tools for Exploring Individual Differences in Intelligence

Lee Anne Thompson<sup>1</sup> and Robert Plomin<sup>2</sup>

## Genetic Tools for Exploring Individual Differences in Intelligence

When the first edition of this handbook was published in 1993, general intelligence was the most widely studied behavior in the field of human behavioral genetics. A multitude of studies using a variety of research designs had clearly demonstrated that genetic influences on individual variation in intelligence are substantial. A survey of scientists found that most agree on this point (Snyderman & Rothman, 1987). The solidity of the finding led researchers in the field to conclude that no further quantitative genetic studies were required simply to demonstrate that genetic factors contribute to intelligence (Plomin et al., 1994, p. 107).

This statement should not be viewed as an endpoint but rather as a launching pad for the exciting cutting-edge research that has since ensued. Genetic research is now free to tackle more interesting issues surrounding the etiology of intelligence. For example, current molecular genetic research is uncovering specific genes that contribute to individual differences in cognitive function which will ultimately lead to a better understanding of the biochemical structure and regulation of cognitive processes. Advances in brain imaging have led to genetic studies of brain function during cognitive processing. New quantitative genetic techniques are merging with molecular genetic techniques to provide additional leverage on the genetic foundations of extreme groups, in this case, individuals with mental retardation and individuals who are intellectually gifted. Multivariate genetic analyses have revealed that the genetic variance influencing specific cognitive abilities is shared across abilities. In other words, genes are operating in a molar rather than a modular fashion. Perhaps most importantly, we can now tackle with

greater precision issues of how the environment impacts on cognitive ability when genetic influences have been taken into account.

We hope to provide an overview of how this fascinating area is currently unfolding. Before we begin our update of current research, it is important to present a brief description of the methods used to study genetic influences on cognitive ability and also to highlight some common misconceptions.

### *Quantitative Genetics*

The foundation for studying genetic influences on individual differences in intelligence and cognitive abilities is quantitative genetic methodology; primary to all quantitative genetic methods is the concept of variability or individual differences. Always bear in mind that quantitative geneticists do not try and explain the development of any one individual nor do they try and tackle species-wide developmental issues. Partitioning variance into either genetic or environmental categories simply explains how much of the observed differences across individuals can be explained by genetic or environmental factors. When you observe a classroom of first graders, you cannot help but wonder why some of the children are reading simple sentences effortlessly while others are still struggling with the identification of single letters and their sounds. To understand how genetic and environmental influences work together to create this striking pattern of variation in early reading skills, genetic and environmental influences must be separated.

The majority of research on the genetics of intelligence has involved the normal range of variation. Behavioral geneticists use a statistic called 'heritability' to describe the proportion of phenotypic variance that can be accounted for by genetics; to estimate the heritability of human behavior, samples of genetically informative individuals are studied. For example, adoptive parents and their adopted children share environments but not genes, while adopted children and their birth parents share genes but not environments. If adoptive parents resemble their

adopted children, then environmental influences are operating; if adopted children resemble their birth parents, then genetic influences are operating. The comparison of identical and fraternal twins can also estimate heritability through the simple subtraction of correlations. Since identical twins are 100% genetically identical and fraternal twins are on average 50% genetically the same, subtracting the identical and fraternal twin correlation and doubling that difference, yields a rough univariate estimate of heritability or  $h^2$ . Currently, more sophisticated methods of estimating  $h^2$  are typically used (McArdle & Prescott, 1997) and involve regression and/or structural equation models. These approaches are advantageous because they provide tests of significance through the simultaneous estimation of standard errors for the parameter estimates, allow for multivariate analyses, and in the case of regression analyses, are not as affected by non-normality in the distribution of the behavioral trait under study.

Traditionally, behavioral geneticists have broken environmental influences into two main categories, shared and non-shared. Shared family environmental influences ( $c^2$ ) are those experiences that family members are all exposed to and that create similarities among family members. For example, they share the same home and neighborhood; the siblings may all attend the same school system and in some cases have the same teachers; parents may to some degree treat their children in a similar manner. In contrast, family members are also exposed to unique experiences; the oldest child may have more responsibilities than the youngest; one child may have a peer group that is dramatically different from another child; parents may also create unique experiences for each child. Experiences that create dissimilarity among family members are called non-shared environmental factors or  $e^2$ . Distinguishing the two types of environment is important because developmental psychologists have emphasized the importance of shared family environmental factors, while behavioral geneticists have consistently pointed out the relevance of non-shared factors (Scurr, 1996). Furthermore, many identified shared family environmental influences have been shown to be mediated by genetic factors (Plomin & Bergeman, 1991; Plomin & Petrill, 1997).

Although most behavioral genetic studies of intelligence tend to conceptualize environmental influences as experiential factors that are manifested in a psychological, social and/or cultural manner, it may be more accurate to portray environmental parameter estimates as 'non-genetic' instead of environmental (Jensen, 1997). Non-genetic biological factors would also be categorized as shared or non-shared environment. Jensen has further proposed that much of what is categorized as non-shared, excluding error variance, can be thought of as 'micro-environmental' influences. He hypothesizes that these are random small environ-

mental effects that accumulate to impact on individual variation.

To briefly summarize the vast literature on general intelligence across the normal range of ability, heritability accounts for roughly 50% of the phenotypic variation, shared environmental influences account for 10–20%, thus leaving 30–40% of the variation to non-shared environment and error (Chipeur, Rovine & Plomin, 1990; Plomin & Petrill, 1997). However, it is important to remember that these estimates are applicable only to the populations from which the samples were drawn and may vary across age; heritability represents what was happening in a given sample, at a specific time, on a particular trait as reflected by a specific measure. Change any of these conditions, and the parameter estimates may change as well. Although a great deal of research converges on these estimates of  $h^2$ ,  $c^2$ , and  $e^2$ , the majority of the studies contributing to these estimates included a normally distributed group of relatively homogeneous individuals.

#### *Recent Advances in Quantitative Genetic Research*

As previously mentioned, estimates of heritability and environmentality are necessarily fluid; recent studies have begun to explore what factors can change the magnitude of these estimates. Some of the questions addressed include changes in heritability and environmentality across age, across levels of intelligence, and across environments.

*Changes in heritability and environmentality across age.* Developmental behavioral genetic studies have consistently suggested that as children mature from infancy through adolescence the magnitude of  $h^2$  increases and  $c^2$  decreases. Loehlin (1997) provides a nice overview of this literature. Twin studies show an overall pattern of high similarity for both Mz and Dz twin pairs early in life and a tendency for Mz twins to remain highly similar while the similarity of Dz twins gradually decreases across age. The increasing difference between Mz and Dz degree of similarity leads to higher heritability estimates with age; as the Dz pairs become less and less alike, the influence of shared family environment also drops. Adoption studies show a similar pattern in that adoptees have a moderate level of similarity with their siblings and parents with whom they share no genes during childhood; but once adolescence begins and especially after high school, the similarity drops to almost zero. In contrast, the resemblance between the biological parents and their adopted-away children increases throughout childhood and reaches a level similar to parents and children in non-adoptive families by adolescence (Plomin, Fulker, Chorley & DeFries, 1997).

An important Swedish study of twins reared apart and tested as elderly adults, called SATSA (Pederson, Plomin, Nesselbroade & McClearn, 1992), indicates that the trend for increasing heritability continues

throughout the lifespan and model-fitting results from this data set, yielding a heritability estimate of 0.80. Intelligence data collected in another study of twins reared apart based in Minnesota and tested during adulthood yielded similar results (Bouchard, Lykken, McGue, Segal & Tellegen, 1990). This trend towards higher heritability may not apply to very late in the life span. A study of Swedish twins over 80 years of age found a more modest heritability of 0.62, although this lower heritability might be due to lower reliability of psychometric tests with very old individuals (McClearn et al., 1997).

*Changes in heritability and environmentality across levels of intelligence.* Studies involving samples of selected individuals or individuals who score extremely high or low may provide different estimates of  $h^2$ ,  $c^2$ , and  $e^2$ . Several recent studies have attempted to test for differential effects of genes and environments across the IQ range; two distinct regression approaches have been used that address different issues. The first approach involves an exploration of changes in individual difference  $h^2$  or  $c^2$  across the IQ continuum; for example,  $h^2$  and  $c^2$  are typically thought to be consistent across the normal range of IQ. These parameters can be estimated and tested for their significance by predicting one twin's IQ from their co-twin's IQ, a coefficient of relationship,  $R$  ( $R=0.5$  for Dz twins and  $R=1$  for Mz twins) and their product. The same approach can also test for a significant change in the amount of variation accounted for by  $h^2$  and  $c^2$  across the IQ continuum by adding an interaction term consisting of the product of the co-twin's IQ, the coefficient of relationship, and a diagnostic index in this example, the IQ score. This regression approach was developed in a series of papers by John C. DeFries and David W. Fulker (DeFries & Fulker, 1985, 1988; LaBuda, DeFries & Fulker, 1986) and is called DF analysis. This approach addresses a very interesting conceptual issue with practical implications. If heritability is significantly higher for one part of the continuum, then researchers could look for environmental factors that may account for the differences. Studies applying this methodology have been inconsistent to date; for example, two different papers have found evidence for higher heritability at the high end of the IQ continuum and higher common environmental influences at the low end (Bailey & Revelle, 1991; Thompson, Detterman & Plomin, 1993), while two other papers have found no differences in either  $h^2$  or  $c^2$  across the continuum (Cherny, Cardon, Fulker & DeFries, 1992; Sundet et al., 1994). These inconsistencies may be due to several factors but three are most likely to be critical. First, sample sizes, while reasonably large for standard estimation of  $h^2$  and  $c^2$ , are inadequate to provide the necessary power to detect moderate-to-small changes in parameter estimates; much larger samples are

needed. Second, the majority of behavioral genetic studies have used samples that under-represent the low end of the IQ continuum. Subjects with IQs from the lower quartile are harder to recruit, harder to test, and harder to retain in studies. Finally, given that heritability increases and shared environment decreases across age, the age range of the subjects in the studies may have an impact on the findings. The studies included subjects ranging in age from infancy through old age; those that found significant differences included subjects who were predominantly between the ages of 5 and 18.

The second use of DF analysis is to estimate another type of heritability, group heritability or  $h_g^2$ . This parameter is not about individual variation but instead explains the etiology of mean differences for selected extreme groups. If a group of gifted individuals with a mean IQ of 150 is compared to a group of average IQ individuals with a mean IQ of 100, an obvious question is "What factors create this 50-point mean group difference?" A significant estimate of  $h_g^2$  would suggest that this difference is due in part to genetic differences across the groups. This is in contrast to the previous analysis which explains individual variation not mean differences between groups. Similarly, estimates of group shared environment,  $c_g^2$ , can also be obtained.

Group heritability was estimated for high and low IQ groups from the SATSA study conducted in Sweden and involving elderly twins (Saudino, Plomin, Pederson & McClearn, 1994),  $h_g^2$  was high, hovering around 0.75, in both the high and low groups. In a sample of twins ages 5–13 years, Thompson, Tiu, Spinks & Detterman (1999) found similar results for a high IQ group (selected to be at least 1.25 standard deviation above the sample mean,  $h_g^2=0.67\pm0.24$ ), but contrasting results for the low IQ groups (selected to be at least 1.25 standard deviations below the mean. For the low IQ group, group heritability was low and non-significant ( $h_g^2=0.27\pm0.27$ ) while group common environment was appreciable ( $c_g^2=0.63\pm0.23$ ). Once again, the discrepancies across the studies are most likely due to age and/or sampling differences across the studies.

*Changes in heritability and environmentality across environments.* Assuming that the evidence for the greater influence of common family environment at the lower levels of general cognitive ability can be shown to be a reliable effect, research should then address the issue of what causes the effect. Preliminary work from the Western Reserve Twin Project (Thompson et al., 1999) provides a small piece of evidence. The DF analyses that was previously conducted looking at differential heritability across the continuum for general cognitive ability was a univariate analysis in that the heritability of IQ was estimated across the continuum of IQ. These analyses can also be conducted in

a bivariate manner where the heritability of IQ is estimated across the continuum of another variable, in this case fathers' occupation. The WRTP did not include direct assessments of the twins' environments; however, fathers' occupational status may be an indirect reflection of both the father's intellectual level and a global variable reflecting common environmental factors. Fathers' occupational status was measured on a 7 point scale, with low values representing more prestigious/higher paying occupations and high values representing relatively unskilled occupations. When the average twin pair differences for general cognitive ability for MZ and DZ twins was plotted against each of the 7 occupational categories, an interesting trend emerged. The average difference between MZ twins was between 0.4 and 0.5 standard deviations at the higher levels of father's occupation and increased slightly to about 0.55 for the lower levels of father's occupation. In contrast, the average difference between DZ twins was around 0.8 standard deviations for the higher occupational levels and dropped down to the same level as the MZ twins for the lower occupational levels. In other words, within pair similarity for the MZ twins stays relatively constant across levels of father's occupational status, but DZ twins become increasingly more similar (and approach the magnitude of the MZ resemblance) for general cognitive ability as father's occupational status goes down. Bivariate DF analyses supported the findings of this simple means analysis and suggested that heritability is significantly higher for general cognitive ability for higher levels of father's occupational status, and shared family environment becomes increasingly relevant for the lower levels of father's occupational status. Similar results showing increased heritability and decreased shared environment as a function of father's educational level have recently been reported in adolescence (Rowe, Jacobson & Van den Oord, in press). This study involved a much larger sample, a larger range for socioeconomic status, and in addition to twins, the study included full and half siblings as well.

How can we explain these preliminary findings? It is possible that heritability increases as environmental opportunities increase and heritability decreases when environmental opportunities are restricted. Individuals are not allowed a free range of choices through which to best express their own preferences. Rowe et al. (in press) suggest that below a certain level, some children are experiencing environments that are deleterious and the lower mean level of intelligence in the lower occupational groups may in part express this negative influence. Conversely, if families fall above this level, the environments are relatively homogeneous in terms of their impact on children's intellectual development and do not play a role in restructuring the causes of individual variation. However, the environments supplied by parent's from higher occupational levels may still have a positive mean effect on their children's IQ.

Clearly these hypotheses are just conjecture at this point and further research designed to measure specific aspects of the environment and/or opportunity is necessary before more definitive conclusions can be drawn.

*General Intelligence and Separable Abilities.* Thus far, this chapter has focused on genetic and environmental influences on general intelligence. A fascinating offshoot from this topic is the exploration of how genes and environment impact on components of 'g' or specific cognitive abilities (Plomin & DeFries, 1998). Detterman and Daniel (1989) discovered a thought-provoking trend when they reanalyzed data collected in the standardization samples for several IQ tests. When the sample was divided into low and high ability groups based on general intelligence, the pattern of correlations among the subtests of each battery differed across low and high groups. Subtests are more highly correlated within low ability groups than they are within high ability groups. Although this study did not address genetic and environmental issues, genetically informative studies may be useful in explaining the origin of these group differences. This finding is especially interesting with respect to the high IQ because it suggests that the structure of general intelligence is fundamentally different among high ability individuals. What is needed are multivariate genetic analyses that investigate the genetic and environmental underpinnings of the structure of intelligence for high and low ability, but this has not as yet been done. This is a completely different issue from the topic described in the previous section concerning changes in heritability and environmentality across levels of intelligence. We return to the topic of multivariate genetic analysis later in this section.

Several studies have addressed the question of whether specific cognitive abilities are differentially heritable with respect to each other and to general intelligence. Specific abilities assessed through standard psychometric tests, for example verbal ability, spatial ability and memory appear to have heritabilities similar to general intelligence and to each other, although the heritability of memory may vary with the type of memory being assessed (Thapar, Petrill & Thompson, 1994). However, studies that have included tests of basic cognitive processing such as reaction times, have suggested differential patterns of heritability across tasks (Petrill, Thompson & Detterman, 1995; Neubauer et al., in press). One of the most interesting yet little known findings about cognitive abilities has emerged from multivariate genetic research, which examines the covariance among specific cognitive abilities rather than the variance of each cognitive ability considered separately: The same genetic factors largely influence different abilities (Petrill, 1997). That is, genetic correlations (the extent to which genetic factors that affect one ability also

affect other abilities) among diverse cognitive abilities are very high, often near unity. These studies include twin analyses in childhood based on WISC-R subtests and specific cognitive ability factors and in adulthood using WAIS-R subtests and specific cognitive ability. Similar results have been reported in sibling and parent-offspring adoption analyses from the Colorado Adoption Project in childhood and in adulthood. The pattern of evidence suggests that genetic influences are responsible for linking together diverse areas of cognitive functioning, whereas environmental effects create differences between different domains.

In other words, the genetic basis of cognitive abilities is general (Petrill, 1997). What this finding means concretely is that if a specific gene were found that is associated with verbal ability, it would also be expected to be associated with spatial ability and other specific cognitive abilities. Conversely,  $g$  should be the best target for attempts to identify genes associated with cognitive abilities because genetic effects are general rather than specific. This finding is surprising because it goes against the tide of the popular modular theory of cognitive neuroscience, which assumes that cognitive processes are specific and independent and that genes work from the bottom up. That is, genes are assumed to be specific to elementary processes, with these modular effects then indirectly affecting more complex cognitive processes. However, multivariate genetic results are consistent with the opposite hypothesis of a top-down model in which genes have their primary influence on  $g$  and these genetic effects trickle down to affect other cognitive processes.

#### *Insights Gained Through Advances in Molecular Genetic Technology*

The field of molecular genetics has made remarkable advances in identifying genes that cause many diseases and physical anomalies; the vast majority of these successful identifications have been rare diseases determined by a single or major gene. The challenge today is to successfully identify genes that contribute to complex or polygenic traits where each gene only contributes to a small portion of the trait variation, also known as quantitative trait loci (QTLs; Plomin, Owen & McGuffin, 1994). Traits of interest to psychologists are likely to involve QTLs including general intelligence, personality, and many common psychiatric disorders. As molecular and statistical genetic methods for detecting QTLs are continually refined, studies searching for QTLs are on a scientific frontier.

There are many unknowns; thus, it is imperative that the trait or phenotype under study be well defined and accurately measured. General intelligence is a strong candidate for this pioneering research with strong social and functional importance as a predictor of academic success. Years of psychometric scrutiny have provided indices of general intelligence with high reliability, validity and stability; quantitative genetic

studies have repeatedly found general intelligence to be heritable. Current advances in neuropsychology and cognitive neuroscience provide a strong biological and structural foundation upon which to bridge the gap between DNA codes and the resulting complex behaviors (Kosslyn & Plomin, in press).

As with many complex traits and diseases, there are several distinct challenges inherent in molecular genetic studies. First, measures of intelligence are continuous and normally distributed. Second, environmental factors account for a significant portion of the variance in intelligence and may make it more difficult to identify genetic effects. And finally as previously mentioned, because of the multiple genes involved, each gene will only have a small effect size thus requiring tremendous power to detect QTLs.

The likely effect size for QTLs important for general intelligence is around 1–2% of the variance. Traditional genetic methods that capitalize on the genetic similarities and differences among relatives like linkage analysis used for identifying single-gene effects are not powerful enough for such small effects (Risch & Merikangas, 1996). Even the newer QTL linkage methods which have been used to successfully identify and replicate linkage for reading disability on chromosome 6 (Cardon, et al., 1994; Grigorenko et al., 1997; Fisher et al., 1999; Gayan et al., 1999) must have an effect size of at least 10% for reliable detection.

Given the limitations of linkage studies, allelic association studies provide an attractive alternative. Unlike linkage studies, allelic association does not require related individuals; instead, it compares the differences in the frequencies of specific alleles between a target or affected group and an unrelated control group. One drawback to association studies is the need for DNA markers to be so close to the functional gene that the marker and gene are not separated by recombination. Therefore two options emerge for the successful identification of a relevant gene. Studies use either only candidate genes, known genes with a high probability of effect, or many, many markers in an effort to screen for relevant genes. To systematically scan the entire human genome for a relevant gene through association analysis, approximately 3500 DNA markers would be needed, a huge undertaking!

However, a line of ongoing research, called the IQ QTL Project, is attempting to do just that using a technique called DNA pooling (Fisher et al., 1999). The goal of the research is to locate genes that contribute to the highest end of the distribution for general intelligence. The strategy maximizes the chance for the identification of genes relevant for the entire distribution of intelligence because those individuals with high intelligence are most likely to have the highest proportion of alleles from the group of genes affecting intelligence, that lead to an increase in intelligence. In contrast, individuals from the low end

of the distribution for intelligence may have a higher proportion of decreasing alleles, but may also be affected by idiosyncratic genetic and environmental factors that disrupt normal development and may obscure the effect of the QTLs relevant for normal variation. Analogous idiosyncratic effects that would impact on a group selected from the high end of the distribution seem less likely.

Because of the multiple comparisons required in an association study with 3500 markers, inflation of Type I error is an inherent problem. To compensate for this inflation, a replication design was used in the IQ QTL Project. An original high intelligence group ( $N=51$ , mean IQ = 136,  $SD=9.3$ ) was compared with a control sample ( $N=51$ , mean IQ = 103,  $SD=5.6$ ).

The IQ QTL Project attempted a preliminary search using a dense map of DNA markers associated with intelligence on the long arm of chromosome 6. For one marker, the frequency of one of its alleles was twice as high in two groups of children with high  $g$  as compared to two groups of children with average  $g$  (frequencies of about 30% vs. 15%, respectively). Both samples yielded a significant difference in the same direction and combining these results yielded a highly significant result ( $\chi^2=12.41$ ,  $p<0.0004$ ). The DNA marker happened to be in the 3' untranslated region of the gene for insulin-like growth factor receptor-2 (IGF2R), which has recently been shown to be especially active in brain regions most involved in learning and memory (Wickelgren, 1998).

Pooling DNA from subjects within each group and comparing the pooled DNA across groups for a dense map of DNA markers offers a solution to the conundrum that linkage is systematic, but not powerful, whereas allelic association is powerful but not systematic. DNA pooling can be used to screen thousands of DNA markers for QTL associations by creating pools of DNA for cases and controls. For example, only 7,000 rather than 1.4 million genotypings would be needed in the previous example for screening 3,500 markers for two groups. An approach to DNA pooling has been developed in the IQ QTL Project that compares the allele image patterns (AIPs) from an automated DNA sequencer for two pools of DNA (Daniels et al., 1998). DNA pooling has been shown to be a reasonably accurate screening tool to detect the largest allelic frequency differences between two groups. A three-stage design in which pooled DNA is compared for an original sample and tested in a replication sample and then surviving markers are individually genotyped and tested using conventional statistics. The goal of this programme of research is to identify some of the oldest and largest QTLs, knowing that QTLs with complicated linkage disequilibrium histories and QTLs whose effect sizes are too small will be missed. DNA pooling is a screening device that greatly reduces the amount of genotyping needed to conduct a genome scan for allelic association using a

dense marker map. DNA pooling results have been reported for 147 markers on chromosome 4 (Fisher et al., 1999) and for 66 markers on chromosome 22 (Hill et al., 1999). Three replicated associations on chromosome 4 were identified using DNA pooling and confirmed using individual genotyping. Encouraged by these first results of the application of DNA pooling for a systematic analysis of allelic association screening a dense map of markers, the IQ QTL Project is proceeding with a scan of 3,500 markers across the genome to find other QTLs for  $g$ . As specific genes are identified, their function can be investigated, not only at the biological level of cells, but also at the neuroscience level of the brain, as well as the psychological level of behavior.

#### *Where do we go from here?*

General intelligence has proven to be a valuable phenotype for both quantitative and molecular geneticists. Despite the fact that intelligence is a complex trait influenced by both genes and environment, quantitative geneticists have demonstrated that individual differences in intelligence are highly heritable, and molecular geneticists are beginning to identify genes associated with intelligence. The entire 'package' of studies that have over the years explored variation in intelligence serves as a model for researchers tackling other complex traits. The search for factors that influence individual differences in intelligence has been a successful journey, but the journey is far from complete. Recent technological, methodological and conceptual advances have opened the door for additional topics of study; we would like to suggest three areas that are ripe for further research on intelligence.

Neuroscience is making rapid advances in our understanding of the structure and function of the brain; as more and more studies begin to pinpoint how cognitive processes operate in general at a neurological level, the potential for extending these findings to the exploration of individual differences is enormous. As measures become more reliable, and as technology becomes more efficient and affordable, we should begin to concentrate on filling in the gap between the gene code at the level of DNA and behavior. For example, cognitive neuroscientists have used functional magnetic resonance imaging (fMRI), high resolution electroencephalogram (EEG) recordings, and positron emission tomography (PET) studies to characterize and localize neurologic processes involved in different types of memory. Quantitative genetic studies have for the most part lumped different types of memory measures into one generic category and molecular genetic studies of memory have yet to be tackled. Given the varying neurologic substrates of different types of memory, quantitative and molecular genetic studies should capitalize on this knowledge and begin to investigate neurologically defined measures of memory.

Although we have gained a considerable amount of knowledge about the nature of environmental factors that affect intelligence, we have not yet realized an understanding of how specific environmental factors, in the normal range, impact on individual variation in intelligence. Developmental studies and the recent finding by Thompson et al. (1999) and Rowe et al. (in press) that heritability decreased and shared environment increased with socioeconomic status suggests that shared environmental factors that impact on general intelligence may be stronger during childhood and in specific groups of families. Identifying systematic non-shared environmental influences that affect variation in intelligence may be quite difficult if Jensen's hypothesis is true and each small piece of the environment operates like one gene in a highly polygenic trait. Perhaps an extreme group association analysis strategy similar to the IQ QTL Project can be adapted using environmental markers in place of, or in addition to, genetic markers.

Psychologists continue to refine and improve indices of personality and emotion; a growing area of research today is in the understanding of the biology of personality and emotion. One of the most frequent criticisms of research on intelligence is that knowing someone's IQ seems to be only a partial predictor of their academic and/or career success. The mediation of intelligence through individual differences in personality and affect may partially address this weakness. Bivariate quantitative genetic analyses could be quite interesting in understanding how these areas are intertwined at a genetic and environmental level particularly when the phenotypes used in the analysis have a strong biological foundation. This approach might be especially fruitful when a child exhibits a large discrepancy between intelligence and global scholastic achievement.

These three suggestions for future research represent only a small fraction of potential research questions ripe for addressing given our current understanding of the genetics of intelligence.

# Giftedness, Expertise, and (Exceptional) Performance: A Developmental Perspective

Wolfgang Schneider<sup>1</sup>

## Introduction

This chapter focuses on determinants of exceptional performance; in particular, the roles of intellectual abilities and domain-specific knowledge in predicting academic and professional success are carefully analyzed. Since the beginning of this century, educational researchers and psychologists have investigated long-term effects of early giftedness and a rich knowledge base to locate the sources of outstanding (academic) behavior and performance. A major purpose of this chapter is to give an overview of the findings of this research.

In a first section, developmental (longitudinal) research on giftedness and its impact on later performance is summarized. This paradigm—which has been used for a long time—is based on the psychometric approach; the next major section focuses on research on knowledge acquisition that has been conducted within the information processing framework. Theoretical models of skill acquisition are briefly described, followed by a review of recent empirical studies on the development of expertise and its relationship to (exceptional) cognitive performance. Finally, theoretical models that describe possible relationships between aptitude and the acquisition of expertise are briefly discussed.

## The Relationship between Giftedness and Exceptional Performance

Although the question of whether early giftedness predicts outstanding academic achievement and subsequent professional success has been repeatedly examined in the literature, the number of longitudinal studies devoted to this issue is still rather small. Most information on the development of gifted children stems from prospective studies where participants are recruited at an early age and then followed through childhood and adolescence (in some rare cases even up

to adulthood). Retrospective studies represent another interesting approach: here, eminent adults are selected for further study which consists of a careful analysis of their biography; the main goal is to identify early signs of subsequent exceptional performance. The findings of classic prospective and retrospective studies are summarized next.

## Prospective Studies

There is little doubt that the well-known Terman Gifted Children Study (Terman, 1954) can be conceived as the most impressive attempt to explore the predictive power of high intellectual ability for subsequent academic performance and success in later life. In fact, the Terman study is the longest prospective study ever conducted; about 1500 young Californian children with an IQ of 135 and above (IQ range: 135–201; mean IQ: 151) were recruited in 1921 and followed until recently. The last questionnaires were sent to the participants in 1996 and answered by a total of 264 men and women (see Hastorf, 1997). Accordingly, this life-span longitudinal study created an enormous and invaluable body of information on developmental changes in gifted individuals.

One of Terman's main goals at the beginning of the study was to prove the assumption that the children in his sample were not only intellectually gifted but also above average in physical and social development. The findings supported this hypothesis and clearly pleased Terman, for he was motivated to disprove the popular belief of the time that high-IQ children are physically awkward and social misfits (see Rost, 1993, for a recent replication of these results). Although the theoretical focus of the study changed over the years, the body of data seems suited to evaluate the relevance of high aptitude for academic and professional performance. The vast majority of children (85%) were accelerated, and nearly half learned to read before entering school (Terman, 1954); as noted by Winner (1996a), early reading is a reliable sign of a high IQ. In accord with this, those 'Termites' with IQs above 170 were more than twice as likely to have read before the age of four than those with IQs below 170 (see

<sup>1</sup> University of Würzburg, Germany.  
E-mail: psy4020@rzbox.uni-wuerzburg.de or  
psy4020@mail.uni-wuerzburg.de

Hollingsworth, 1942, for additional evidence regarding early reading skills in profoundly gifted children).

Terman and his colleagues found that participants' IQs remained high over the course of the study and that IQ differences were stable over time. They also reported that academic achievement of this special sample was clearly superior. Whereas in the general population of California at that time only 8% had graduated from college, about 70% of the male and 67% of the female Termites were college graduates (cf. Hastorf, 1997). Overall, they were also rather successful in later life. However, a closer look at the findings of the Terman study reveals that the expected collection of 'eggheads' and outstanding personalities was not found (cf. Sears, 1984). As noted by Howe (1982), the data collected by Terman and his colleagues provided little information that would have helped one to predict which of the children under study would be most successful in later life. When the small subgroup of children with IQs over 180 were compared to a small group chosen at random, no marked differences in accomplishment were found (Feldman, 1984). Although most Termites became respected professionals, not a single one grew up to become a creative genius. It seems ironic in this regard that two future Nobel laureates, William Shockley, who invented the transistor, and Luis Alvarez, who won the prize in physics, were actually rejected from the study because their IQs did not test high enough (cf. Winner, 1996a). Overall, the conclusion to be drawn from the Terman study is that even though most gifted children turn out to be academically successful, individual differences in giftedness do not sufficiently predict differences in educational achievement and subsequent professional success. A similar finding was reported by Subotnik, Kassin, Summers and Wasser 1993. Although several contemporary prospective studies on high IQ gifted children exist (e.g. Heller, 1991; Rost, 1993; for reports on these and other longitudinal studies, see Subotnik & Arnold, 1994), their findings confirm those outlined above and thus are in accord with our general conclusion.

Further research conducted with random samples of people indicated that the importance of the IQ predictor does not change much when aptitude is assessed considerably later, that is, during the college years (cf. Samson, Grane, Weinstein & Walberg, 1984). In this study, an average correlation of about 0.15 was found between college students' aptitude and their professional productivity assessed several years later, indicating that the subsamples representing 'schoolhouse giftedness' and 'production giftedness' do not have much in common (cf. Siegler & Kotovsky, 1986). Obviously, information about intellectual ability alone does not allow for reliable predictions of later academic and professional success. Given that one major incentive of research in giftedness was to illustrate the importance of early talent and potential for further

development, such an outcome may have contributed to what Weinert & Waldmann (1986) called a 'worldwide crisis' in this research program. Given that the correlations between early giftedness and later professional success obtained from prospective studies were only moderate, it seemed necessary to complement prospective studies with retrospective analyses, thereby exploring the determinants of outstanding professional success.

#### *Retrospective Studies*

Several reanalyses based on the data of the Terman longitudinal study explored the reasons for individual differences in academic and professional success among those intellectually gifted individuals. Oden (1968) assessed occupational success in a subgroup of 664 male Termites and compared 100 of the most successful (given an A rating) with 100 of the least successful (given a C rating). The two extreme groups were found to differ only by seven IQ points: the more successful averaged IQs of 157, and the less successful averaged IQs of 150. However, the A group was much more successful academically, with a high percentage (63%) graduating from college with honors. In comparison, only 11% of the C group graduated with honors. Where the two groups really differed was in their childhood ratings of motivation. The A group was described as more persevering, having greater self-confidence, and engaged in more extra-curricular activities.

Another secondary analysis of the Terman longitudinal study (Elder, Pavalko & Hastings, 1991) revealed that the picture may be more complex. In particular, Elder et al. (1991) explored how major historical events such as the Great Depression and World War II affected the life course of the male Termites. The wide range of birth years of these men placed them in two general birth cohorts relative to historical events: the older with birth dates of 1904 through 1910, and the younger with birth years mainly from 1911 through 1917. The reanalysis by Elder and colleagues illustrates that the two cohorts encountered the Great Depression and World War II at very different points in their life course. The older men were in their early 20s at the time of the economic collapse and thus experienced many problems when completing college and establishing careers. By comparison, the younger men largely missed the economic stagnation of the 30s and could complete their higher education before they were mobilized into the military service during World War II. Thus worklife disadvantages of the older cohort may be partly responsible for the fact that men in this cohort were more likely to end up in the low achievement group (the C group).

Another line of research focused on subjects with reliably superior performances, with the goal to reconstruct their cognitive and non-cognitive abilities. Most of that research was similarly motivated by the

belief that exceptionally high levels of performance should reflect some basic cognitive ability such as general intelligence, attention, or memory (e.g. Cox, 1926). Some researchers studied other stable individual characteristics, such as aspects of personality and motivation (Roe, 1952, 1953). In short, the results of these retrospective studies seem to confirm the outcomes of the prospective studies in that individual differences in intellectual abilities were not the crucial determinant of outstanding professional careers. For example, Roe's analysis of the careers of outstanding scientists showed that non-cognitive factors like endurance, concentration power, and commitment to work were more important for professional success than the individuals' cognitive abilities, despite the fact that the latter were generally above average.

Roe's findings were confirmed in an interview study with outstanding scientists, sportsmen, and artists organized by Bloom (1985a). The data obtained from these subjects and their parents did not support the view that outstanding basic abilities were solely responsible for success in later life. Instead, the study provided strong evidence that no matter what the initial gifts or basic abilities of the individuals, extreme levels of capabilities in their fields of expertise were not attained unless there was a long and intensive process of encouragement, education, and training. Bloom concluded from these findings that his research raised serious questions about earlier views of special gifts and innate aptitudes as necessary prerequisites of talent development (1985, p.3).

Taken together, prospective and retrospective studies focusing on the impact of intelligence and other stable cognitive factors on academic and professional success have been largely unsuccessful in identifying strong and replicable relations (see Ericsson & Smith, 1991, for more evidence on this issue). Instead, most of these studies have shown that non-cognitive factors such as motivation, concentration, and endurance as well as parental and school support systems seem mainly responsible for exceptional performances in later life. However, please note that none of this evidence rules out the possible role of innate gifts.

### The Expertise Approach

#### *Studies with Adult Experts and Novices*

Undoubtedly, the pioneering work on chess conducted by de Groot (1946/1978) and Chase & Simon (1973) has stimulated numerous studies on the nature of expertise. For most cognitive psychologists, an approach based on acquired characteristics seems much more suited to account for outstanding and superior performance than research on giftedness relying on stable inherited characteristics. The game of chess appears particularly attractive for researchers interested in the preconditions of outstanding performance because it is rather easy to produce and observe

outstanding chess performance under standardized conditions. In addition it is possible to measure a subject's chess-playing ability from the results of matches against different opponents in different tournaments (cf. the index developed by Elo, 1978). Another related advantage is that chess players can be reliably differentiated by skill level. As chess skill can be measured with remarkable precision, the domain of chess seems ideal for the study of acquired skill, and models of chess skill have strongly influenced investigations of expertise in other domains such as physics, medical sciences, music, and sports.

One of the major outcomes of the chess studies was that exceptional performance was closely linked with exceptional memory for domain specific information. In order to capture skill differences in chess, de Groot (1946/1978) used a task that assessed memory for briefly presented chess positions. He found that when chess masters were shown a chess position consisting of 20–30 pieces for a very brief duration (e.g. 5 seconds), they were able to remember the position far better than less experienced chess experts. Chess masters were able to recall the positions of all pieces virtually perfectly, whereas the less experienced chess experts recalled between 50 to 70% of the positions. Chase & Simon (1973) followed up de Groot's finding by adding an important control—showing random arrangements of pieces; the experts' advantage in recall with structured positions disappeared.

In order to understand the chess masters' recall superiority for meaningful chess positions, Chase and Simon attempted to uncover the structure of their chess knowledge. They showed that superior recall depended on the master's ability to recognize familiar patterns or 'chunks'. That is, the master was able to recall pieces more effectively than the novice because groups of pieces, rather than single pieces, formed his chunks. According to this finding, quantitative differences in the memory performance of experts and novices could be largely explained by *qualitative differences* in memory behavior.

More recent, carefully designed studies of superior memory performance for chess positions have shown that experts store information about chess positions in long-term memory, not solely in short-term memory as Chase & Simon (1973) originally proposed (for a review, see Charness, 1991). These findings do not negate the basic assumption that there are qualitative differences in memory behavior of experts and novices. They indicate instead that Chase & Simon's (1973) original theoretical assumptions need to be replaced by more sophisticated views of skilled memory such as those by Chase & Ericsson (1982; see also Ericsson & Staszewski, 1989), stressing the importance of domain-specific, easily activated retrieval structures in recall performance.

Qualitative differences in the problem-solving and memory behavior of experts and novices have also

been reported for other domains such as physics, medical diagnosis, reasoning, and sports (see Voss, Vesonder & Spilich, 1980; Chi, Glaser & Rees, 1981; Lesgold, 1984; Morris, Tweedy & Gruneberg, 1985; Anzai, 1991; Patel & Groen, 1991). Overall, a broad variety of studies based on the expert-novice approach have found evidence supporting a monotonic relation between recall of domain-related information and domain-specific knowledge. They have also supported the view that the main differences among experts and novices in a wide range of domains concern the speed of access to relevant knowledge as well as the sophistication of knowledge-based strategies.

### The Acquisition Of Expertise

As emphasized by Ornstein & Naus (1985), an association between expert-novice status in a particular area and differential patterns of performance on tasks related to the area of expertise does not constitute an explanation of how such differences arise. Theoretical models describing the acquisition of expertise are helpful in clarifying the issue.

Several models of skill acquisition are described in the literature; the classic model developed by Fitts & Posner (1967) proposed three different acquisition stages: the 'cognitive stage' can be characterized by an effort to understand the task demands and to distinguish between important and unimportant aspects of the task. The focus is on the acquisition of declarative knowledge about the task. The 'associative stage' involves making the cognitive processes more efficient to allow rapid retrieval, thus transforming declarative knowledge into procedural forms. During the third and final phase, labeled the 'autonomous stage', performance is automatic, and conscious cognition and control is minimal (see Ackerman, 1987, 1988, and Anderson, 1982, for similar theoretical models).

According to these models, practice plays a crucial role in the acquisition of expertise; across a wide range of tasks, improvements in performance seem closely related to the amount of practice. Reviews of skills acquisition indicate that the relationship between performance is monotonic, and that a power function provides a very good fit for a variety of tasks and skills (Newell & Rosenbloom, 1981; Anderson, 1982).

Although these models of skill acquisition have been attractive for many researchers in the field, stimulating much important research, it remains unclear whether the learning mechanisms and developmental stages they propose generalize from adult learners to children. We know from numerous reports on the careers of chess experts, eminent musicians, or world-class tennis players that these individuals started their careers early, that is, between 6 and 10 years of age (e.g. Bloom, 1985a). We also know from several sources that it takes about 10 years between experts' first experiences with their domain of interest to attain international-level performance (Chase & Simon, 1973; Krogius, 1976;

Sosniak, 1985). This '10-year rule' first established by Simon and Chase (1973) for the area of chess, is supported by data from a wide range of domains, including sports, music, and science.

Given that the attainment of exceptional performance in real life usually takes place in childhood and adolescence, it seems important to identify the learning mechanisms, rules of practice, and support systems that enable this rapid development. Research conducted by Anders Ericsson and his colleagues (cf. Ericsson, Krampe & Tesch-Roemer, 1993; Ericsson & Charness, 1994; Ericsson, 1996, 1998) has led the authors to propose a theoretical framework for the acquisition of expert-level performance. The attractiveness of this model stems from the fact that hypotheses about the developmental history and practice intensity of expert-level performers have been systematically evaluated against empirical evidence on exceptional performances in various domains.

### The Role of Deliberate Practice

The model presented by Ericsson and colleagues differs from the skill acquisition models presented above in that it explicitly considers developmental issues within a life-span perspective. Whereas skill acquisition has, for the most part, been studied with college students, most information relevant for Ericsson's theoretical framework stems from observations and retrospective reports dealing with performances in childhood and adolescence.

Ericsson and colleagues adopt and extend the basic characteristics of a framework first developed by Bloom (1985b). According to this framework, the preparation period for reaching exceptional performance can be conceived of as a sequence of states, each representing rather stable characteristics for a specific time period in the individual's life. The first stage corresponds to the playful introduction to the domain, the second to the start of systematic practice supervised by a coach or a teacher, and the third and most crucial stage to attaining exceptional levels of performance (cf. Ericsson et al., 1993).

This model suggests that the type and intensity of training may differ as a function of developmental stage. Whereas it is most important to keep children motivated and interested in the domain during the first stage, methods of instruction and the quality of teachers become more relevant with increasing levels of performance. An early start as well as parental interest and support seem particularly important for the earlier stages. With increasing skill, factors such as availability of excellent instruction, quality of practice equipment, and access to practice facilities become most relevant. As noted by Bloom (1985b), performers at an international level have nearly always been instructed by master teachers who themselves had once achieved that level.

Ericsson and colleagues provide multiple evidence from the domains of chess, sports, music, and arts that is in accord with the core assumptions of this model, and that show surprising parallels in developmental patterns observed across these domains. However, one apparent problem with their early conceptualization (Ericsson et al., 1993) is that it focused on the *extent* of practice, although individual differences in the *intensity or quality* of practice were also observed. Our everyday experiences show that not all people practising and working extensively in a specific domain end up as eminent experts in that area. Thus, there is little doubt that mere experience is insufficient for attainment of very high (expert) levels of performance. More recent descriptions of the theoretical model (e.g. Ericsson et al., 1993; Ericsson, 1996; Ericsson & Lehmann, 1996) addressed this problem by focusing on the role of *deliberate practice*. This term refers to practice activities that aim at maximizing improvement; deliberate practice is conceived of as a highly structured activity that requires effort and is not inherently enjoyable. According to Ericsson and colleagues, individuals are motivated to engage in deliberate practice only because practice improves performance, not because of monetary reward.

Other constraints inherent in the attainment of exceptional performance concern resources, effort, and motivation. In many cases, it has been shown that parental support is a major variable, and that extraordinary commitments by parents may be necessary to cope with the demands (cf. Bloom, 1985b). Further, as deliberate practice requires effort, fatigue is a frequent result; the success of deliberate practice seems to depend on a careful balance of intensive practice and recovery; disregard of recovery may result in maladaptation, injury, and even failure. Finally, as deliberate practice is not inherently enjoyable, motivation has to be given special attention; the loss of motivation can have different causes from problems with external support to temporary stagnation of performance quality. These issues are more pertinent to the initial stages of preparation and may lose their importance when individuals get more involved in a domain. As noted by Ericsson et al. (1993), at this point the motivation to practice becomes closely connected to the goal of becoming an expert performer and integrated into daily routines.

The importance of deliberate practice for attaining expert performance was first demonstrated by Ericsson et al. (1993), who used diaries and interview procedures to study how three groups of elite, adult violinists differing in levels of musical performance spent their daily lives. Whereas the top performance group played at an international level, the second best group was top-rated at the national level; the third group consisted of gifted violinists enrolled in a teacher education program. The musicians in the top performance group were found to spend more time in deliberate practice;

they had spent more practice hours per week than the violinists of the two other groups during early adolescence. From a retrospective estimate of practice, Ericsson et al. (1993) calculated the number of hours of deliberate practice that the different groups of musicians had accumulated until the age of 20. Whereas the best musicians had spent more than 10,000 hours of practice, the number of practice hours for the two less accomplished groups was about 7,500 and 5,000, respectively. The fact that the best violinists were also found to nap more in the afternoon than did the other groups was attributed to the effects of the greater intensity of practice. Since the early work of Ericsson and colleagues, several other studies have found a consistent relation between performance and amount and quality of deliberate practice (cf. Charness, Krampe & Mayr, 1996; Sloboda, 1996; Howe, Davidson & Sloboda, 1998).

One controversial issue emphasized in most of the more recent publications on effects of deliberate practice concerns the explanation of individual differences in expert performances. The core message forwarded by Ericsson and colleagues (as well as by Howe et al.) is that these differences should not be attributed to individual differences in natural, innate (i.e. mainly genetically-based) abilities. Instead, it is argued that expertise has to be conceived of as the result of extensive and intensive practice activities, and that individual differences in ultimate performance can be accounted for by differential amounts of past and current levels of practice. The claim is that once individuals have started deliberate practice, it is virtually impossible to distinguish the role of natural, innate ability from that of acquired skill in their current level of performance. According to Ericsson and colleagues, it is not the innate talent but rather the *perception* of talent that motivates parents to invest time and money to support deliberate practice.

The theoretical framework developed by Ericsson and colleagues seems to account for the causes of exceptional performance. However, the empirical evidence described above mostly consists of cross-sectional studies employing correlational data and are based on retrospective estimates of past behavior and interview data obtained from adults. Prospective studies carried out with child experts and novices may add substantially to our knowledge about the origins and determinants of exceptional performance, particularly as far as the role of domain knowledge and basic abilities is concerned. As a consequence, the empirical evidence on determinants of exceptional performance based on cross-sectional as well as longitudinal developmental studies with child experts and novices will be summarized next.

#### *Studies with Child Experts and Novices*

Most developmental studies using the expert/novice paradigm focused on the impact of domain-specific

knowledge on memory. In the field of memory development, numerous studies conducted during the past two decades have demonstrated the importance of the knowledge base for various aspects of memory performance (for reviews see Chi & Ceci, 1987; Schneider, 1993; Bjorklund & Schneider, 1996; Schneider & Pressley, 1997). According to many developmental researchers, the knowledge base seems to be one of the crucial sources of memory development in childhood and adolescence, probably outweighing other relevant factors such as capacity, strategies, or metamemory (cf. Bjorklund, 1990; Siegler, 1996). Although the number of developmental studies based on the expert/novice paradigm is still small, compared to the number of studies on expertise with adults, the findings have attracted much attention in the developmental literature. In the next section, developmental studies focusing on the role of knowledge will be presented first, followed by those studies that explored the importance of basic ability operating in concert with a knowledge base.

#### *Developmental studies exploring the impact of domain knowledge on performance*

From a developmental perspective, the major advantage of the expert/novice paradigm is that knowledge and chronological age are not necessarily confounded: it is not only possible to recruit adult chess novices but also to find young chess experts for experimental studies. The classic developmental study was conducted by Chi (1978) who recruited experienced and inexperienced chess players and gave them Chase and Simon's chessboard reconstruction task (see above). A most interesting result of this research was that subjects' knowledge correlated negatively with age: Chi found that the children's short-term memory for chess positions was superior to that of the adults. When dealing with a domain (i.e. digits) that adults were more familiar with, typical adult superiority in short-term memory capacity could be demonstrated for the memory span control task. Chi concluded from her results that short-term memory capacity was not inherently a function of the subjects' age, but rather of their knowledge.

From a methodological point of view, both the small sample size of Chi's study and the fact that only two of the four possible groups (i.e. child and adult experts and novices) were included, called for a replication and extension of Chi's work. Two subsequent developmental studies on chess expertise (Roth, 1983; Schneider, Gruber, Gold & Opwis, 1993) found supportive evidence. Roth (1983) did not assess memory performance but tested child and adult experts and novices on a chessboard comparison task. The magnitude of the knowledge effect was sufficient to eliminate any significant differences between child and adult experts. Further, the knowledge effect accounted for between-age group differences in that child experts

outperformed adult novices. Thus Roth's findings for the area of perceptual speed seem to validate Chi's results obtained for short-term memory processes.

Schneider et al. (1993) demonstrated that the more a memory task could be mediated by knowledge of chess, the greater the advantage of child and adult experts relative to novices. Groups of child and adult experts and novices (20 participants per group) were compared on various chessboard and control board reconstruction tasks which included both replications and extensions of Chi's original work. The major extension concerned a procedure that aimed at identifying possible sources of the experts' superior memory performance. Schneider et al. believed that several aspects, such as the experts' greater familiarity with the constellation of chess pieces on the board (i.e. meaning of constellations), and their greater familiarity with the characteristics of the chessboard (i.e. geometrical pattern, form and color of chess pieces), all contributed to superior performance. They expected all these factors to be effective in the meaningful chessboard reconstruction task. It was expected that the effects of expertise on performance would be considerably smaller (but still significant) in the random board reconstruction task because only familiarity with the basic characteristics of the chessboard was assumed to be greater for the experts, as compared to the novices. Finally, no performance differences between experts and novices were expected for a control task that required the reconstruction of wooden pieces on a board that had little in common with a chessboard.

The results of the study basically confirmed these assumptions; similar to the findings by Roth (1983), no performance differences between adult and child experts were found. Expert/novice differences on the chessboard reconstruction task were most pronounced for the meaningful chess positions, and considerably smaller but still significant for the random board positions. In accord with their hypothesis, Schneider et al. found that experts and novices did not differ in immediate reconstruction of items on the control board. They concluded from this finding that experts' performance on the chessboard reconstruction tasks is facilitated by the two context factors described above; probably due to these factors, experts are able to process information faster and in larger semantic units.

The results were inconsistent with those by Chi (1978) and also Chase and Simon (1973) in that no pronounced expert/novice differences in chunking were observed based on inter-response latency measures. The analysis of videotapes suggested qualitative differences in the reconstruction strategies used by the expert and novice groups. Although most experts seemed to start with the reconstruction of specific meaningful units, the novices focused on aspects such as color of pieces or specific positions on the board. From a developmental perspective, it seems partic-

ularly interesting that no qualitative differences in the strategies of the child and adult experts were detected. Regardless of age, however, qualitative differences between experts and novices were found for a chunking measure called the 'collective reconstruction index'. That is, most experts not only picked up chess pieces in a similar order when reconstructing the meaningful chess positions, but also created similar patterns ('chunks'); there were no similar effects for the novices. Thus, the chess studies provided evidence that rich domain knowledge enables a child expert to perform like an adult expert and better than an adult novice, showing the disappearance or even reversal of usual developmental trends.

The importance of practice was illustrated in a follow-up study of the Schneider et al. (1993) chess experiment (Gruber, Renkl & Schneider, 1994); in that study, children were presented with the same chessboard reconstruction tasks they had worked on three years earlier. The most interesting finding was that those children who had lost their expert status because of lack of interest and motivation reconstructed fewer chess positions from memory than those children who had shifted from novice to expert status.

Superior memory performance of child experts has not only been demonstrated in the domain of chess, but also of dinosaurs (Chi & Koeske, 1983), 'Star Wars' (Means & Voss, 1985), and sports such as baseball (Recht & Leslie, 1988) and soccer (Schneider, Körkel & Weinert, 1989, 1990). For instance, Schneider et al. (1989, 1990) proved that the reversal of the usual age effect could be demonstrated for text learning. In this study, about 500 third-, fifth- and seventh-graders were presented with a story about a soccer game, with the participants classifiable as soccer experts and novices. The expected differences between experts and novices were especially evident in the recall and comprehension of the soccer-related passage. Again, a reversal of developmental trends was demonstrated in that third-grade experts recalled significantly more text units than both fifth- and seventh-grade novices; moreover, a re-analysis of the data revealed qualitative differences in the way the soccer-related passage was recalled (Körkel & Schneider, 1992). Whereas experts of all ages recalled more important than unimportant aspects of the text, the soccer novices recalled as much important as unimportant text information, regardless of age. Taken together, the findings from the developmental studies on chess expertise corroborate those obtained from studies dealing with expert/novice differences in adults in that performance differences can be attributed to both quantitative and qualitative differences in information processing.

The developmental studies on expertise discussed above have all demonstrated the rapid development of domain-specific knowledge in child experts and its close relationship to performance in the domain of interest. With the exception of the soccer studies,

however, the variable of ability differences was not included in the design; as a matter of fact, only a small number of developmental studies considered the impact of both intelligence and domain knowledge on performance. These studies will be summarized next.

#### *Developmental Studies Exploring the Impact of Aptitude and Knowledge on Performance*

The assumption that domain-specific expertise can compensate for low overall ability on domain-related cognitive processing was first confirmed in studies that focused on adult populations. For example, Ceci & Liker (1986) demonstrated that adults with IQs in the 80s were capable of complex classification and reasoning processes when the stimuli were highly familiar. Walker (1987) compared high- and low-aptitude adults who were either baseball experts or novices; when presented with a baseball text passage, low-aptitude/high knowledge subjects recalled more than high-aptitude/low knowledge subjects.

Schneider et al. (1989, 1990) proved that this pattern of findings could be generalized to their child soccer experts and novices. When the samples of experts and novices were further subdivided into subgroups of high- and low-aptitude children, neither a single effect was found for psychometric intelligence, nor were there any interactions. This finding was stable over time: when the same children were retested one year later, neither main effects for intelligence nor any significant interactions were found. All in all, the findings of this study suggest that rich domain-specific knowledge can compensate for low overall aptitude on domain-related cognitive tasks. A similar conclusion was drawn by Ericsson et al. (1993) and Howe et al. (1998) from their research on adult expertise. Thus research on exceptional performance in adults and developmental studies on text processing in child experts and novices lead to similar insights, as far as the role of basic abilities is concerned.

Although the evidence seems impressive, findings from more recent studies indicate that some qualification is in order. For instance, aptitude effects on text recall (in addition to those of expertise) were found in studies on text processing when recall was delayed. This indicates that time of testing may be an important variable (Hall & Edmondson, 1992; Visé, 1997). Moreover, developmental studies by Schneider, Bjorklund and colleagues (Schneider & Bjorklund, 1992; Schneider, Bjorklund & Maier-Brückner, 1996) indicated that findings for text processing could not be easily generalized to other memory paradigms such as sort-recall tasks that explored effects of organizational strategies on memory performance. Schneider & Bjorklund (1992) adopted the basic design used by Schneider et al. (1989). However, instead of assessing text processing, they tested second- and fourth-grade soccer experts' and novices' performance on a sort-recall task dealing with soccer words. In accord with

their expectations, Schneider & Bjorklund found significant effects of expertise on recall, thus confirming the results of the previous studies. However, soccer expertise did not modify a significant effect of IQ level, with high-IQ children recalling more than low-IQ children for all contrasts. The results thus demonstrate that domain knowledge played an important role in children's memory, but could not fully eliminate the effects of IQ on sort-recall tasks using domain-related materials. More precisely, although rich domain knowledge seemed to compensate for low aptitude, in that low-aptitude experts performed at the level of high-aptitude novices, its effects were not strong enough to eliminate performance differences between high- and low-aptitude soccer experts.

In a subsequent study, Schneider et al. (1996) confirmed this finding using a within-subject design; in two experiments, both text-recall and sort-recall measures related to the game of soccer were presented to high- and low-aptitude fourth-grade children who were either soccer experts or soccer novices. As a main result, effects of expertise but not of aptitude were found for text recall, whereas both expertise and aptitude predicted performance on the sort-recall task. The authors concluded from this that expertise does reduce but not eliminate the relationship of IQ to memory tasks involving deliberate strategies. Further support for this assumption stems from a study by Gaultney, Bjorklund & Goldstein (1996) who compared strategic memory in highly gifted and intellectually normal children. Gifted children were quicker to identify the advantages of memory strategies, suggesting that one advantage gifted children have on strategic memory tasks is in metamemory.

One problem related to studies with (child) experts is that usually we are not dealing with 'true' (in the sense of exceptional) experts but with knowledgeable individuals who instead may be classified as 'intermediate, semi-experts' or 'subexperts' according to recent classification attempts (cf. Patel & Groen, 1991). To my knowledge, only two developmental studies with 'true' child experts (Horgan & Morgan, 1990; Schneider, Bös & Rieder, 1993; Bös & Schneider, 1997) exist that allow for both a test of the 'deliberate practice' model and the significance of individual differences in basic abilities for subsequent performance. Both samples were exceptional in that they included elite subgroups. Most of the elite child chess players in Horgan & Morgan's study had skill ratings of 1300 and greater (the mean for all US tournament players of all ages is 1500 and the standard deviation is 200). The Bös & Schneider (1997) study referred to a secondary analysis of longitudinal data on the development of about 100 young (10 to 14-year-old) tennis talents that were collected in the late seventies and early eighties. The database included repeated assessments of basic motor abilities, skill-related tests, psychological tests concerning achievement motivation

and concentration skills, as well as interview data focusing on parental support and amount of practice. The careers of most of these tennis talents were very successful, with about 10% of the sample making it to the top 100 in the world (a few players belonged to the top ten players in the world, and two even gained the number one position).

Both studies provided additional evidence for the crucial importance of experience and motivation, thus providing impressive support for the 'deliberate practice' model developed by Anders Ericsson and colleagues. Horgan and Morgan showed that improvement in chess skill was significantly correlated with experience. Using age and pre-test chess ratings as covariates, the authors demonstrated a close relationship between expertise in terms of games played and post-test chess ratings. In sum, the experienced players played more and won more. Similarly, in the longitudinal study of young tennis talents (Schneider Bös & Rieder, 1993; Bös & Schneider, 1997), results of causal modeling procedures showed that parents' support, the amount and intensity of practice, as well as the level of achievement motivation significantly predicted children's tennis rankings several years later (see Schneider, 1997, for a more detailed account on these findings).

What about the impact of basic abilities in these two studies? The elite subsample in the Horgan and Morgan chess study was given two tasks that tapped general abilities (the Raven's Matrices test and a Piagetian task), and one test of domain-specific skill (the Knight's tour). When stepwise regression analyses on post-test scores were carried out for the elite subsample, pre-test chess skill accounted for about 65% of the variance in chess skill at the end of the study. When the Raven's test was added as a predictor, the amount of variance explained in the dependent variable increased to 77%. Another 10% of the variance were accounted for by the addition of numbers of games played. Horgan and Morgan concluded from this finding that both experience and non-verbal intelligence significantly contribute to improvements in chess skill. As the Piagetian task showed no significant correlation with chess skill in the young elite players, it appears that the type of reasoning assessed in general ability tests such as IQ makes an important difference in this regard.

One interesting aspect of the causal model estimated and tested by Schneider et al. (1993) was that although tennis-specific skills and the amount and intensity of practice accounted for most of the variance in children's tennis rankings several years later, the effects of basic motor abilities on tennis performance could not be ignored. That is, when the basic ability construct was omitted from the model, the model no longer fitted the data. Although individual differences in basic motor abilities were not large in this highly selected sample, they made a difference when it came to predicting individual tennis performance.

Taken together, the findings by Horgan & Morgan (1990) and Schneider et al. (1993) basically confirm the theoretical framework developed by Ericsson and colleagues. They all highlight the importance of deliberate practice in developing domain-specific expertise in children. The results provided by Schneider et al. (1993) additionally prove the significance of parental support systems for skill development. However, neither study supports the assumption that individual differences in basic ability can be completely neglected when it comes to predicting the development of expertise.

### **How to Reach Exceptional Performance: Concluding Remarks on Restrictions of the 'Deliberate Practice' Model and the Need for Alternative Theoretical Approaches**

The evidence presented in this chapter clearly indicates that highly gifted children do not necessarily become famous and eminent adults. Although giftedness is usually seen as synonymous with high creativity and professional success, the available research does not support this causal link. In fact, case studies on gifted children, even prodigies, indicate that many of them burn out early, whereas others move on to other areas of interest (cf. Winner, 1996b). More recent research on the development of expertise has shown that exceptional performance is usually based on an extremely rich knowledge base, acquired through a very long lasting process of motivated learning. In order to reach this point, cognitive personality characteristics such as high intellectual ability seem less important than non-cognitive factors such as endurance, dedication, concentration, and motivation. The most important accomplishment of the skilled memory theory was to highlight and demonstrate the relevance of acquired skills in explaining exceptional performance. Later on, the development of the 'deliberate practice' model (cf. Ericsson, 1996, 1998; Howe et al., 1998) provided a framework suitable to describe and explain developmental changes in highly knowledgeable individuals. The developmental evidence clearly supports the assumptions made by Anders Ericsson, Michael Howe and their colleagues that individual differences in the amount of deliberate practice and motivation are key variables for predicting individual differences in the level of expertise in a given domain among high-ability individuals. By and large, my own developmental studies and others conducted in different areas such as soccer, tennis, and chess support the 'deliberate practice' model, thereby underlining the great merit and generalizability of the approach developed by Ericsson, Howe, and colleagues.

Although I can agree with basic assumptions of the deliberate practice model, its position regarding the negligible impact of basic ability differences seems too extreme. See Sternberg (1996), for a sophisticated elaboration on various biases and weaknesses of the

expertise approach. One problem with most of the studies on adult expertise was that individual differences in basic intellectual abilities were not explicitly measured. Given the evidence from developmental studies on expertise that took those abilities into account, one is inclined to believe that the impact of individual differences in basic (intellectual) abilities cannot be completely ignored in theoretical models dealing with the acquisition of expertise. Although the evidence provided by Ericsson and colleagues clearly demonstrates the role of motivation, commitment, and hard work, it fails to rule out the possibility that innate talent plays a necessary role in high achievement (Sternberg, 1996; Winner, 1996b).

The impact of aptitude on cognitive performance most clearly shows up in the case of globally gifted children such as Michael Kearney, a child prodigy who has attracted considerable media attention recently because of his outstanding development (see Kearney & Kearney, 1995; Morelock, 1995). The development of a child who first spoke at the age of four months; began reading single words at the age of eight months; and proved the commutative, associative, and identity rules at the age of three years is difficult to explain by the core assumptions of the deliberate practice approach.

Given that prodigies such as Michael do exist and that their number is increasing, the tendency of promoters of the deliberate practice model to either ignore or doubt the existence of such early exceptional performance is not acceptable. In particular, the statement that objective data are not available in such cases (cf. Ericsson, 1998; Howe et al., 1998) can be easily rejected. For instance, Ericsson (1998) questioned the reports on Jonathan Estrada's precocious speaking and reading performance by noting that the data were provided by the parents without any independent testing by scientists. When I contacted Estrada's parents, I was told that family videos about the then one-year-old Jonathan exist that show him reading picture books, and that Jonathan was tested by a child psychologist at the age of two-and-a-half (Mary Estrada, personal communication, August 1, 1999). Although it may be true that many other prodigies have not been tested at the extremely young age at which they started to speak or read, there is simply no reason to doubt parents' retrospective accounts. As I noted in an earlier comment on the issue (Schneider, 1998), it is difficult to understand why such reports should be less reliable than the recollections of adult musicians concerning their early practice habits, information that is taken as valid by the promoters of the 'deliberate practice' approach.

Another point frequently raised by researchers questioning the impact of genetically-based influences on accelerated development is that rapid cognitive development in the early years is not 'innate' but mainly due to the impact of supportive environmental

conditions. Although careful explorations of the role of family context in the case of profoundly gifted children show that family support is indeed important (see Morelock, 1995, for an impressive documentation), there is no reason to believe that early cognitive acceleration is mainly caused by parental stimulation. As noted by several researchers, one typical feature of highly gifted children is their obsessive desire to master a domain (Feldman, 1991; Morelock & Feldman, 1991). It is difficult to attribute their persistence, drive, and rage to learn and master solely to the specific conditions and supportive features of their environment. Extremely gifted children such as Michael Kearney or Jonathan Estrada can be characterized as stimulus seekers: if they are not sufficiently stimulated, they will produce stimulation for themselves with activity (Winner, 1996a).

Also, the fact that profoundly gifted children maintain their rapid development is well documented and can easily be proven (e.g. Kearney & Kearney, 1995). For instance, Michael Kearney is listed in the Guinness Book of World Records four times: (1) as the youngest person in history to receive a high school diploma (at age 6 years 5 months); (2) as the youngest person in history to enter college (at age 6 years 7 months); (3) as the youngest person in history to have graduated from college (at age 10 years 4 months), and (4) as the youngest person in history to receive a Master's degree (in biochemistry from Middle Tennessee Southern University at the age of 14 years in August, 1998). These impressive accomplishments and the fact that he is a top expert in several domains is difficult to reconcile with the 'ten-year rule' and the environmentalist position of the 'deliberate practice' approach. This is not to question the overall validity and utility of this approach, but just to emphasize the need to qualify and restrict its applicability.

Given that individual differences in basic ability cannot be completely ignored, I suggested a modification of the theoretical framework of expert performance (see Schneider, 1997). I proposed that two different models of exceptional performance explicitly consider the interplay between domain knowledge and basic abilities: a 'threshold' model and a 'partial compensation model'. The 'threshold' model can be described as follows: If the ability parameter of an individual person is close to or beyond a critical or 'threshold' value of ability (typically assumed to be slightly above average), then individual differences in non-cognitive variables such as commitment, endurance, concentration, or motivation determine peak performance. In other words, if the ability score of a given person exceeds a certain threshold value, it does not matter at all whether this individual is gifted or of only normal intelligence. Although this model appears intuitively plausible, one of its problems lies in the definition of critical or 'threshold' scores for different domains (cf. Weinert, 1992). The boundaries may be

well above average for domains/tasks where complex problem-solving activities and strategy utilization are necessary components, and may be clearly below average for less complex domains or tasks that mainly rely on automatic processes (e.g. pattern recognition processes or text recall). Another problem with the 'threshold' model is that it cannot readily explain why basic abilities contributed to performance differences among the two elite subsamples described by Bös and Schneider (1997) and Horgan & Morgan (1990). In the light of these data, it appears that the 'partial compensation' model seems more appropriate, indicating that expertise reduces the contribution of general ability more and more as the amount of domain knowledge increases. Although the available developmental evidence supports such a view, clearly more research is needed to prove the validity of this theoretical approach.

### Acknowledgments

I am grateful to Ellen Winner for valuable suggestions and to Martha Morelock for providing me with her impressive doctoral dissertation. My knowledge about profoundly gifted children was greatly enhanced through communications with Mary Estrada as well as Michael and Kevin Kearney. Last but not least, thanks are due to David Bjorklund for his helpful comments on a previous version of the chapter.

# Issues in the Cognitive Development of Exceptionally and Profoundly Gifted Individuals

Miraca U. M. Gross<sup>1</sup>

## Introduction

In the first edition of this handbook, Gross (1993b) reviewed a substantial body of research on three groups of extremely gifted individuals: (a) adults who made exceptional contributions to their fields, (b) historical studies of children whose remarkable academic achievements implied cognitive ability substantially beyond the norm, and (c) children who scored at or above IQ 160 on tests of cognitive ability.

This chapter will focus specifically on the third of these groups and will present the key research, particularly from the last decade, on the cognitive development of this population of extremely gifted children and adolescents. This chapter, therefore, should be viewed as an addendum to Gross's chapter in the first edition, building on the findings introduced within it.

## Early Studies of Exceptionally and Profoundly Gifted Children

Many of the difficulties experienced in school by extremely gifted students arise from the lack of awareness, among teachers, of the enormous range of ability within the intellectually gifted population. Whereas teachers of impaired hearing or intellectually disabled students are trained to respond to different levels or degrees of the handicapping condition, teachers of the gifted are rarely given such training. Consequently, many educators assume that the intellectually gifted are a relatively homogeneous group—and, for students in the higher ranges of this group, this misconception frequently leads to misidentification, seriously inadequate curriculum provision, and inappropriate grade placement (Gross, 1993a).

Educators working with hearing impaired students recognise four levels of impairment—mild, moderate, severe and profound (Moores, 1987) while, similarly, the field of special education recognises at least three levels of intellectual disability. The level and type of intervention prescribed for hearing impaired or intel-

lectually disabled students are dictated by the degree of severity of the condition (Payne & Patton, 1981). Few educators would expect a severely or profoundly deaf student to cope, in the regular classroom, with the relatively modest degree of intervention required by the child with a mild or moderate hearing loss. Yet exceptionally and profoundly gifted students are regularly placed in the heterogeneous classroom without access to other students who share their abilities and interests and with little or no curriculum differentiation.

Silverman (1989, p. 71) defines the highly gifted as "those whose advancement is significantly beyond the norm of the gifted." It is important to note, however, that by 'advancement' Silverman refers to aptitude or potential, rather than performance. Research on the school performance of the highly gifted suggests that the considerable majority of these children are required to work, in the regular classroom, at levels several years below their tested achievement (Hollingworth, 1926, 1942; Silverman, 1993; Gross, 1993a). Within the broader classification of 'highly gifted', however, are sub-categories of students with increasingly differentiated cognitive characteristics, and more specific terminologies have been developed to classify and describe these children.

Intellectually gifted children can be classified as mildly, moderately, highly, exceptionally, and profoundly gifted. Levels of intellectual giftedness, as defined by IQ ranges, and the level of prevalence of such children in the general population, appear as follows:

Level	IQ range	Prevalence
Mildly (or basically) gifted	115 – 129	1: – 1:40
Moderately gifted	130 – 144	1:40 – 1:1000
Highly gifted	145 – 159	1:1000 – 1:10,000
Exceptionally gifted	160 – 179	1:10,000 – 1:1 million
Profoundly gifted	180 +	Fewer than 1:1 million

<sup>1</sup> The University of New South Wales, Sydney, Australia.

As discussed in Gross (1993b), the literature on exceptional children over the last century contains a wealth of individual case studies of children whose academic achievements imply cognitive development far in advance of what might be expected for their age. Unfortunately, however, the majority of the earlier studies provide no specific information on the children's intellectual status.

Several larger-scale group studies which have compared children of IQ 160+ with moderately or highly gifted age-peers have focused on aspects of psychosocial development but have paid much less attention to cognitive or academic issues (see, for example, Gallagher, 1958; Selig, 1959; Sheldon, 1959; DeHaan & Havighurst, 1961; Barbe, 1964; Janos, 1983). These, and other studies have made extremely important contributions to our knowledge of the affective development of this population, and have been discussed in Gross (1993b) but will not be outlined in this review of cognitive studies.

The most rigorously conducted and influential study of profoundly gifted children was undertaken by Hollingworth (1942) who analysed current and previous conceptions of intellectual giftedness, described 19 children of IQ 180 and above reported by previous researchers, and described in great detail the intellectual, academic and social development of 12 New York children of IQ 180 and above whom she herself had been studying over 23 years.

Hollingworth found significant differences in both the cognitive and affective development of moderately and extremely gifted children. She defined the IQ range 125–155 as 'socially optimal intelligence' (Hollingworth, 1926) and noted that while children scoring within this range were self-confident, out-going individuals who won the confidence and friendship of classmates, children above IQ 160, were so different from their age-peers that, despite deliberate underachievement for peer acceptance, they frequently suffered from social isolation (Hollingworth, 1931). Hollingworth argued that to ensure the optimisation of their academic potential, as well as healthy social adjustment, extremely gifted children should be placed in full-time grouping with intellectual peers. "In the ordinary elementary school situation, children of IQ 140 waste half their time. Those above IQ 170 waste practically all their time" (Hollingworth, 1942, p. 299).

Silverman and Kearney (1989, 1992) have undertaken longitudinal studies of children in Denver and Maine who score above IQ 170 finding, as did Hollingworth, that these children have unusually advanced cognitive and affective development. Rogers and Silverman (in press) are engaged in possibly the largest-scale study of extremely gifted children yet undertaken—a comprehensive analysis of the cognitive and psychosocial development of 241 children of IQ 160+. Gross has been engaged since 1986 in a

longitudinal study of Australian children scoring IQ 160+, which will continue at least until the children reach adulthood (Gross, 1986, 1992, 1993a, 1994, 1995, 1998a; Gross, in press (a); Gross & Start, 1990). Morelock is engaged in a longitudinal study of children of IQ 180 which includes six children of IQ 200 (Morelock, 1995); findings from all these studies are reported in this chapter.

Exceptionally and profoundly gifted students appear very rarely in the school population; this accounts, in part, for educators' lack of awareness of their needs and characteristics. A contributing cause, however, has been a serious neglect of these groups of children by the research community. Much of the empirical research on exceptionally and profoundly gifted children was undertaken in the years between the 1930s and the early 1960s, but the extremely egalitarian ethos of the 1960s and 1970s did not encourage research into the needs of the extremely gifted, and it is only in recent years that we have seen a revival of interest in this population.

Even this belated concern, however, is discouraged by writers such as Savon-Shepin who claims (incorrectly) that "a child with an IQ of 145 is, in fact, much more similar to a child with an IQ of 100, than is a child with a tested IQ of 55" (1994, p. 146), and Richert, who criticises the practice of "designating degrees of giftedness (which) creates implicit hierarchies (and) engenders elitism within programs" (1997, p. 76). Such criticism is unfortunate; there is an urgent need for further sustained observation of the academic, social and emotional development of children whose extraordinary intellectual abilities should qualify them to make significant contributions to the societies in which they live, provided that their youthful potential is permitted to flower into adult productivity.

The broadening of the concept of giftedness over the last 40 years, (see Gagné's discussion in this book) has led us to view giftedness as much more than intellectual precocity, and it would be simplistic to define intellectual giftedness solely in terms of IQ scores. Nonetheless, the intelligence quotient is a useful index of the relationship (and, in the case of the gifted child, the discrepancy) between mental age and chronological age. A moderately gifted 12-year-old with a mental age of 16 and thus an IQ of approximately 133 is 'out of synch' with her age-peers by a matter of four years before she has even passed through elementary school; however her exceptionally gifted age-mate with a mental age of 20 and an IQ of approximately 167 looks across a chasm of eight years from the age at which she is capable of reasoning to the grade level in which she is likely to be placed on the basis of her chronological age. The IQ can assist us in understanding fundamental differences in mental processing between moderately and highly gifted students.

Benbow & Lubinski (1993) note that the top one per

cent of students in almost any distribution of ability or achievement covers as broad a range as that encompassed by the 2nd to the 98th percentile. Goldstein, Stocking & Godfrey (1999) translate this to IQ scores, showing that the range of scores of children in the top 1% on IQ—from 135 to more than 200—is as broad as the range of scores from the 2nd percentile (IQ 64) to the 98th (IQ 132). Indeed, in terms of intellectual capacity alone, the profoundly gifted student of IQ 190 differs from moderately gifted classmates of IQ 130 to an even greater degree than the latter differ from intellectually disabled students of IQ 70. If they are to come anywhere near to maximising their remarkable intellectual and academic potential, extremely gifted students require an educational program which differs significantly in structure, pace and content from that which might be offered to the moderately gifted.

Exceptionally gifted children comprise a population characterised by their scarcity. The incidence of children scoring at or above IQ 160 on the *Stanford-Binet Intelligence Scale (L-M)*, as predicted by the statistical tables, lies somewhere between 1 in 10,000 and 1 in 30,000 (Marland, 1972), while children scoring above IQ 180 are fewer than one in one million. (It should be noted that the *Stanford-Binet Revision IV* is not regarded as appropriate for the measurement of very high levels of cognitive ability and its publishers, Riverside Press, have endorsed the continued use of the *L-M* for gifted assessment pending the imminent publication of the new *Revision V* (Wasserman, 1997). Over the last 70 years, researchers have repeatedly found that the number of children actually identified in the range 160+ far exceeds the theoretical expectations derived from the normal curve of distribution (Terman, 1925; Burt, 1968; Robinson, 1981; Silverman, 1989; Gross, 1993a); nevertheless, even the most generous over-prediction must acknowledge that these young people comprise an extremely small minority of the child population.

### Differences in Cognitive Functioning

Comparative studies of the cognitive functioning of intellectually gifted and non-gifted children have identified significant differences in cognitive style, cognitive development and cognitive strategy selection between the two populations (Rogers, 1986).

Unfortunately very few large-scale comparative studies have been undertaken of differences between the cognitive functioning of moderately and extremely gifted children. A few such studies are reported here; however, as discussed earlier, exceptionally and profoundly gifted children appear rarely, and much of the evidence for significantly superior cognitive functioning in this group comes from single and (occasionally) multiple case studies. Examples of these are presented below and also in the later section on precocious early development in extremely gifted children.

### Cognitive Style

In terms of cognitive style, defined by Rogers as “consistencies in the unique manner in which a learner acquires or processes information” (1986, p. 19) research consistently finds that intellectually gifted children prefer to study independently rather than in mixed-ability groups, function best within a modality which combines auditory and kinaesthetic learning (auditory input alone is often too slow because of their more rapid learning pace), are intrinsically rather than extrinsically motivated, and dislike being given responsibility for the learning achievements of classmates (Dunn, Dunn & Price, 1981; Ricca, 1984; Ristow and Edeburn, 1985).

In Australia Gross (1997), comparing the motivational orientation of academically gifted 7th grade students with an unselected population of age-peers, also found the gifted students to be significantly more task-oriented, focusing on the task and strategies to master it rather than on the ego-oriented desire for high grades or academic recognition. Similarly in Canada, Kanevsky (1994), comparing differences between the problem solving strategies used by young children of average ability (mean IQ 104) and those used by highly gifted age-peers (mean IQ 153) found ability-related differences in motivational orientation. Highly gifted children were more likely to display intrinsic motivation in enhancing their enjoyment of the problem-solving exercises by monitoring and maintaining the level of challenge available to them, whereas children of average ability appeared more extrinsically motivated by the researcher’s interest in their progress. The Fullerton Study found that intellectually gifted children displayed stronger academic intrinsic motivation at age 7 and 8 than non-gifted age-peers, and showed a stronger orientation to test themselves against challenging and rigorous tasks (Gottfried, Gottfried, Bathurst & Guerin, 1994).

Case studies of exceptionally and profoundly gifted children often identify, as a dominant affective characteristic, a passionate desire to learn more, and improve, in the child’s talent field. The father of one of Morelock’s subjects of IQ 180+ described his son’s hunger for intellectual stimulus as “a rage to learn” (Morelock, 1995). Sally Huang, a phenomenally gifted young mathematician in Gross’s longitudinal study, planned her own program of radical acceleration through elementary and secondary school over a period of five years and, from the age of 8, personally negotiated each grade advancement with her teachers and school principals, explaining her unhappiness and frustration at being stalled in her learning process (Gross, 1993a, 1994, 1998a).

Terman’s ‘study within a study’ which traced the development of those members of the gifted group who scored at or above IQ 170 (Burks, Jensen & Terman, 1930), found that 60% of the extremely gifted boys and

73% of the extremely gifted girls were reported by their teachers and parents as preferring to work or study alone rather than with other students. Terman believed strongly that this preference for working independently reflected a natural cognitive orientation.

This preference for independent study, combined with the sometimes startling differences in the cognitive strategies developed and applied by extremely gifted students which will be discussed below, and the findings of Schunk (1987) that children model on, and learn best from, students of similar ability to themselves, may explain why highly gifted students are often reluctant to act as tutors or assistants to children whose abilities are substantially inferior to their own. Many studies have found that the seeming social isolation and reluctance to assist classmates often displayed by the highly gifted disappear when they are placed in ability grouped or accelerated settings with intellectual peers (Hollingworth, 1926, 1942; Gross, 1993a, 1997, 1998b).

Gross's comparison study of the motivational orientation of academically gifted and unselected students also examined a third group; highly and exceptionally gifted students in a full-time ability grouped setting who were also telescoping the six years of secondary schooling into five years (Gross, 1997). These students were very significantly more task oriented than even the moderately gifted group, and, as the assessment of motivational orientation was made in the first few days of the program, it is probable that their unusual degree of task-orientation pre-dated their enrolment. Indeed, the opportunity to progress at a much faster pace than is usually permitted, within a class of children who are also highly gifted, may be more attractive to students who are intrinsically motivated and stimulated by intellectual challenge than to students who are extrinsically motivated and stimulated by external rewards.

As the program progressed, several of the teachers who worked with this highly gifted class commented on the 'cohort effect' of peer bonding, affectionate guidance and mutual encouragement that swiftly developed among this group of students who were similar in their abilities and interests, were task-oriented rather than ego-involved and had been presented with a common but intellectually challenging goal (Gross, 1998a). Yet many of these children stated that in elementary school, in the heterogeneous classroom, they had preferred to work independently and had actively disliked being required to act as tutors for less able classmates. Collaborative work became a delight, rather than a chore, when the students with whom they were now permitted to work were intellectual peers rather than simply age-mates.

### *Cognitive Development*

A substantial amount of research support exists for the proposal that gifted learners differ from their age-peers of average ability at the age, and pace, at which they

traverse the Piagetian stages of cognitive development: specifically, that while all children experience the stages of cognitive development in the same order, the gifted progress through the stages at significantly accelerated rates, thus reaching the formal operation stage at much earlier ages.

In a study of 25 exceptionally gifted children (IQ 160+) aged 6–11, Webb (1974) found that the entire group had mastered the most complex or advanced tasks at the concrete and (for the older children) formal operations stages significantly in advance of their age-peers. Keating (1975) studying gifted 11-year-olds, found a level of developmental precocity within the Piagetian framework which led him to suggest that it may be more important to think in terms of IQ, rather than age, in predicting children's developmental stages—thus echoing the advice of Hollingworth who advised that mental age, rather than chronological age, should serve as a predictor of children's success in cognitively mediated school subjects (Hollingworth, 1926, 1930).

Some researchers suggest that chronological age does set some limits on stage-to stage progression. Reviewing earlier research, Carter & Kontos (1981) suggested that at the pre-operational stage, gifted and non-gifted children were equal in task performance up to age 6, and that only in the middle years of elementary school does the relationship between IQ and developmental stage become more substantial. Kanevsky, however, found that as early as four years of age, intellectually gifted children were significantly superior to age-peers of average ability in acquiring and generalizing strategies for solving two different versions of the 'Tower of Hanoi' puzzle (Kanevsky, 1992).

Several studies (e.g. DeVries, 1974; Kemler, 1978) suggest that IQ, and mental age, are correlated to certain specific skills *within* each stage of development but not to others, and that this accounts for the differentiated levels of cognitive performance which can be noted in individual children across a range of tasks. Brown, for example, points out that mental age by itself cannot guarantee exceptional performance on those tasks which depend on pre-existing knowledge (Brown, 1978).

It is notable, however, that Holahan & Sears (1995), in the most recent volume reporting the results of Terman's longitudinal study, strongly endorse the validity of mental age as a determinant not only of academic achievement but also of vocational interests, recreational interests and affective development in childhood and adolescence.

"Through the school years and into adolescence these children's interests, attitudes and knowledge developed in correspondence with their mental age rather than with their chronological age. Their academic achievement as measured by tests, their

interest and liking for various future occupational careers, their knowledge about and interest in games, their choice of recreational reading materials, and their moral judgments about hypothetical conduct were all characteristic of older non-gifted children whose mental age-range was approximated by this much younger and brighter group. Even the intellectual level of their collections was more mature than that of their chronological age-mates”.

Holahan and Sears, 1995, p. 16.)

#### *Cognitive Strategy Selection*

A wealth of research is available on ways in which gifted individuals differ from non-gifted in the cognitive strategies they select and use both in structured problem-solving tasks and in their daily lives. Rogers (1986, p. 29) lists the higher-order (meta-componential) information processing strategies which are used more frequently and effectively by the gifted. These include: the swift and spontaneous generation of a series of steps towards the resolution of a problem, the setting of priorities, the systematic monitoring of progress and solutions, a longer period of thoughtful pre-analysis of the problem before beginning the attempt towards its solution, and the representation of information through structures more usually employed by an expert in the field.

Ian Baker, whose ratio IQ on the *Stanford-Binet L-M* is in excess of 200, was fascinated by cartography. By age nine he could identify and classify, in terms of his state's Department of Roads descriptors, any major or minor road in his home city of one million people. He drew maps to demonstrate his theories of how the road systems and traffic flow of various suburbs could be improved and synthesized the bus, train and streetcar timetables produced by the State Transport Authority to provide more effective service linkages (Gross, 1992).

Ian's fascination with structural analysis, and the strongly spatial orientation of his problem-solving strategies, were apparent in every area of his school-work and throughout his leisure pursuits. His parents and teachers were concerned by his reluctance to access or use narrative text. As his mother explained:

“The sort of things that excite him (are) factual books, books on computing or logic, or compendiums of math puzzles. He had a craze, at one stage, for ‘Choose Your Own Adventure’ stories, because he liked working out the different permutations of changes and endings. But even in writing, he doesn't go in for imaginative stories. When he was seven his teacher said to me that she would throw a party on the day he wrote an imaginative story because anything she asked him to do he would convert into a diagram, a maze, a flow-chart, a timetable, calendar—everything had to be set out and analyzed” (Gross, 1992, p. 123–124).

Sternberg (1981) has noted significant differences between gifted and non-gifted learners in tasks involving *analogical* thinking and in the skills of acquisition (learning new information), retention (retrieving information previously required and stored in long-term memory) and transfer (skills in applying various problem-solving heuristics across a range of problems).

Many of the cognitive traits which characterize moderately gifted children appear at even earlier ages, and in heightened or intensified forms, in the highly gifted. Ian Baker is only one of many highly gifted children who have developed, to an unusual degree, Sternberg's ‘transfer components’, the skills required for generalizing concepts from one context to another (Sternberg, 1981). Roedell describes a 4-year-old boy who had been learning about set theory in mathematics. Later, when someone asked him what he wanted to be when he grew up, he said, “Maybe I'll be doctor; no, I think I'll be a fireman”. Then, describing, with his arms, an intersection set, he announced, “No—I'll be a paramedic!” (1989, p. 19). Tessa, aged 8, a highly gifted young musician and a member of Gross's longitudinal study of children of IQ 160+, when seeking to describe her new-found, but deeply important, friendship with two other highly gifted girls, found her metaphor in music “Each of us is a different note—we've each got our own voice and our own qualities—but put us together and it's like a D major chord! Something beautiful and better happens” (Gross, in press (b)).

A keen sense of humour in young children has often been noted as an indicator of intellectual giftedness (Torrance, 1977; Shade, 1991; Harrison, 1999) but the degree of sophistication of that humour increases with the level of ability. Specifically, the analogical reasoning noted by Sternberg (1981) and the capacity to transfer ideas between contexts at early ages and with unusual facility can help to explain the delight in puns and wordplay which seems to characterize extremely gifted children even in the early years.

Silverman (1989) describes the two-year-old who was playing beneath his mother's bed and when told she was trying to have a rest, spontaneously explained, “Does that mean I'm under arrest?” Gross (1995) describes four-year-old Steven whose pre-school teacher, cleaning up after morning recess, asked him to pass the plastic cup which had contained his fruit juice. Steven incurred her wrath by parading solemnly back and forth in front of the cup for several minutes and finally responding to her rebuke by assuring her that he was only doing what she had instructed—he had now passed the glass from several different directions.

A striking characteristic of exceptionally and profoundly gifted children is their capacity for ‘dual focusing’, the ability to process two sets of information simultaneously. Christopher Otway was assessed on the *Stanford-Binet (L-M)* at the age of 11 and passed

virtually every item on the test, right up to Superior Adult Three. He scored at the ceiling of the test; however, a ratio calculation gave him an IQ of 200. The psychologist's assessment included some interesting analyses of Chris's styles of processing information.

“(Christopher) works hard at trying to put every piece of information or every problem which he has to solve into some sort of category. Perhaps at his level of intellectual activity this is the most efficient way of handling the multitude of information and ideas which he handles each day. I have also observed (as have his parents) that Christopher is one of the few people who truly seems to be able to handle information in parallel. For instance, when he was working on quite a difficult question in the assessment, and was obviously thinking and talking on that particular problem, he suddenly interrupted himself to produce the solution to a previous problem which he felt he could improve on.”

(Gross, 1993, p. 15)

Chris's younger brother, Jonathon, who also ceilinged out on the *Stanford-Binet (L-M)* at the age of 8 years 4 months, obtaining a ratio IQ of 170, has a similar cognitive style, although, as the psychologist found, this often manifests itself differently through Jonathon's puckish sense of humor.

“Jonathon's verbal responses (were) of exceptionally high quality. He is a very fluent and articulate sort of child, who has highly developed abstract reasoning skills. It was also obvious that Jonathon has a well-developed sense of humour, too, and often he handled test items on two levels. Firstly he would answer the test question exactly as it was given at a very high level, but then he would give me a supplementary and much more humorous answer or interpretation of the item which he had just completed”.

(Gross, 1993a, p. 17-18)

Lyndall Hendrickson, an Australian music teacher who has taught and mentored several extremely gifted young violinists, has noted this capacity for dual focusing in highly gifted musicians who also possess exceptional levels of cognitive ability. One of many illustrative examples is that of a nine-year-old girl, herself a child prodigy, whom Hendrickson took to hear a recital by another of her students. To Hendrickson's irritation, the child spent her time making detailed sketches of the soloist and other members of the orchestra on a drawing pad which she had brought with her. However, when questioned later on what she had learned from the recital, the young girl offered a reasoned and insightful critique of the performance, including a perceptive analysis of the soloist's phrasing (Hendrickson, 1985).

As can be seen, the cognitive functioning of exceptionally and profoundly gifted children differs in many ways from that of their moderately gifted counterparts. An overview of the early development of extremely gifted children can assist us to understand the origin of these differences.

### Developmental Precocity in Extremely Gifted Children

As discussed earlier, exceptionally and profoundly gifted children appear rarely in the population, and research on extreme intellectual precocity has mainly comprised isolated case studies of individual children. Such group studies as do exist (Gallagher & Crowder, 1957; Barbe, 1964) are generally of short duration. Longitudinal studies which follow the subject group's development through adolescence into adulthood, such as Hollingworth's landmark study of children of IQ 180+ (Hollingworth, 1942), Terman's 'study within a study' of members of the gifted group who scored at or above IQ 170 (Burks, Jensen & Terman, 1930), or Gross's study of children of IQ 160+ (Gross, 1993a et seq.) are extremely rare. Furthermore, many reports of childhood precocity are retrospective, undertaken when the subjects have already attained adulthood, or even after the subject's death (Cox et al., 1926; Montour, 1977; Bergman, 1979).

For a fully accurate picture to be obtained of the cognitive or affective development of extremely gifted children, it is important that their development should be studied not retrospectively but *in current time*. In this way, events and situations which impact on the child's development can be observed as they occur, rather than being recalled by parents, or in adulthood by the subjects themselves, through the filter of an unintentionally biased and selective memory. In the case of exceptionally and profoundly gifted children, whose development may differ radically from that of age-peers, it is particularly important that the young child's perceptions should be recorded at the time when they are influencing his or her thoughts and actions, rather than related in later years.

The case study method is a sound approach for developing specific knowledge about exceptional giftedness; it is ideally suited to the investigation and description of events or people characterised by their rarity (Foster, 1986). It provides a holistic perspective and allows the researcher to develop and validate theories grounded in direct observation of individual students. Indeed, close observation of the student in natural settings, the analysis of subjective factors such as the subject's attitudes, desires and perceptions, and the use of a wide range of observation procedures, all of which are characteristic of good case study research, enable a more comprehensive observation of a subject or process than is possible with any other research methodology (Merriam, 1988).

Nonetheless, the retrospective nature of much of the case study research on the early years of gifted children has led researchers who support a wholly or largely environmental view of giftedness to suggest that records of very early speech, movement or reading may derive from flawed parental memory or inaccurate recording. However, the Fullerton Longitudinal Study of the early years of a group of gifted and non-gifted children has provided empirical evidence of the developmental advancement of intellectually gifted young children (Gottfried, Gottfried, Bathurst & Guerin, 1994).

The Fullerton Study traced the development of 107 children recruited through birth notifications of hospitals adjacent to California State University, Fullerton. The children were full term babies of normal birth-weight who were free of visual and neurological abnormalities. The children, who were one-year-old at the commencement of the study, were given numerous developmental assessments through the first eight years of life. At the age of eight, they were assessed on the *Wechsler Intelligence Scale for Children—Revised (WISC-R)* and the 20 children who made a full-scale IQ score of 130 were designated the gifted group for comparison with the other 87 children. The IQ range in the gifted group was 130–145 with a mean of 137.6; the range in the non-gifted group was 84–128 with a mean of 110.9.

The Fullerton team thus possessed objective, systematically collected, data on the early development of a group of children who were *later* identified as gifted. This is not, therefore, a retrospective study, but a developmental study conducted in current time and the consistent superiority of the gifted group cannot be attributed to flawed memory or parental bias.

Indeed because the mean of the Fullerton comparison group (110.9) is significantly higher than the mean of the general population, the superiority of the gifted group would doubtless be even more striking if the comparison group had included a fuller representation of children of average ability. It is significant that the least able subject in the comparison group scored only slightly more than one standard deviation below the mean of the *WISC-R*.

The Fullerton Study found that differences in the level of intellectual performance between the gifted and non-gifted children appeared on psychometric testing as early as 1.5 years of age, and were sustained throughout the study. Interestingly, the earliest difference was found at age one, *on entrance to the study*, in receptive language. Given the evidence of extremely early responses to speech in young gifted children (e.g. Gross, 1993a) it is interesting to speculate how much earlier this difference might have been recorded if structured observation had been commenced in the first year of life. Significant differences in expressive language were consistently found from infancy onwards. Assessments of comprehension, gross and

fine motor skill, memory, and personal-social development consistently found the gifted group superior. Indeed, the only academic skill on which the gifted children did not display significant superiority was on numeracy—and the researchers noted that this was due to a ceiling effect on the test for the gifted group! Indeed, the Fullerton team concluded: “Gifted IQ implies generalized high intelligence. Gifted children were superior across an array of cognitive tasks beginning as early as the pre-school period. Gifted children tended to be cognitively well rounded or adept. Globality rather than specificity in cognitive performance characterizes intellectual giftedness” (Gottfried, Gottfried, Bathurst & Guerin, 1994, p. 85).

Although, as might be predicted from the relatively small sample size, the Fullerton Study included no extremely gifted children—the highest IQ in the group was 145—its findings do lend credibility to retrospective assessments of unusual cognitive precocity in case studies of the intellectually gifted.

#### *Early Development of Speech and Movement*

Exceptionally and profoundly gifted children differ significantly from their age-peers of average ability both in their cognitive and in their socio-affective development and, as with the subjects of the Fullerton study, these differences generally become evident from their earliest years, with the precocious acquisition of speech and movement. Studies of the early movement of moderately gifted children report that these children learn to walk, on average, two to three months earlier than age-peers (for example Terman, 1925) but, in general, the extremely gifted show even more remarkable physical precocity. Silverman (1989) described a girl of 7 months who stood alone, climbed into chairs unassisted and went up and down stairs by herself. Gross (1993a) describes Rick, of IQ 162, who sat up by himself at four months, ran at 11 months, and rode a two-wheeled bicycle unaided at age three. Six subjects in Gross’s study of children of IQ 160+ were able to sit up unsupported before the age of 5 months, and with only few exceptions the children in this study crawled, walked and ran at ages considerably younger than the population as a whole (Gross, in press (a)). One of the most remarkably precocious is Emma who began horse-riding lessons (at her own urgent insistence) at the age of 14 months and who at 18 months competed in a riding school gymkhana and won second prize in a competition against 12 other junior riders aged between three and seven (Gross, 1999).

Numerous researchers have noted the early development of speech which is characteristic of even moderately gifted children. Jersild (1960) studying the fluency of speech in young children, noted that at the age of 18 months, when children of average ability were uttering a mean number of 1.2 words, per ‘remark’, their gifted age-peers were uttering 3.7 words. By the age of four the difference was even more remarkable;

the mean number of words per 'remark' for average children was 4.6 whereas for the gifted it was 9.5.

Occasionally the speech of even extremely gifted children may be delayed. Probably the best known example of this is Einstein who did not talk until three years of age and who was suspected of being intellectually disabled (Goertzel and Goertzel, 1962). Similarly, the mother of two brothers in Gross's study who did not speak until 18 and 21 months respectively was warned by their pediatrician that they may be seriously developmentally delayed; the brothers later tested at IQ 170 and 200 (Gross, 1993a).

It is important, therefore, that delayed speech should not be taken as indicating that the child is not gifted. Research has shown, however, that very early speech, is a powerful indication of high levels of cognitive ability. A study of 241 children of IQ 160+ found that 91% were reported, by their parents as displaying unusually early language development (Rogers and Silverman, in press). The mean age at which the 58 IQ 160+ subjects of Gross's study uttered their first meaningful word (other than 'mamma-dadda' babble) was 8.7 months.

In general, exceptionally and profoundly gifted children display remarkably complex and advanced speech patterns. The case study literature on the extremely gifted is particularly rich in examples of this (Langenbeck, 1915; Terman & Fenton, 1921; Goldberg, 1934). Hollingworth (1926) reported on 'David' who was talking in sentences at the age of 11 months and who at the age of 8 months exclaimed, "Little boy!" when his shadow appeared on the wall. 'Ian' in Gross's study knew all the words of the song *My Grandfather's Clock* by the age of 23 months, and at 2 years 4 months announced to a family friend, "My father is a mathematician and my mother is a physiotherapist" (Gross, 1993a). Emma, whose unusual motor development was reported on earlier, is also linguistically precocious: by 13 months of age she had a vocabulary of more than 80 words.

The precocious development of movement permits extremely gifted children to move around and explore for themselves much earlier than their age-peers of average ability, while their very early speech enables them to express their ideas, seek information through questioning and interact verbally with their parents and other family members at an age when other children are only beginning to experiment with oral communication. Both early movement and early speech contribute significantly to these children's capacity to acquire and process information. Reading, a third and significant source of knowledge acquisition, also seem to develop at remarkably early ages in the extremely gifted.

#### *Early Development of Reading*

While some researchers question the relationship between early reading and intellectual giftedness (see

Jackson & Klein, 1997 for a discussion of this) there is little doubt that the *extremely* early acquisition of reading is both one of the most powerful indicators of exceptional giftedness and a powerful predictor of later school success. Terman found that one of the few variables on which his IQ 170+ sub-group differed from the moderately and highly gifted subjects was the very early age at which they learned to read (Terman & Oden, 1947) while Hollingworth (1926) confirmed that it was very early reading which most clearly differentiated between moderately and extremely gifted children. All Hollingworth's subjects of IQ 180, read before school entry, while 80% of them read by age four (Hollingworth, 1942).

VanTassel-Baska (1983) studied 270 students aged 13 and 14 who had achieved within the 90th percentile on the Mathematics or Verbal subtests of the *Scholastic Aptitude Test*, and found that 80% of this group had read by age five and 55% by age four. More than 90% of Gross's subjects of IQ 160+ read by age five.

One of the most striking contrasts noted between the gifted and their age-peers of average ability is the age at which different books are read. Terman (1925) noted that books which were preferred by the average child of 11 or 12 were usually read with enjoyment by the moderately gifted child of 8 or 9.

Even more striking differences are noted in the reading interests of moderately and extremely gifted children. Gross (1993b) provided an overview of the literature since the early years of the century on the extremely advanced reading interests of exceptionally and profoundly gifted children. Current research suggests that extremely gifted children still prefer novels and non-fiction texts which are more usually selected by students 5–7 years their senior, and still tend to seek out books which address social and ethical issues, although what Halstead (1988) terms 'high fantasy'—adolescent or adult science fantasy novels, or series of novels, which trace a quest or a seeking for moral maturity by an individual or group—have replaced the classics which served a similar purpose for the highly gifted young people studied by Terman & Hollingworth. The literature on the highly gifted suggests that the majority of extremely gifted students deliberately moderate or conceal their exceptional abilities in the regular classroom in attempts to win social acceptance by age-peers (Hollingworth, 1926, 1942; Pringle, 1970; Silverman, 1993; Morelock, 1995). Gross found that 70% of the early readers in her study deliberately stopped reading, or significantly moderated their *in-class* reading, within the first few weeks to conform to peer expectations (Gross, 1993a). Significantly, however, their passion for reading, and the precocity of their reading abilities and interests was maintained at home.

This deliberate concealment of precocity for peer acceptance can easily be misinterpreted. Braggett (1983) proposed that many children who display

unusually accelerated reading development in early childhood may not retain this capacity but may, rather, be 'developmental spurters' whose early promise is not fulfilled as the child progresses through elementary school. However, the persistence of exceptional reading accuracy and comprehension skill in Gross's Australian subjects of IQ 160+ indicate that these children are by no means 'developmental spurters'. In virtually every case the reading development of these children has followed the pattern reported in the studies of Burks, Jensen & Terman (1930), Hollingworth (1942), Durkin (1966) and VanTassel-Baska (1983), and in the numerous individual case studies of precocious readers (Terman and Fenton, 1921; Witty & Coomer, 1955; Feldman, 1986); that is, the precocity which was such a salient feature of the child's early development has persisted, and in many cases increased, through the children's elementary school years.

What has decreased, however, has been the opportunity for these children to display their reading precocity in the classroom. The majority of these exceptionally gifted children are required to work lock-step through the curriculum at the same level and pace, and using the same school texts and materials, as their chronologically aged peers (Gross, 1998a). Thus, their continuing exceptionality in reading is displayed not in the classroom but at home, or in extra-curricular programs for gifted children organized by universities or advocacy groups, where their unusual reading abilities and reading interests are accepted and valued. In several cases the child has appeared, to his classroom teacher, to have developed a new, and apparently unrelated, gift or talent.

An important insight into the continuity, but transmutability, of precocity in reading is offered by Jackson (1992) who proposes that, since the challenge of learning to read extremely well may lose its excitement as the young gifted child progresses through the early years of school, she may seek other avenues for the expression of her precocious talent for decoding and encoding what is, in essence, a complex and sophisticated symbol system. We have discussed earlier, the unusual capacity of gifted children for generalizing concepts from one context to another. Some precocious readers may translate this facility into an enhanced capacity for learning mathematics or computer programming. In a peer culture which ridicules, rather than values, enhanced linguistic development, the child may deliberately choose to transfer her skills to another area in the hope that this new expression of talent may be accepted more readily by her teacher and classmates.

Rather than assuming that giftedness is transient and that developmental spurters are "possibly the largest single group of gifted children we may identify in the school" (Braggett, 1983, p. 14), we should seek to understand the continuity of giftedness through its

diverse manifestations and transitions as the child matures.

### Multiplicity of Talents in the Extremely Gifted

Models of intelligence which propose a number of specific, quasi-autonomous factors, abilities or aptitudes, for example Thurstone's (1938) seven 'primary mental abilities' or Gardner's (1983) theory of 'multiple intelligences' which bears some interesting parallels to Thurstone's model, require greater empirical support if they are to become the foundation for broad-based educational usage. More recent research has lent substantial support to Spearman's (1904) conception of a general mental ability factor *g*—"a highly general information-processing capacity that facilitates reasoning, problem solving, decision making and other higher order thinking skills" (Gottfredson, 1997, p. 81) and the placement of *g* at the apex of a pyramidal hierarchy of factors which comprises, in its lower layers, broader cognitive abilities which themselves comprise narrower, more specific abilities (Carroll, 1993). As discussed earlier, the Fullerton Study found powerful support for *g* in their study of pre-school children which noted the superiority of the gifted group across a whole range of cognitive tasks (Gottfried, Gottfried, Bathurst & Guerin, 1994).

The extraordinary superiority of extremely gifted children across a wide range of subject fields, and indeed domains gives powerful additional support to *g*. The case study literature over the last 70 years consistently documents children of IQ greater than 160 who have displayed astonishing multiplicity of talents (McElwee, 1934; Goldberg, 1934; Grost, 1970). A not untypical example is 'R', reported by Zorbaugh & Boardman (1936) who was reading omnivorously before school entry and by age eight had a large personal library of books on science, history and biography which he had catalogued himself on the Dewey decimal system. At age two he was modeling in clay and at age three began to design and make machines; he applied through his father to the United States patent office for two patents before he was eight years old; at the same age he was writing a book on electricity.

During the last 30 years reports of single case studies of extremely gifted children have only rarely appeared in journals of gifted education or psychology. One of the very few exceptions has been a report (Gross, 1986) of the academic and socio-affective development of Terence Tao, an Australian boy of IQ 220+ who taught himself to read before his second birthday through watching *Sesame Street*, scored 760 on the *Scholastic Aptitude Test—Mathematics (SAT-M)* at age 8 years 10 months, at nine was teaching one of his younger brothers chess, and the other piano, and at age 12 was amusing himself by translating *The Hitch-Hiker's Guide to the Galaxy* into Latin. Researchers' knowledge of the extremely gifted, and further research

interest in them, would doubtless be enhanced if journals were willing to publish further rigorously conducted and comprehensive single-subject case studies of exceptionally or profoundly gifted children. It takes a researcher many years to locate and study large samples of this sparse population and the ongoing dissemination of research is needed!

The larger scale studies of Hollingworth and Cobb (1928) and Hollingworth (1926, 1942), however, also noted a consistent superiority of exceptionally gifted students over the moderately or highly gifted, over a wide range of subject areas. Hollingworth and Cobb's (1928) 'Public School 165' experiment, in which two classes of gifted children, one centering on IQ 146, the other centering on IQ 165, were given an identical curriculum, taught under identical circumstances, over a period of three years, showed that the IQ 165 group demonstrated superiority across 12 of the 14 areas tested, the sole exceptions being speed and quality of penmanship (handwriting) which are significantly moderated by sensorimotor ability.

Gross's subjects of IQ 160+ almost without exception display remarkable superiority across a range of academic fields and many also excel in music, computing and sport (Gross, 1993a) However both Gross (1992, 1993a, 1998a) and Rogers & Silverman (in press (a)) have found that their subjects of IQ 180+ have even a wider range of exceptionalities and a wider range of interests.

By the time Christopher Otway of IQ 200, was 12 years old he had been accelerated to 9th grade and was undertaking further subject acceleration with 11th grade students in physics, chemistry, maths, English and economics. Because of his unusual aptitude for music he commenced flute lessons with students four years older and while undertaking undergraduate study, played in a prestigious flute ensemble, the majority of whom were musicians of many more years experience. He plays competitive tennis, was until recently the organiser and captain of a mixed-sex netball team, enjoys contract bridge, served on the committee of his university's Science Fiction Club, plays piano, takes a keen interest in the Stock Market and reads voraciously.

Chris entered Grade 10 a few weeks after his 13th birthday but, rather than continuing his subject accelerations to Grade 12, he chose to 'repeat' Grade 11 in different curriculum areas, this time selecting English, legal studies, Australian history, accounting, and biology. The following year he entered Grade 12 and took, for university entrance, the five subjects he had taken in his 'first run' of Grade 11, and the year after that, he 'repeated' Grade 12 and took, for university entrance, his second set of five subjects.

It was Chris's own decision to take this somewhat unusual method of acceleration. He felt that he would not be ready, at age 13 or 14, to enter university and he was delighted with the opportunity to broaden his

education by taking ten, rather than the usual five, subjects at Grade 12 level. Interestingly, in both of his Grade 12 years, he graduated as one of the top students in his state, majoring in mathematics (two subjects), physics, chemistry, economics, English, Australian history, legal studies, accounting and biology.

Chris entered university at 16 and graduated with two degrees, a Bachelor of Economics and a First Class Honours degree in Computer Science and Pure Mathematics, before his 21st birthday. He was successful in winning a scholarship to a prestigious British university and now, aged 23 is in the final year of PhD study.

### Radical Acceleration

"Someone has said that genius is necessarily solitary, since the population is so sparse at the highest levels of mental ability. However, adult genius is mobile and can seek out its own kind. It is in the case of extraordinarily high IQ that the social problem is most acute. If the IQ is 180, the intellectual level at six is almost on a par with the average eleven-year-old and at ten or eleven is not far from that of the average high school graduate... The inevitable result is that the child of IQ 180 has one of the most difficult problems of social adjustment that any human being is ever called upon to meet'

Burks, Jensen & Terman, 1930, p. 264).

Earlier in this chapter a brief review of the literature on the extremely gifted established the difficulties that arise when the differences between extremely gifted children and their age-peers so far outweigh the similarities as to hinder the formation of productive social relationships. Hollingworth identified an IQ of 160 as being the 'danger point' beyond which the gifted child is particularly at risk for social rejection by age-peers, and noted that the problems of social isolation seemed particularly acute between the ages of 4 and 9 (Hollingworth, 1931).

It cannot be sufficiently emphasized, however, that the problems of social isolation, peer rejection, loneliness and alienation which afflict many extremely gifted children arise *not* out of their exceptional intellectual abilities but as a result of society's response to them (Selig, 1959; Janos, 1983; Gross, 1993a). These problems arise when the school, the education system or the community refuses to create for the extremely gifted child a peer group based not on the accident of chronological age but on a commonality of abilities, interests and values.

The multiplicity of talents displayed by exceptionally and profoundly gifted children, coupled with the social and emotional maturity which characterizes these young people (Terman, 1925; Hollingworth, 1942; Janos, Robinson & Lunneborg, 1989; Gross, 1993a) makes them excellent candidates for radical acceleration, a series of grade-advancements which

results in the student graduating from high school three or more years earlier than is customary.

It is now generally recognized (Hollingworth, 1942; Cronbach, 1996; Benbow, 1998) that for highly gifted children some form of acceleration is essential if they are to find significant numbers of students of their own mental age with whom they can form healthy and productive social relationships. The findings, since the early 1970s, of the Study of Mathematically Precocious Youth provide powerful arguments for the intellectual and social benefits of academic acceleration for highly gifted youth (Benbow et al., 1996).

However, Hollingworth (1942) and Terman & Oden (1947) in their follow-up research on the young adults in Terman's gifted group, argued forcefully that for extremely gifted children the more conservative accelerative procedures such as a single grade-skip were not sufficient; they strongly advised radical acceleration through several grade-skips spaced appropriately through the student's school career. Gross (1992, 1993a, 1998b) found that for children of IQ 160+ a token grade-skip of one year, even when supplemented with in-class enrichment or pull-out, has been no more effective, academically or socially, than retention in the heterogeneous classroom. In the considerable majority of cases, children who have not been radically accelerated display low levels of motivation and social self-esteem, are more likely to report social rejection by their classmates, and are required to perform in school at levels several years below their tested achievement.

In striking contrast, 16 of Gross's 58 subjects of IQ 160+ have been radically accelerated; nine have already entered university, at ages between 11 and 16. All are experiencing high levels of academic success and have full social lives (Gross, 1998a). None regrets having taken such an accelerated pathway through school. As Roshni Singh, of IQ 162, comments; "I'm sorry it was necessary to do something that was so unusual at the time, but I certainly don't regret *doing* it. The alternative—staying with age-peers—would have been intolerable". Ian Baker of IQ 200 bleakly encapsulated his life in the heterogeneous classroom in a single word: "Hell" (Baker, 1991).

# Motivation and Cognition: Their Role in the Development of Giftedness

Willy Lens<sup>1</sup> and Per Rand<sup>2</sup>

## Introduction

When Thomas Edison said “Genius is 1% inspiration and 99% perspiration,” ‘genius’ referred to an outstanding level of performance (in whatever type of achievement tasks) and Edison wanted to stress that such high achievements or excellent performances depend much more on individual differences in perspiration, transpiration, effort or motivation than on individual differences in inspiration, abilities, capacities. He made a distinction between ability and level of performance, and he certainly underestimated the relative importance of abilities and he overestimated the role of motivation as determinants of exceptional achievements.

Merriam Webster’s Collegiate Dictionary (1993, 10th edition, p. 486) defines ‘genius’ as “extraordinary intellectual power especially as manifested in creative activity” and ‘gifted’ as “having great natural ability”. For Marland (1971) gifted and talented children are capable of high performance, by virtue of outstanding abilities; children capable of high performance include those with demonstrated achievement and/or potential ability. Giftedness then refers to exceptionally high levels of general intellectual ability, or of specific abilities or aptitudes. Passow’s (1985) brief review of the literature shows however quite clearly that there is no generally accepted common understanding of the nature of giftedness; it can refer to high abilities as well as to high achievement, or both.

“Can giftedness be considered as potential or must it be made visible through actual performance? . . . While giftedness has long been associated with high intelligence and high academic achievement, the dominant conceptions of giftedness which have emerged in many cultures focus on high order of potential or achievement in a variety of areas other than academic alone (o.c., p. 2048).

Terman (1925, p. 19) limited giftedness to exceptionally high levels of ability when he defined it as:

“... A degree of brightness that would rate them well within the top one per cent of the population”,

Brightness refers then to very high (above 135 or 140) IQ scores, or levels of performance on an intelligence test. It was “Terman’s hypothesis that early promise of intellectually gifted students is likely to culminate in relatively outstanding achievement during adulthood” (Passow, 1985, p. 2046).

Renzulli (1978) does not agree with Terman’s unifactorial definition of giftedness and developed his own three components model. In addition to high levels of general or specific abilities and high levels of motivation or task commitment, Renzulli adds creativity as a third component. For him giftedness is constituted by the interaction of those three personality characteristics:

“An interaction among three basic clusters of human traits—these clusters being above average general abilities, high levels of task commitment, and high levels of creativity. Gifted and talented children are those possessing or capable of developing this composite set of traits and applying them to any potentially valuable area of human performance” (Renzulli, 1978, p. 261).

Creativity refers to original and highly inventive ways of formulating and solving complex and difficult problems; creative people have high problem sensitivity, often concentrating their analyses on the novel aspects of the situation. They produce many and original ideas which they apply flexibly, using divergent rather than convergent thinking (Guilford, 1967).

It is interesting to notice already here (see also our next section) that Renzulli not only talks of ‘possessing’ but also of ‘capable of developing’ giftedness. For him, the three components are essential for giftedness and he refers to the common mistake made when identifying giftedness to exceptionally high intellectual abilities. That is because he also derives giftedness

<sup>1</sup> University of Leuven, Belgium.

<sup>2</sup> University of Oslo, Norway.

from creative, productive high achievements. For Mönks and his collaborators (Mönks & Span, 1984; Mönks & Knoers, 1994; Mönks & Ypenburg, 1996) these three components are not more than personality dispositions that must be stimulated and developed in a social context. The three most important social settings in which a child grows up and develops are the family, the school and the peers. The family can nurse and stimulate giftedness, but also suppress or hinder its development when it is not recognized as such. Schools that do not recognize the specific abilities and potentialities of gifted children de-motivate their development. Neglecting individual cognitive differences, focusing on the middle group and expecting an equal progress from all pupils has negative motivational and learning consequences, not only for the less able but also for the most intelligent pupils. Quite often, really gifted children are not accepted by their peers and this may also negatively affect their psychological development and their scholastic achievements.

It is clear that for Renzulli and for Mönks giftedness can refer to high abilities and/or to exceptionally high achievements; this conceptual confusion is very characteristic for the field. Renzulli's (1986) three-ring conceptualization and Mönks' triadic interdependency model of giftedness discuss mainly the determinants of high and creative achievements. But from the very beginning, an important part of the research on gifted children had to do with their underachievement or much too low school performances (Terman & Oden, 1947; Whitmore, 1980; Mooij, 1991; Butler-Por, 1993, 1995). When so-called 'gifted' children can be under-achieving, 'giftedness' does only refer to high levels of intellectual abilities and potentialities; conceptually it is then clearly distinguished from high achievements. When we discuss the role of motivational processes in the development of giftedness, we do make a distinction between exceptionally high levels of abilities as potentialities and high intellectual (academic) achievements. It should become clear however that the two are mutually interdependent. Unique accomplishments require high levels of abilities (potentialities) and important achievements foster the further development of those abilities, as we will discuss.

### **Level of Performance as a Function of Motivation and Ability**

As implied in Edison's dictum, a high achievement or level of performance depends not only on high ability but certainly also on motivational factors, be it probably much less than Edison argued. For Atkinson (1974) individual differences in intellectual abilities explain about 66% of the variance in academic achievement and motivation explains about 33% of the differences in school results. As expressed in Vroom's formula (1964, p. 203) and by many others before and after him, the level of performance in an achievement

task is indeed a multiplicative function of abilities and motivation:  $\text{Level of Performance} = f(\text{Ability} \times \text{Motivation})$ ; but how can we know someone's level of ability unless we measure it?

To start with we will discuss the distinction between true abilities or potentialities (e.g. general intelligence), measured abilities or test performances (e.g. IQ scores) and cumulative achievement (e.g. a scholastic or a professional career). We will discuss the role of motivational and other conative variables as determinants of the development of individual differences in the three of them.

People do indeed more often things that they like to do than things that they do not like and by doing so, they become better at it. That is a first explanation for a developing positive correlation between motivation and ability. In the next paragraph we will discuss a second explanation for that developing correlation. Indeed people also like to do things that they are good at; people become more motivated for tasks that they can do well. In that section we will also discuss the different categories or types of motivation that are usually distinguished in motivational research in general and in educational motivational research in particular. We will discuss the circumstances in which (exceptionally) high levels of ability will have facilitating and debilitating effects on those different types of motivation that are most relevant in an educational context.

### *Test Performances and Cumulative Achievements*

When analyzing the role of individual differences in ability and in motivation as determinants of the level of intellectual performances Atkinson (1974; Atkinson, Lens & O'Malley, 1978) made an important distinction between test performances or the level of performance while at work (e.g. an exam, an intelligence test, studying maths) and cumulative achievements that are built up over time (e.g. grade point average in a given academic year; the level of educational achievement). Motivation has a different role in these two types of tasks.

### *Motivation and Intellectual Test Performances: True Ability (the Ever Unknown) and Measured Ability (IQ Scores)*

The level of performance that is reached at each moment in time when working at a cognitive task or test is a function of: (a) the true knowledge and intellectual capacities or abilities, and (b) the efficiency with which the individual makes use of those cognitive abilities. The strength of motivation affects the quality of cognitive functioning at each moment in time because motivation determines how efficiently abilities are applied. The relationship between motivation and efficiency of cognitive functioning is, however, not necessarily linear, as assumed when blindly applying

linear statistics. It can be inverted U-shaped (Yerkes & Dodson, 1908; Atkinson, 1974, p. 198). Such a curvilinear relationship implies that the efficiency and the level of performance will increase when the motivation increases from low to medium or medium to high. But when the strength of motivation to perform well increases beyond an optimal level, the efficiency of cognitive functioning will decrease. The optimal level of motivation is that intensity of motivation at which the efficiency is 100% and the individual makes maximal use of his/her true abilities; lower as well as higher levels of motivation (lower or higher than the optimal level) cause inefficiency. The second part of the too often neglected Yerkes–Dodson Law holds that the optimal level of motivation depends on the difficulty of the task; the more difficult the task, the lower the optimal level, the higher the probability of being over-motivated.

“The more general guide provided by the old Yerkes–Dodson hypothesis is that the shape of the curve describing efficiency of performance in relation to strength of motivation will depend upon the nature of the task . . . A simple, overlearned task . . . may, perhaps, produce the monotonic increasing function we have traditionally assumed . . . A more complex activity . . . may produce the kind of curvilinear relationship . . . Still other tasks, perhaps those which require a very cautious, deliberate or relaxed approach, might produce a decreasing function for most of the range of motivation . . .” (Atkinson, 1974, p. 199).

Individual differences in strength of the achievement motivation affect the quality of cognitive functioning and hence the level of performance in intelligence tests/intellectual tasks. IQ scores or the level of performance in an intelligence test must be considered as the product of the individuals’ ‘true ability’ and the “efficiency with which they make use of their true ability during the test performance,” which may be curvilinearly related to the strength of motivation to perform well in the test (Atkinson, 1974; Nygard, 1977a, b; Lens & De Volder, 1980). Taking into account existing individual differences in achievement motive, test anxiety, perceived task difficulty, there is no reason to assume that a given standardized test situation arouses the achievement motivation to an optimal level for all subjects. Individuals who are more or less strongly motivated than the optimal level while taking the intelligence test, will have their true intelligence underestimated by their IQ scores; they are underachieving on the test. Not only low levels of motivation, but also a very high level of motivation to perform well on the test will interfere with efficient test behavior. For Atkinson (1974, p. 395):

“It is essential to emphasize that the mental test movement for many years has implicitly made the claim, without adequate justification and certainly in the absence of knowledge, that the level of motivation is either optimal for everyone being tested, or constant, or only negligibly different among all individuals at the time of performance. . . . Until proven otherwise, any measured difference in what has been called general intelligence, scholastic aptitude, verbal or mathematical ability, . . . which is always obtained from performance under achievement-oriented if not multi-incentive conditions, can be given a motivational interpretation with no less scientific justification than the traditional aptitudinal interpretation.”

Interpreting individual differences in IQ scores as reflecting individual differences in intellectual ability as well as in motivation, implies that lower IQ scores do not always reflect lower intellectual ability. Highly gifted youngsters who are totally uninterested in their test performances or who are much too strongly motivated or aroused when taking the test will perform much below their true ability. They will not (immediately) be recognized as highly talented; it also implies that the true ability is the ever unknown.

### **Motivation and Cumulative Achievement**

The level of cumulative achievement reached over time depends on the level of performance while at work and on the amount of time spent at the cumulative task (Atkinson, 1974); motivation affects both components. We discussed above the relationship between strength of motivation and the level (efficiency) of performance at each moment in time or while at work. In addition, people will spend more time on intellectual tasks the more they are motivated to excel in such tasks and the less numerous and strong are the competing behavioral tendencies. Atkinson and Lens (1980) distinguished two effects of spending more time in a particular endeavor; first, the cumulative achievement or the level of performance that is realized over shorter or longer time spans. The more years one spends in the school system, the higher will be the degree (e.g. high school degree, a college degree, a degree from graduate school); but as the proverb says, ‘Practice makes perfect’. Spending more time (practicing more) will also have an effect on the individual; it results in a growth in knowledge, abilities, capacities. This explains why a positive correlation should develop between motivation and abilities: the more motivated for or interested in a particular domain (e.g. mathematics, a foreign language) the more time one will spend in that domain and the more one will develop those capacities, abilities, the better one becomes. Highly motivated students will study more and by

doing so they will not only obtain better school results but also become more able, more intelligent. Kagan and Moss (1962) concluded their developmental study of intelligence as follows:

“For certain populations the IQ can serve as an index of achievement concerns . . . when one is working with children whose IQ scores are average or above, level of intelligence and increases in test scores appear to be good indexes of the strength of overt achievement behavior during childhood, adolescence and adulthood, and a reflection of intensity of motivation to master intellectual tasks ‘ (o.c., pp. 151, 152).

Which intellectual abilities one prefers to develop and to what degree one wants to do so, depends on motivational variables; see for example Anastasi (1982, p. 352): “Even more important is the cumulative effect of personality characteristics on the direction and extent of the individual’s intellectual development.”

Behavior (B) does not only result from an interaction between personality characteristics (P) and perceived environmental variables (E), as implied by Lewin’s famous formula  $B=f(P, E)$ . Quite often, doing something for a while affects the individual (for example, studying changes the content and the structure of the long term memory store) and it may have effects on the environment (e.g. operant behavior). There is a second process that can explain why a positive correlation between motivation and intellectual abilities will develop. In the foregoing we explained how individual differences in motivation or interest may affect the development of individual differences in (intellectual) abilities. A not too extremely high level of motivation for intellectual tasks and only very few competing side interests ensures a maximum free time to be devoted to intellectual development. (We do not want to say here that this is most optimal for the development of a rich personality). The causal influence can however also work in the opposite direction. Due to largely genetically determined individual differences in intelligence or other abilities, some children achieve more often and more important successes in tasks invoking those intellectual or other types of abilities. The intrinsic satisfaction of successfully applying one’s competencies enhances the intrinsic motivation for such tasks; people are, or become, motivated to do things that they are good at. For Deci and Ryan (1985) the perception of competence (in circumstances of self-determination) creates intrinsic motivation; people are motivated to be competent and efficient in their interactions with the world. We refer here to White’s concept of “competence motivation” (White, 1959) and Bandura’s concept of ‘self-efficacy’ (Bandura, 1986, 1997).

### *A Motivational Explanation of Underachievement*

Underachievement is a quite common problem among gifted children (Whitmore, 1980). Terman and Oden (1947) found in one of their follow-up studies that a rather high number of highly gifted subjects perform below what might be expected based on their intellectual potentialities. Butler-Por (1993, 1995) defines underachievement as a growing discrepancy between the high ability (as observed by teachers and parents or as expressed in measures of intelligence or creativity) and the much too low school results. Notice the important difference between underachievers and low achievers. Underachievers are performing in a criterion measure, such as grades in school, much lower than was predicted based on scores in a predictor measure such as a general intelligence test. This implies that highly gifted children who score in the middle or even the top of their class may be underachieving. They could do better, given their true ability. Taking into account that giftedness can be limited to a particular ability (e.g. mathematics, languages), pupils’ relatively high scores in maths or languages can nevertheless be an underachievement, while their lower grades for other courses are not.

Whitmore (1980), Span (1988), Butler-Por (1993, 1995), Piirto (1994) and many other authors distinguish different types of underachieving gifted children and they refer to many explaining factors that can be situated in the children, in their home environment and at school. Several of these debilitating factors affect the level of performance and hence cause underachievement because they undermine the children’s daily motivation for school work. Atkinson (1974) formulated the following motivational explanation for underachievement in general, but that can also explain underachievement among high ability pupils. At the moment that their abilities (e.g. general intelligence) were measured, they were optimally motivated and made maximal use of their true abilities. Their (very) high score on the test expresses their true high abilities or potentialities. However, for regular schoolwork they are less than optimally motivated and they perform way below their actual potentialities. Due to motivational problems, they perform lower than could be expected on the basis of their test scores and they do not develop their potentialities; their intellectual development levels off. They do not become ‘perfect’ because they do not ‘practice’ enough. Really bright young children end up as regular students (or even worse). Lack of motivation hinders both high achievement and becoming a real ‘genius’. In the next section we will discuss how different types of motivation can be undermined at school and at home.

It is very easy and quite common to perform below one’s abilities or to be an underachiever; it is of course impossible to be an overachiever if that means to

perform better than one's abilities would allow. Overachievers are performing better than one would predict or expect on the basis of a predictor-measure, for example test scores. For Atkinson (1974) they are underachieving in the predictor measure; because they are not enough or too much motivated to do well on the test, (below or above the optimal level of motivation) they are not 100% efficient and their test scores underestimate their true abilities.

### Motivational Effects of Individual Differences in Abilities

Different from the neo-behavioristic Hullian approach in psychology, we do not have any longer one global theory of motivation that is supposed to explain all aspects of motivated behavior. Basic and applied research has resulted in a number of more limited mini-theories, discussing and explaining some aspect(s) or component(s) of the total motivation instigating and/or sustaining behavior.

Theories of human motivation can be classified in two broad categories: content theories and process theories. Content theories reduce motivation to more or less stable, inborn or acquired instincts, drives, needs or motives (e.g. the motive to succeed or the need for achievement). Process theories consider motivation as a psychological process in which personality characteristics (e.g. motives, needs, abilities, expectancies) interact with perceived characteristics of the environment (e.g. content and difficulty of learning tasks, teachers, parents and peers). Lewin's conceptualization of behavior as resulting from the interaction between the individual and the perceived environment [ $B=f(P, E)$ ] is extended to also cover motivational processes. For example, the strength of the achievement motivation is not only affected by the individual strength of the achievement motive, but also by the difficulty of the achievement task. Process theories imply that characteristics of both the individual and his or her behavioral situation should be taken into consideration when trying to understand, explain and influence motivation (Snow, 1989; Snow & Swanson, 1992).

Content theories attribute the motivational cause(s) of behavior (a movement) solely to the behaving individual (the moving object), and not to the environment in which the movement takes place (the behavioral situation). Process theories attribute the movement of an object to characteristics of that object and of the environment in which the movement takes place. The difference between Renzulli's and Mönks' definition of giftedness (see above) is very analogous to the difference between content theories and process theories.

In the following section we will discuss several process-theories of motivation that are relevant for understanding the role of motivation in the development of giftedness and in high levels of performance.

We will do this for intellectual giftedness and for academic performances; but it will become clear that the discussed models apply for other types of abilities and in other domains of achievement as well.

### *Intrinsic and Extrinsic Motivation*

It holds for most of our behaviors that they are at the same time intrinsically and extrinsically motivated; actions are extrinsically motivated when they are done for the sake of rewards or other consequences that are not intrinsically related to the activity. The activity is instrumental and its motivation can be called 'instrumental motivation'; an activity is intrinsically motivated when it is done for its own sake, when it is a goal in itself. Although it is certainly true that learning and working can be both intrinsically and extrinsically motivated, it is quite striking to notice that research on work motivation traditionally concentrates on extrinsic motivation and that research on the role of motivation in education usually discusses different types of intrinsic motivation.

For many years it was assumed that student motivation, as well as work motivation, is the sum of intrinsic and extrinsic motivational components; each intrinsic and extrinsic goal can be conceived of as an additional source of motivation. At each moment in time, the total motivation can be increased by increasing either the intrinsic motivation or the extrinsic, or both; motivational problems at school are usually due to low levels of intrinsic motivation (Lens & Decruynaere, 1991). Parents and teachers try to compensate insufficient (intrinsic) motivation by offering extrinsic rewards in order to increase the extrinsic motivation, and hence also the total motivation. As we will explain later, nothing is wrong with this practice, if the intrinsic motivation is missing or very low.

The additive model does however not hold when we look at dynamic interactions between intrinsic and extrinsic motivation; basic experimental research over the last twenty years shows that intrinsic and extrinsic motivation are not necessarily additive. Salient, promised extrinsic rewards that are exogenous to the nature of the task, and that are given for already intrinsically motivated activities, may undermine the intrinsic motivation (Deci, 1975; Lepper & Greene, 1978; Luyten & Lens, 1981; Deci & Ryan, 1985, 1992). They do so when they produce an over-justification effect; the individual sees too many reasons for doing the task: the already present intrinsic interest and the promised extrinsic reward. Due to the fact that rewards are usually more salient, they are progressively seen as the reason for doing the task and the intrinsic interest dies out. The rewards and other external controlling measures cause a shift in the locus of causality from internal to external. Intrinsically motivated individuals see their own interest in the subject matter or the task as their

sole reason for doing it. When they then repeatedly receive extrinsic rewards, those rewards become the external reasons for learning and performing well. Not the intrinsic interest, but the extrinsic rewards are from then on controlling those activities; the intrinsic interest disappears. Not only announced rewards but also evaluation, surveillance, coercion, time pressure may cause such a change in the locus of causality from internal to external and undermine the intrinsic motivation.

The low level of intrinsic motivation among many high school pupils may be partly due to this undermining effect of the many extrinsic rewards they received in elementary and (junior) high school for doing their best at school and for high marks. Harter (1981) found "... a systematic, grade-related, shift from a predominantly intrinsic motivational orientation in third grade to a more extrinsic motivational orientation by ninth grade, the biggest shift occurred between the sixth grade elementary school students and the seventh grade junior high school students" (Harter & Jackson, 1992, pp. 223–224). This is even more so for gifted children who—at a young age—are usually very highly motivated to learn and develop their exceptional abilities (Gottfried, 1990; Gottfried et al., 1994). As we will explain in the next section, they are even more vulnerable to situational circumstances undermining their (different types of) intrinsic motivation.

More recent meta-analytic research shows however that "... detrimental effects of reward occur under highly restricted, easily avoidable conditions ..." (Eisenberger & Cameron, 1996, p. 1153). Extrinsic rewards do not have this negative effect on intrinsic motivation when they are given in such a way that their controlling aspect is much less salient than their informative aspect; they can be given in such a way that they tell students how good they are at the tasks for which the rewards are given. They then strengthen perceptions and feelings of competence, enhancing the intrinsic motivation (Deci & Ryan 1985). Extrinsic rewards "... can sometimes complement or increase intrinsic motivation ..." (Rigby, Deci, Patrick & Ryan, 1992, p. 168). The intrinsic motivation will not be undermined when people can stay "self determined even when offered extrinsic motivators" (o.c., p. 168).

Extrinsic rewards and other sources of extrinsic motivation may even instigate an intrinsic motivation. Activities such as studying, plumbing, jogging may originally be motivated only by extrinsic goals such as rewards, making a living, staying in good health; after a while the same activities may become intrinsically interesting for an individual. For example, an unmotivated pupil who hates maths tries to solve additional mathematical problems as homework because the teacher or parents promised a reward for doing it. If the problems are not too easy, nor too difficult, and when their content is related to the child's life (contextual or situated topics) that pupil may then find out that she is

good at it, that it is fun to find a solution for a challenging problem. Her feelings of competence will be strengthened and an intrinsic interest in mathematics may develop. Although this phenomenon has been well known in motivational psychology for many years, it is often neglected in the discussion on the interaction of intrinsic and extrinsic motivation. Allport (1961) calls it "the functional autonomy of motives." Actions that used to be instrumentally or extrinsically motivated become functionally autonomous and intrinsically motivated. Woodworth (1918) referred to this process as "mechanisms become drives."

### *Intrinsic motivation*

Motivation in general and intrinsic motivation in particular, are important determinants of creativity, of high achievement and the development of high abilities. Renzulli, Mönks and many others consider a strong motivation, task-commitment and perseverance as basic components of giftedness. High abilities are necessary but not sufficient for outstanding achievement or for the development of genius. This implies that motivational problems can be an important cause of underachievement and less than optimal development of potentialities. We will now discuss several types of intrinsic motivation and why highly talented children may have problems with those different types of motivational orientation.

### *Curiosity*

Intellectual or epistemic curiosity is probably the most typical type of intrinsic motivation for learning; the desire to know and to understand intellectual problems is aroused by moderately discrepant, complex and novel information. Familiar or simple information arouses only indifference, satiation and boredom, while information that is too complex or totally new may cause anxiety and/or withdrawal. This need for information and knowledge is very strong among young children, but seems to decrease and even disappear during the high school years; our schools do not seem to appeal to this intrinsic need (Bruner, 1966). The type of intellectual problems, information and knowledge that is offered in formal education in schools is for many children too much decontextualized to arouse their curiosity.

Developmentally, creativity presupposes on the motivational side in particular curiosity, often also a will to 'do it myself'. The favorable environment for both the development of creativity and curiosity in children is one where there is time, room and encouragement for the child's self-initiated exploratory behavior (Trudewind, 1975, p. 153–154).

Most high IQ-children with a typically high curiosity start to read, write and calculate at a much younger age than less gifted children do and they learn at a much faster rate; in intellectually heterogeneous classes, the

program and its pace easily bore them. Some of them compensate their intellectual frustration in school by developing a special intellectual interest (e.g. computer programming, space exploration, and wars); but that will not greatly help their motivation at school.

#### *Need for Competence and Efficacy*

The need for mastery, competence and efficiency in solving challenging tasks is a second type of intrinsic motivation that is highly relevant for schoolwork in general and for very able pupils in particular. For Malone and Lepper (1987), curiosity is the need of humans as information processors and the need for mastery characterizes humans as problem solvers. Perceptions of competence and self-efficacy (e.g. "I am good at it; I can do it") are intrinsically motivating (Deci, 1975; Deci & Ryan, 1985). As mentioned earlier, people like to do things that they are good at and they also become good at things that they like to do; students are motivated and invest considerable effort when they can expect to master a challenging task. In addition Locke and Latham (1990) stress in their goal-setting theory of task motivation that people will be more strongly motivated and perform better when the tasks are difficult but attainable.

Perceptions of competence and efficacy require challenging tasks; tasks that are too easy or too difficult are not challenging, hence not motivating; in such tasks, one cannot expect to feel competent and efficient. Success in easy tasks is highly probable but it will not be attributed to abilities or competence, but to the low degree of task difficulty; it will not enhance the perception of competence and self-efficacy. Failure in an easy task is very informative about the (low) level of ability, but it is of course highly unlikely, certainly for gifted children. When the task is very difficult, success would give much information about high competence, but success in such tasks is highly unlikely. Success experiences stimulate academic self-concept and self-efficacy only when they can be internally attributed to abilities and/or effort.

We can expect that, in general, gifted children will score highly for perceived competence and academic self-efficacy (Wagner, Neber & Heller, 1995). Social comparison teaches them that they are much more gifted than their peers and that they have much less difficulties in understanding and solving school related problems; these are two important determinants of self-efficacy (Bandura, 1986).

However, we see several reasons why truly gifted children do not develop the motivating conceptions of high ability and high self-efficacy. First, the intellectual tasks they are confronted with in school are usually too easy and too simple and hence not challenging at all for them; in general, teaching is adapted to the middle slice of students. The learning and achievement tasks are then too easy for the able students and too difficult for the lowest third in the class to be motivating. Second,

for Mönks and Ypenburg (1995), perfectionism is a rather common trait among gifted children. Piirto (1994) distinguishes enabling and disabling perfectionism. Many gifted children strive for perfectionism; they set high standards of excellence and they are very critical for themselves; they are not easily satisfied with the quality of their work. When those high standards of excellence are highly motivating and facilitate high achievement, what they often do (Whitmore, 1980), it is an enabling perfectionism. However, perfectionism can also lead to unrealistic goals that cannot be achieved or realized, because they are too difficult or too complex. Perfectionism is then debilitating (disabling perfectionism), it creates anxiety, stress and psychosomatic symptoms; about 15 to 20% of gifted people will now and then suffer from their perfectionism. Studying perfectionism among gifted children, Parker (1997) found three types: the non-perfectionists (32.8%), the healthy-perfectionists (41.7%) and the dysfunctional perfectionists (25.5%). The latter group scores higher than the two others on perfectionism and neuroticism; they are also very competitive and perceive their parents as very demanding and very critical; this is a third reason why gifted children may not develop a motivating degree of self-efficacy. A stimulating and scaffolding social environment is an important prerequisite for giftedness and creativity (Mönks & Ypenburg, 1995), but when teachers and parents expect too much too soon, the children may develop lack of confidence, fear of failure, anxiety and stress; they will underachieve, certainly in terms of the unrealistically high expectations.

#### *Achievement motivation*

The need for mastery and efficacy is closely related to the achievement motive or the need for achievement. The strength of the resultant achievement motivation is the algebraic sum of two components: the positive tendency or motivation to strive for success and the negative tendency or motivation to avoid failure. The positive tendency is a multiplicative function of three factors: (a) the motive to succeed, (b) the subjective probability of success or the expected difficulty of the achievement task, and (c) the anticipated positive incentive value of success (the harder the task, the higher the incentive value of success). Analogously, the negative tendency to avoid failure is a multiplicative function of (a) the motive to avoid failure, (b) the subjective probability of failure, and (c) the anticipated negative incentive value of failure (the easier the task, the stronger the shame for failing) (Atkinson, 1964).

For success-oriented individuals, the resultant achievement motivation is a positive approach tendency and for failure-threatened or test-anxious individuals it is a negative, inhibitory tendency not to approach achievement tasks. Achievement tasks that are either too easy or too difficult do not arouse the achievement motivation; for the most gifted children in

an intellectually heterogeneous class, the tasks will be too easy to be motivating and when competing with others they have a high probability of success; but an easy success has not much incentive value. Given that gifted children usually score low on test anxiety or fear of failure (Butler & Nissan, 1975; Milgram & Milgram, 1976; Gottfried et al., 1994) it can be expected that they will be more strongly motivated for success in homogeneous classes with more difficult tasks and more competition. Atkinson and O'Connor (1963) did indeed find that success-oriented pupils are more motivated in homogeneous classes.

Another important factor to be taken into account when determining the strength of a person's achievement motivation is future time perspective (Gjesme, 1996). For Atkinson and Raynor (1974, p. 5) future time perspective or future orientation is "... the impact on motivation for some present activity of perceiving its instrumental relationship, as a step in a longer path, to more distant future goals and threatening consequences" (Atkinson & Raynor, 1974, p. 5).

A person who has a long future time perspective will, compared to a person with a short future time perspective, 'see' further ahead, and include more distant future happenings in his/her plans. A person with a long time perspective will perceive a future goal closer than a person with a shorter time perspective does (Lens, 1986). The motivation for working towards a goal will be more strongly aroused the closer the person perceives the goal; chronological time distance is of course also an important factor influencing the perceived goal distance in time.

Gjesme found that "... the arousal of motives increases as the subjectively experienced goal distance in time decreases" (Gjesme, 1981, p. 124).

For Gjesme (1996) and Zaleski (1987) the influence of the future goal on the present motivation to work towards that goal depends partly on the importance of the final goal, the perceived instrumentality of present actions for reaching that goal, the distance in physical time and the individual future orientation.

Length or extension of future time perspective correlates positively with general intelligence (Nuttin et al., 1979). This means that highly intelligent children at a younger age can easily foresee the distant future and take it into account in the present. They perceive more easily the instrumental value or utility of their present actions and that will increase their motivation.

In summary, the three types of intrinsic motivation that we discussed above, are all very relevant in building cognitive structures and content, and play an important part in the development of giftedness. The creativity part (cf. Renzulli, 1978) is for its early development motivationally dependent on curiosity, and often also on a will to 'do it myself'; later in life intrinsic motivation may not play the same dominant part. Extrinsic motivation increases in importance, but must not be seen as the big bad wolf (Harter &

Jackson, 1992; Heyman & Dweck, 1992; Lens & Rand, 1997; Husman & Lens, 1999). One cannot assume that the moment a goal outside the ongoing activity enters the picture, all is ruined; one must accept performance goals. It is not possible only to pursue interesting things, and abstain from meeting the performance demands needed for entering or continuing studies, and thus spoiling the chances of reaching own long-term goals.

Dweck (1986) differentiates between three types of achievement goals as: (a) the wish to develop competence, (b) to reach competence, and (c) to demonstrate competence. According to Pintrich and Schunk (1996) Dweck's two first types of goals may be called learning or mastery goals (intrinsic ones), while the third is a performance (with extrinsic motivation).

An optimal level of motivation is usually connected with a high learning goal orientation, and low performance orientation. However, lately several authors report positive effects of performance goals on cognitive engagement, well adapted learning strategies and on academic performance (cf. Bouffard, Boisvert, Vezeau & Laroviche, 1995; Wolters, Yu & Pintrich, 1996; Skaalvik, 1997). To strive for performance goals through competition with others does not exclude working towards learning goals; simultaneous striving for both is possible, if there is a certain basis of learning goals. Wentzel (1991) actually found that pupils who strive towards both types of goals show a higher degree of self-regulation and higher performance than pupils who only work towards one type of goal. The authors who share this view often stress that the double goals are usually found in pupils/students on the higher steps of education (college and university students), who have chosen their courses themselves so that they are related to their future work career. At this level there may be a real need for competition, because further study in the wished-for direction may be restricted to the best part of the student group.

### Conclusion

The close relationship between cognitive and motivational development might be explained in two ways. Differences in motivation may create differences in cognition, reflected in intelligence test scores and in cumulative intellectual achievements over time. Highly motivated individuals would always seek out a variety of challenging task situations; they work hard and they are persistent. As a consequence, they might accordingly develop higher ability to tackle new situations. But differences in cognitive ability/intelligence may also create differences in strength of motivation; a child with high abilities and a nurturing learning environment will have many opportunities to experience goal attainment, success and intellectual satisfaction. Those positive affects are the basis for the development of the several types of intrinsic and extrinsic (instrumental) motivation.

# Social-Emotional Development and the Personal Experience of Giftedness

Laurence J. Coleman<sup>1</sup> and Tracy L. Cross<sup>2</sup>

## Introduction

Social-emotional development is particularly important because it is clear that non-intellective factors are crucial to understanding the emergence of giftedness (Tannenbaum, 1983). The literature on social-emotional development of children who are gifted and talented is broad with much written on it, much expressed clinically about it, and scattered systematic study about it. Most of the literature is written from the perspective of detached scholars as well as staunch advocates for programs designed on behalf of the gifted. The result is a mass of interesting, sometimes contradictory, information and a fertile ground for all kinds of entrepreneurial activity as witnessed by the parent-help books and workshop training opportunities for teachers.

The purpose of this chapter is to provide a means for understanding the social-emotional development of gifted students. In this chapter we introduce a structure for understanding the topic that looks at giftedness and talent from the inside, attempt to clarify some of the issues and suggest how we might expand our knowledge base. We start with clarifying statements and assumptions about our topic, continue with some discussion of major questions that govern the topic of social-emotional development, and encourage two approaches to the study of experience as means of expanding our understanding of the topic. More specifically, issues such as nature/nurture concerns, universal and nonuniversal patterns of development, endogenous and exogenous characteristics of gifted students and culturally-based issues of giftedness are discussed. From all this, a means of considering the social-emotional development of gifted students is articulated that includes several components: social cognition, stigma management, and lived experience. The discussion uses experiences in school to illustrate

meaningful interactions that affect the long term social-emotional development of gifted students.

## Clarifying Statements and Assumptions

There are several important assumptions held by the authors that underpin the ideas proposed in this chapter. While many in the field of gifted education have focused on the social and emotional needs of gifted students, we assume more of a developmental approach. We prefer the term social-emotional development over the term emotional development because it makes it clear that emotional development occurs in a social matrix. Talking about development as if those influences do not exist makes little sense to us. We also contend that the separation of emotions from cognition is false. When we use the term social-emotional, we are always assuming the influence of thought. Therefore, gifted students are assumed to be active agents in their social-emotional development. For example, just as social forces influence development, the emotional content of symbols and actions as interpreted by the individual influence development. We rarely use the term personality in the discussion because it seems to be an even broader construct than social-emotional development. Lastly, our presentation wavers back and forth between normative issues that apply to all those who are gifted and unique personal issues that refer to individual development. In general our discussion begins with a normative discussion and moves toward the unique.

## *Terms Used in the Social-Emotional Realm: Needs, Characteristics and Issues*

Researchers have claimed that the social-emotional needs of gifted students are a byproduct of one of two possibilities. The first possibility is that needs will exist as a function of specific individual characteristics (endogenous) the gifted student possesses. For example, excessive perfectionism is a personality characteristic that can influence a child's experience of the world in a certain way. Consequently, in this child's experience, this personality characteristic

reflects needs he or she has. The second way social-emotional needs can emerge is as a function of the child interacting within a specific environment. This interaction of characteristics with the environment yields exogenous needs. For example, a child who is self-critical and who exists in a school environment that encourages competition might experience a greater sense of self-doubt or poor self-image due to the struggle that is associated with that personal characteristic as it interacts with that setting. In other settings, however, the characteristic may elicit no social-emotional need per se.

Issues are examples of large, more general concerns gifted students have in school, or that affect the context in which the child exists in school. For example, a common issue for gifted students is working as peers with other students who are not as passionate about their schooling as they are. This issue exists in many school settings, but the prevailing attitudes of teachers and administrators vary based on their beliefs and the values held about giftedness, the role of schooling etc. For example, many principals believe that all children are gifted, while many teachers believe that students should accommodate the curriculum rather than the other way around. Perhaps the most commonly held belief by these two groups is that the whole concept of giftedness is elitist, and therefore something to be discouraged. Consequently, even though issues always surround gifted students while they are in school, their experiences are lived with myriad other influences or factors that affect their social-emotional development.

### *Needs of All Children*

It is generally assumed that all children have the same basic needs. Maslow's (1970) hierarchical theory provides a framework from which we can interpret the role of the needs. The theory asserts that people have several basic needs that must be satisfied before they can ascend to the higher tier needs. In the hierarchy, just after the first (physiological) and second needs (safety) are two needs relevant to the psychological and social domain – the need for belonging and love (level three) and esteem needs (level four). According to the theory, gifted children would have to have satisfied these two needs in the psychological and social realm before they would be able to move toward self-actualization (level five). The satisfying of needs consumes time and energy. In a very practical sense, the more time one spends trying to satisfy the lower level needs on Maslow's Hierarchy, the less time and energy can be spent operating at the higher levels that are generally more closely associated with being a successful student. An important conclusion from this theory applied to the development of the social-emotional needs of gifted students is that some of the influences on the development of gifted students are the same as those for nongifted students. While we

point this out, we do not conclude, however, that the influences are the same in either the experience of or effects on gifted and talented students.

### *Endogenous Characteristics of Gifted Students*

Researchers have been exploring the efficacy of Dabrowski's (1967) theory of personality as a means for understanding gifted students (Silverman, 1993; Mendaglio, 1995; Cross, Cook & Dixon, 1996). Piechowski (1986, 1997) has been the leader in forwarding the basic tenets of the theory that has two components: overexcitabilities and levels of development. In his theory, Dabrowski posited that gifted individuals manifest super-sensitivity (translated into English as overexcitabilities) in several areas: psychomotor, intellectual, sensual, imaginal and emotional. Overexcitabilities are described as expanded awareness, intensified emotions, and increased levels of intellectual and/or physical activity. The research in this area shows early promise in greatly expanding the understanding we have about gifted students in the social-emotional realm. For example, it should not be surprising to see a young gifted child being very upset by social injustices around the world. The level of emotional intensity might appear more common to an adolescent than a child of elementary age. Understanding that these strong reactions are an aspect of their gifted personality rather than a behavioral or emotional disorder has implications for teachers, counselors and parents (Mendaglio, 1995).

A common topic appearing in the research lore that considers the endogenous social-emotional characteristics and needs of gifted students is that they experience uneven development; sometimes called asynchronous development (Delisle, 1992; Silverman, 1993). This can be seen in differences between the level of their general aptitude, or specific aptitude, and other aspects of their development such as their physical abilities, or social and emotional development. Many in the field believe that asynchronous development represents a need in and of itself, regardless of the student's environment.

A second often mentioned social-emotional need described in the literature emerges from some gifted children's tendency toward perfectionism (Webb, Meckstroth & Tolan, 1982). Perfectionism is being dissatisfied with the difference between one's ideal performance and one's perception of his or her actual performance. This characteristic is also described as having unreasonably high expectations for one's performance. Numerous manifestations of problems have been attributed to perfectionism, such as high levels of stress, uncompleted projects and an unwillingness to engage in healthy risk-taking behaviors (Baker, 1996).

Another frequently discussed endogenous need of gifted children results from their tendency for excessive self-criticism (Anderholt-Elliott, 1987). This need

emerges from their pattern of being highly critical of themselves when they fall short of accomplishing an ideal performance. Since they may also have perfectionistic tendencies, their self-assessment will often be very disappointing, yielding excessive self-criticism.

Lastly, an often-discussed characteristic of gifted students is called multipotentiality (Silverman, 1993). Multipotentiality describes the way in which many gifted students show great promise and interest in numerous areas. Being successful in numerous areas is very difficult, and requires vast amounts of time and commitment to each area. According to some, multipotentiality often becomes problematic in the social-emotional lives of the gifted students because it can lead to higher levels of stress and emotional upset.

### *Exogenous Needs of Gifted Students*

As noted previously, exogenous needs emerge from the characteristics of the person within the culture, norms and expectations of a specific environment; they are not extant characteristics of the individual per se. In this chapter, the discussion is limited to the social-emotional needs of gifted students in a school environment. Before discussing their need, one should note that all the previous endogenous characteristics and subsequent needs may exist within the school setting. Because each school has its own personality and distinct social milieu, it is difficult to accurately predict the extent to which a particular gifted student will thrive or struggle due to his or her social-emotional make-up (Cross, Coleman & Terhaar-Yonkers, 1991). It is, however, reasonable to illustrate commonalities to gifted students' experiences and how they evolve over time. Perhaps the most common example of a gifted child's characteristics leading to social-emotional needs emerges from their desire for academic engagement while interacting within a school environment that is not accepting of students who are very serious about learning (Cross, Coleman & Stewart, 1995). This interaction can yield any of the following needs in the social emotional realm: a need to feel accepted, a need to affiliate with other gifted students, and a need for recognition of accomplishments. In short, studies have shown that exogenous needs emerge from the characteristics the gifted child has in either their psychological or intellectual domains interacting in an environment that is perceived and/or experienced by the child as being at odds with their social-emotional nature (Cross, Coleman & Terhaar-Yonkers, 1991; Cross & Stewart, 1995; Cross, Coleman & Stewart, 1995). Therefore, the same qualities the individual gifted student has in a different environment may not manifest in social-emotional needs. To gain insight into their social-emotional development, one should consider larger issues of the relative influences of nature and nurture of gifted students.

### **Considering the Role of Nature and Nurture in Social-emotional Development**

What governs social-emotional development? Is it nature or nurture? Is it universal or nonuniversal? Both questions seem to be foundational to the topic of social-emotional development. The first question looks at the biological-environmental bases of development; the second, at the everyperson-specialperson idea of development. Neither pole has unequivocal support; yet, the way in which the questions are answered by people influence interpretations about the topic of social-emotional development of the gifted.

#### *Nature-Nurture*

The question of nature and nurture is unanswerable, or only partially answerable, for many reasons. The most obvious is because the person we see is always a phenotype, never a genotype. Typical development is a consequence of multiple genes (polygenic), not a single gene, interacting in a changeable environment of some kind. Any person we meet is a product of interactions between genes expressed in the form of DNA messages and environments in the form of various social settings in the world. Thus, it may sound strange, yet it would be more accurate to use the adjective phenotypic before the word gifted or talented.

Acknowledging complexity does not mean that we cannot say something more definite about the relationship between nature and nurture. Research into the heritability of IQ indicates that about 50% or so of the score is attributable to genes and the rest to environment and to chance. It seems that, for IQ, nature may have the strongest influence among the three. However, two caveats are important to avoid an over interpretation of the statement's meaning. The first is that estimates of heritability refer to groups and not to individuals. The second caveat is that the statement refers specifically to general cognitive functioning and, most importantly for our topic, not directly to social-emotional development. There is no reason to assume that inherited factors are more or less important in social-emotional development than they are in cognitive development. In other words, the forces influencing development are nature and nurture, but how these forces play out for the individual is not knowable. This fact becomes most obvious when considering those persons who are the most gifted.

Commenting on the evidence on general intelligence and genetics, Plomin & Petrill (1997) offered a summary that applies to our discussion of social-emotional development. We recommend (recognizing the danger of this suggestion) that the reader substitute the term social-emotional development for the word intelligence in order to get a sense of the essential meaning of the nature-nurture discussion. It is important to emphasize what these findings do not imply. They do not imply that intelligence is predetermined.

The fact (sic) that intelligence is heritable does not mean that the genetic part of intelligence is non-malleable. It is also true that intelligence is often confused with a genetic predisposition to learn. Intelligence is a phenotype with about half of the variance of IQ scores having a nongenetic origin. Going further, because 50% heritability is an average estimate in the population, the importance of environmental factors may be greater for a particular individual's intelligence (p.73).

In recent years an idea – the niche-picking hypothesis – has emerged that speculates on the influence an individual's genetic make-up might have on his or her own development (Scarr, 1992). If the niche-picking hypothesis is valid, then persons may gravitate toward environments that fit their biological predisposition. This hypothesis is interesting because it suggests that unconscious forces have a role in a person's development by pushing a preference to be in settings that promote development. Thus, people are not simply passive beings waiting for their biological destiny to be played out, but active, yet oblivious seekers. While this idea is intriguing, our intent is not to endorse it but rather to underscore that nature-nurture interaction is dynamic. We are not suggesting that individual development is simply a matter of making choices among the social and natural forces that potentially influence development. One only has to imagine what it is like growing up in warring societies such as in the former Yugoslavia or in Rwanda to recognize that many forces are outside a person's control. However, the notion of finding oneself or placing oneself in the best environment for development reemerges later in our discussion of universal and unique development.

#### *Universal-nonuniversal*

The issue of universal-nonuniversal refers to the question of whether the social-emotional development of persons who are gifted and talented is the same as or different in some fundamental way from that of persons who are not gifted. This issue is related to the issue of whether gifted persons are qualitatively versus quantitatively different from the non-gifted. (Coleman & Cross, 2001).

In speaking of the development of giftedness, much is taken for granted about the topic. The conventional wisdom on the development of giftedness asserts that gifted children are children first and gifted second. Many in the field, including our own graduate students, often translate such assertions into the idea that gifted children develop like all children, an idea that might be inaccurate. We take the statement to be an announcement of value – that all children are valuable as persons first, and as gifted persons second – not as a statement of social-emotional development. We ask, is it possible that gifted children could develop in a manner that is different from that of non-gifted children? We know

that some persons accomplish or create in a way that seems to be unlike others. Does this mean that their developmental pattern is uniquely different from other children who are not gifted? Note that our questions do not ask whether the development of any individual is unique because we assume that always to be the case; no two individuals develop in precisely the same way. So, unique in this sense refers to the classes of persons who might be considered gifted in some manner.

Answers to the questions of universal/non-universal development fall within the field into three co-existing viewpoints about development: universal, universal with special characteristics, and non-universal. These views translate into these statements: the gifted are like all children (universal); the gifted are like all children and yet (some) have some special quality, too (universal with special characteristics); and the gifted are like persons who develop within a narrow domain of talent and few among them will be unique (non-universal). Here, we are using the term unique in a narrower sense than it is commonly used to convey the idea that some persons present an idea, model or performance that transforms a field.

The most common view, the universal, is that development of gifted children proceeds like that of all children. Typical development is an observable pattern common to all humans. In this category, whatever giftedness is, is generally accepted as development advanced from the expected pattern. Much of Terman's pioneering work can be seen as an attempt to show the universality of development of gifted children. A number of theories propose patterns of development that fit into the universal developmental view, e.g. Piaget, Erickson, Maslow, Kohlberg who speak of cognitive, identity, personality, and moral development respectively. Interestingly, these well-named theories are treated as independent from each other in most discussions of the gifted pertaining to their social-emotional development. Few acknowledge an association or interrelationship among them (Gowan, 1972; Coleman & Cross, 2001.) Although unevenness across developmental theories seems possible, it is their universality that is important.

Feldman (1980) identified four assumptions or criteria that are characteristic of universal developmental theories: universal achievement, spontaneous acquisition, invariant sequence and hierarchical integration toward transition. Note that the first two assumptions include all persons and are relatively independent of societal variations. It is this freedom that makes them universal and why they are applicable across a wide range of societal conditions. Regardless of the specific theory one accepts, buying into a universal theory means one accepts the assumptions underlying theories of that kind. Another smaller group which is growing in popularity in the field also speaks of universal patterns. This group sees gifted persons as possessing some quality or attribute more so than non-

gifted persons (Silverman, 1993; Morelock, 1996). Gifted persons are believed to experience living more intensely and more deeply. Piechowski (1991) maintains that these differences mean the gifted are qualitatively different. Integral to this view of development is the notion that these qualities promote the emergence of discontinuity or asynchrony in the universal developmental patterns. Asynchronous development is thought to be fueled by increasing levels of cognitive complexity (IQ is the metric) and by universal internal psychological mechanisms that are more evident in the gifted (Dabrowski, 1967). The interplay of cognition and internal mechanisms is important. The idea that children with the highest IQs experience emotional difficulties reminiscent of 'older' persons at earlier ages has been observed for many years (Hollingworth, 1926, 1942). However, the corresponding idea of internal mechanisms driving development has roots in Freud, Maslow and other theorists, but here Dabrowski's Theory of Positive Disintegration is influential. In his theory, inner conflict builds tension that fuels further development. Heightened sensitivity to certain kinds of stimuli (overexcitability) yields tensions that propel development. In this process the individual influences his own development. Within the gifted group individuals can be further distinguished by increasing levels of cognitive complexity and sensitivity. While development proceeds along the same lines for all, the particular characteristics of the gifted (IQ and intensity) make the gifted group qualitatively different and hence their development is different. The proponents of this view refer most often to examples of highly gifted persons and maintain they are more concerned about social-emotional development than accomplishment (Morelock, 1996).

The third group, the smallest in the field, sees development as non-universal and links development to the emergence of advanced, specialized kinds of abilities or talents in relatively few persons. The non-universal perspective proposes the idea that development is not solely in the person (like the other positions) but is also governed by the structure of the domain in which the advanced development is evident. Persons in that field (e.g. music, mathematics) go through an invariant sequence with increasing levels of complexity and increasing time devoted to practice. Nonuniversal development does not happen spontaneously in the course of living. Rather a person must make a commitment (e.g. by devoting time and practice) to the field. Not all persons have the opportunity, nor take the opportunity, for such development. Because of this purposeful dimension, non-universal development is susceptible to social variation. This is in marked contrast to universal development that is resistant to social forces, hence its universal quality. The theoretical proponent behind non-universal development has been David Feldman

(1980), although our interpretation of it as a means for understanding social-emotional development is not (Coleman, 1985; Coleman & Cross, 2001). The non-universal concept forwards the notion that commonalities will exist among persons in a field and reserves the notion of uniqueness to be applied to those few persons who alter the parameters of a field or create a new one. A significant feature of non-universal development is that rapid advances in development are regarded as normal rather than departures from normal. This view was developed based on the study of prodigies and the use of case studies (Feldman, 1991).

### **Moving From Influences to Theory**

We have discussed needs, characteristics and issues in terms of exogenous, endogenous and their interaction with the environment and in terms of researchers' conceptions of developmental trends and influences. What do the three conceptions of development have to do with dealing with the social-emotional issues that some children experience? That is hard to answer. The notion that gifted children have special needs is present in many of the popular texts in the field (Webb, Meckstroth & Tolan, 1982; Silverman, 1992; Gallagher & Gallagher, 1994; Clark, 1997). (For purposes of clarity we are not discussing educational needs in this chapter.) Webb and colleagues make a distinction between endogenous needs originating from the individual and exogenous needs that are byproducts of specific characteristics being present in an environment. Their dichotomy is a useful way to think about some individuals in their particular lives, but we suspect that the distinction tends to reify endogenous characteristics in a way that leads to confusion about social-emotional development of persons who are gifted. From our interactionist perspective, personal characteristics have psychological and phenomenal meaning primarily in sociocultural contexts. For example, in conversations among advocates for the gifted it is not uncommon to hear, "I think Mary's passion for dinosaurs is an indicator of attention span, curiosity, and imagination, but others view her passion as obnoxious, obsessive and not gender appropriate." This illustrates that characteristics have primary meaning when linked to living in the world and it is debatable whether the needs are endogenous. That some children who are gifted and talented have social-emotional problems and need assistance in coming to terms with themselves is undeniable. As previously noted, the three characteristics that get the most attention (perfectionism, multipotentiality and developmental differences between cognitive and affective growth) are interpretable as either endogenous or exogenous. Helpful suggestions can be found for practitioners and parents for dealing with those problems. However, acceptance of the existence of these problems does not mean that the majority of gifted children have variants of those problems. To make such an inference distorts

and dilutes the meaning of those problems. Furthermore, it is also unclear how the presence of those problems influence later development. Are our conventional assumptions about long term influence valid? Obviously, much more needs to be learned.

### **The Relationship Between Social-Emotional Development and Experience**

What does this situation mean for our understanding of social-emotional development? Where do we go with these competing views of social-emotional development? How do they help us understand gifted persons? We endorse a postmodern view that the three views of social-emotional development tell us somewhat different stories about the phenomenon of social-emotional development. Obviously, universal developmental milestones are evident in gifted child. Also, we see some characteristics that seem exaggerated in some gifted children and we do not know why they are present. And, lastly, some of those considered gifted or talented seem to be best described by non-universal theory. We conclude that it would be premature to proclaim that there is or can be a unified theory of the social-emotional development of the gifted that can help us understand those persons and guide the implementation of appropriate educational and counseling programs. The following recommendations for learning more about social-emotional development will contribute to the creation of a new, more encompassing theory.

#### *Moving Toward Personal Experience*

In order to move toward greater understanding of the development of giftedness in general, and social emotional development in particular, we need to study development in ways that have not been typically done (Coleman, 1995, 1997.) More systematic inquiry is needed in all three developmental theories, but the latter two deserve more effort. In our view universal developmental theory is unlikely to yield significantly deeper understanding of giftedness than it already has. Our knowledge has been relatively static in that area for decades. We use the term static not in the sense that useful research is not going on, but rather that what is studied are finer and finer delineation of aspects of development that have yielded small dividends. One area that seems tied to the idea of universality is the study of the construct self-concept. Researchers continue to gather data on this elusive idea (Hoge & Renzulli, 1993).

More research needs to be focused on the latter two theoretical perspectives (universal with special characteristics and non-universal) to see what new insights they might provide. Research centered on the lives of gifted persons seems to be a potentially fruitful area. While the experience of giftedness has been studied over many years, we consider the personal experience of being gifted or talented, especially through child-

hood, as a relatively unexplored area because the actual experience of the persons from the perspective of those persons has been missing. One exception would be autobiographies of persons who are gifted.

To understand social-emotional development, we need to understand more closely the personal experience of persons who are gifted. The pressures, joys, worries, conflicts and satisfactions of the experience of being a person who is gifted in various settings can become known as we gather evidence from empirical studies, biographies, clinical stories, life stories, etc. The experience of development contains much of the evidence of what social-emotional development is for this group and for subgroups. Our interest in this topic of experiences drives us toward two approaches to research described below.

#### *Two Avenues of Research on the Experience and Giftedness*

Experience of being gifted can actually be approached in two different ways. One approach is to try to explicate the experience of being gifted by understanding gifted students' understandings of their experiences. The other approach focuses on the lived experience of being gifted. 'Lived' experience is a term that phenomenologists use to illustrate the fact that people exist in the world in a primary way ahead of the establishment of second order meaning through symbols. Both approaches are similar in that they attempt to understand the meanings of the persons in a social setting. What distinguishes these approaches is when and where the researcher enters the life of the developing person. The experience of being gifted explores the meaning of the categories, symbols, and stories of one's life as people have reflected on them. On the other hand, lived experience explores the immediate experience of a person before meanings have been assigned to the experience (Van Manen, 1990; Holdstein & Gubrium, 1994). The former kind of research has a theoretical base or is moving toward one; the latter is atheoretical in the sense that experiences of people are their own. The two kinds of research are discussed below.

#### *Research on the Experience of Being Gifted*

The experience of being gifted has been pursued for many years by numerous researchers (e.g. Sanders, 1996; Bloom, 1985; Coleman and Cross, 1988; Cross, Coleman & Terharr-Yonkers, 1991; Csikszentmihalyi, Rathunde & Whalen, 1993). The approaches taken have included interviews, histories and biographies. Many important ideas and theories have emerged from these studies. In addition, the techniques used by researchers in this area have shed light on the relationship between the approach taken and what can be known as a consequence of an approach. For example, Csikszentmihalyi, Rathunde & Whalen, (1993) popularized the use of pagers as a means for

collecting important data in a random but systematic fashion from a group of subjects, but without hampering the external validity of a study that comes from reducing the extent to which subjects are in their natural environment due to experimenter influence. In this study the researchers asked gifted teenagers to wear a pager and write down where they were and what they were doing several times a day when the pager was randomly signaled. Sanders (1996) conducted a study that attempted to tell the life histories of several very accomplished college students. Each person's individual story was portrayed with the researcher providing an analysis of the social historical context of their lives. Gardner has produced books containing histories of very prominent people. Their histories provide great detail of their experiences as the subjects made sense of them.

One of the best known studies on the experiences of gifted people was published by Bloom (1985). In this book, Bloom reported the interviews of eminent people in several professions. As in the previous examples, details about gifted persons' lives were revealed in a manner that has affected both what we currently believe about the highly successful gifted adult person and how we go about conducting research.

From earlier research on the experience of gifted students in school, we developed an Information Management Model (IMM; Coleman & Cross, 1988). The IMM was built on previous research that yielded a Stigma of Giftedness Paradigm (SGP; Coleman, 1985). The SGP underpins the IMM by providing insight in the social cognition of gifted students.

### *Stigma of Giftedness Paradigm*

Coleman (1985) articulated a stigma of giftedness paradigm based on Goffman's stigma construct (1963), which asserted that being tainted (in this case, identified as gifted) makes apparent to other people a set of variables which influence the tainted person to alter the way he or she typically interacts with others. The SGP has three tenets: (1) gifted students desire normal social interactions; (2) they learn that others will treat them differently when they learn of their giftedness; and (3) they learn to manage information about themselves in order to maintain normal social interactions. Implicit in this theory is the existence of social cognition in gifted students.

There is another important idea underpinning this paradigm. That is, unlike certain stigmatizing qualities, i.e. visible differences one might have from a group of others, giftedness is only potentially stigmatizing; it can be masked or hidden. Consequently, researchers have tested the notion that gifted adolescents who feel threatened by the potentially stigmatizing association with giftedness attempt to control the information about themselves they make available to others (e.g. their score on a test) (Cross, Coleman & Stewart, 1993). Their findings supported the validity of tenets

two and three of the Stigma of Giftedness Paradigm. This controlling of information about oneself is considered a behavioral manifestation of social cognition (Cross, Coleman & Terharr-Yonkers, 1991). Some evidence does exist, however, that not all gifted adolescents control information others are allowed to have about them (Coleman & Cross, 1988; Cross, Coleman & Terharr-Yonkers, 1991; Cross, Coleman & Stewart, 1993). At this point we do not know how to account for these differences.

### *Social Cognition*

Social cognition is a person's psychological mechanism for understanding social situations and the subsequent strategies created to reach desired outcomes (Shantz, 1977). According to Rice (1990), social cognition is "concerned with the processes by which children and adolescents conceptualize and learn to understand others: their thoughts, emotions, intentions, social behavior, and general point of view. Implied in the concept of social cognition is an ability to make inferences about other people's capabilities, attributes, expectations, and potential reactions" (p. 105). In short, social cognition refers to reasoning about social situations while it guides efforts to reach social goals.

### *The Information Management Model*

From interviews with numerous gifted students about their experiences in school, an Information Management Model (see Fig. 1) was created. To follow the IMM one should read from left to right, first noticing a child approaching a specific setting. The IMM illustrates that in that student's mind are certain social expectations held for him/her. These expectations come from parents and teachers teaching them appropriate behavior for various settings (e.g. school, church). Upon entering school, the child creates an understanding of how to behave in accordance with expectations from the numerous cues. Whether a gifted student feels different from his or her peers will affect him or her. If the gifted child does not feel different (point A on the IMM), then he or she will have little need to develop social coping strategies. Studies have reported that some gifted students do not feel different from their nongifted peers (Coleman & Cross, 1988; Cross, Coleman & Stewart, 1995; Manor-Bullock, 1995).

Point (B) on the IMM reflects the fact that even though there are gifted students who do feel different, they do not develop social coping strategies per se. This point is debatable since many forms of coping strategies are quite subtle. In addition the strategies may originate as a strategy and later become a common part of the child's behavioral repertoire. Callahan, Sowa & May (1996) reported on this phenomenon by claiming that social coping strategies often later become more a part of the child's regular behavior and less of a specific coping strategy. Point C is where a

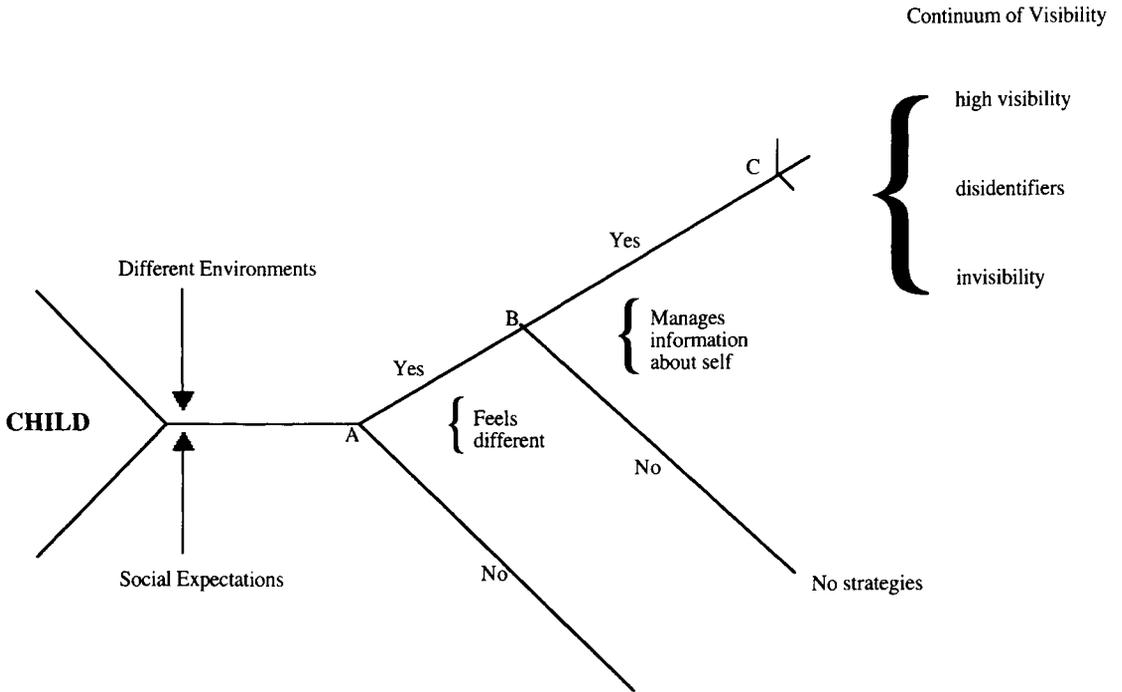

Figure 1. Management of Information Model.

gifted child feels different and engages in social coping strategies. The strategies can be characterized as falling on a Continuum of Visibility (see Fig. 2; Coleman & Cross, 1988; Cross, Coleman & Terhaar-Yonkers, 1991). The continuum was constructed to illustrate that, as gifted students act, they reveal social goals they have. The social goals can range from standing out further from other groups of students (high visibility) to becoming invisible (blending in with other groups). The third position on the continuum is called disidentifiers. They are strategies that attempt to convince others, by association, that the gifted student is really more like a group of students stereotypically not thought to be gifted. For example, gifted students have told us that certain groups of students in their schools are believed to be quite distinct from gifted students (e.g., burners, doper, skateboarders, jocks) (Coleman & Cross, 1988; Cross, Coleman & Terhaar-Yonkers, 1991). Hence, some gifted students chose to use

prevailing stereotypes held in their school culture to disidentify from being thought of as gifted.

Consequently, gifted students' behaviors in school reflect their self-perceptions in terms of feeling different or the same, and how they choose to act in order to maintain as much social latitude as they desire. Their idiosyncratic plan for social latitude is defined as their social goals. Their self-perceptions and subsequent behavior patterns also reflect their social cognition and the social milieu of the school. The Stigma of Giftedness Paradigm in concert with the Information Management Model provide useful tools for understanding why gifted students make certain choices about how to cope in school. These concepts were outcomes of the meaning of experiences of gifted students as they reflect on their lives. The students offered windows into their lives that were constructions based on interpretations of events and behaviors as influenced by the historical times in which they lived. To get at pre-reflective descriptions of lived experience, a different approach is necessary.

*Lived Experience*

Because social-emotional experiences are part and parcel of development, our knowledge of social-emotional development of the gifted requires access to the lives of persons. The study of the lived experience of being gifted can be carried out through phenomenology, a form of scholarly inquiry (Giorgi, 1983). In

Continuum of Visibility

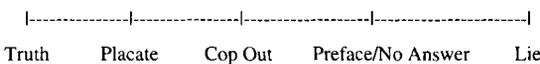

Figure 2. Continuum of Visibility.

phenomenology the connection between reality and the person is actively co-created such that there is no real distance between the two. A person's experience is what the world is to that person. Put succinctly, a person's subjectivity, not a denial of it, is the focus of study.

Phenomenology provides a means for entering parts of a person's life. By increasing our knowledge of the lived experience of being gifted, we will be advancing our understanding of giftedness itself. There are moments in person's lives when pathways change or diverge. In terms of the social-emotional development of giftedness, it would be useful to understand those moments. Several examples of such moments are presented below to convey the idea of what could be learned from this approach.

*Moment 1.* A person becomes aware that future development in an area or field requires a level of commitment that he or she does not want to invest.

*Moment 2.* A person who is gifted may have the ability to recognize something that outsiders do not, that is, he or she becomes cognizant that he or she does not have that special brilliance of another and must come to terms with that recognition. An example would be the moment in Amadeus when Soliari recognizes he cannot be a Mozart and must come to terms with that recognition.

*Moment 3.* Some persons are able to encounter the boundaries of a field and then transform that field. Is there an awareness of resistance to forces of conformity as a new way of approaching some field emerges? Is the person oblivious to outside influences in the pursuit of an idea or performance?

*Moment 4.* Feeling one's differentness has been reported by gifted persons. How is differentness experienced in circumstances where ability and interest is valued or devalued?

*Moment 5.* Moving toward excellence or originality is a part of some gifted persons lives. Is striving for excellence a nascent sensation that grows to some deeper awareness by the person during their life?

*Moment 6.* A person realizes that they are different from others who have common interests.

*Moment 7.* A person realizes an identity with another or others of similar interests and inclinations.

Each of these moments is fraught with personal significance. The apparent infrequency of these moments makes them appear mysterious, yet such experiences are part of being gifted for some persons. These are significant moments in development that the study of lived experience can open to scholarly inquiry.

Phenomenology can help us understand those moments better and deepen our appreciation of the social-emotional development of gifted persons (Cross, Coleman & Stewart, 1995).

### Summary

This chapter attempted to introduce a structure for understanding the social-emotional development of gifted students. We began by reviewing terms and issues about social-emotional development. We outlined a postmodern view acknowledging that the three types of development (universal, universal with some differences, nonuniversal) tell us different stories about the social-emotional development of gifted students. We also illustrate the benefits to the understanding of social-emotional development of gifted students of exploring the personal experience of the individual. Two avenues of research on the experiences of gifted students were also noted. They included research on the experience of being gifted as presented from the accounts of the students. The second avenue attempts to describe the lived experience of gifted students prior to the application of language attempting to approximate the experiential qualities. The nature of our understanding of the development of gifted students in the social-emotional realm will be significantly forwarded as we combine research on the lived experience with the universal with differences and nonuniversal developmental theories.

# A Life Span Approach to Talent Development

Ingrid Schoon\*

## Introduction

We would expect gifted individuals to do well in life, to apply their abilities fruitfully to the area of their choosing, and to succeed in the world of work. Yet, many individuals who are identified as gifted and talented during childhood or adolescence do not fulfil their promise in later life. This holds true for academic achievements in the school environment, for the pursuit of a professional career, and occupational success (Gardner, 1983; Subotnik & Arnold, 1993b; Simonton, 1998). Only very few young people become committed to the cultivation and realisation of their talent, while most equally gifted teenagers lose interest and never develop their childhood skills (Solano, 1987; Csikszentmihalyi, Rathunde & Whalen, 1993). How is budding talent transformed into adult achievements? Why do not all gifted children succeed in the world of work? What factors promote or hinder the use and realisation of childhood gifts? These questions have occupied a number of researchers and led to the identification of key factors which stimulate or inhibit the development of childhood potential. The aim of this paper is not to formulate another componential theory of talent development, but to outline a framework for synthesising the key spheres of influence that shape the pathways of gifted individuals. The first step will be to define the key concepts.

## Defining Giftedness

Over the last few decades the definition of giftedness has changed from being a one-dimensional conception linking giftedness to high intelligence to multi-dimensional conceptions acknowledging the existence of outstanding ability in different domains.<sup>1</sup> In opposition

to the notion of one general intelligence factor (Spearman, 1927), researchers have identified a number of relatively independent groups and subgroups of abilities (Thurstone, 1938; Guilford, 1956; Cattell, 1971). Synthesising available knowledge from psychometrics, cognitive psychology and neuropsychology Gardner (1983) has formulated the theory of multiple intelligences, identifying seven distinct 'intelligences' or abilities: linguistic, logical-mathematical, spatial, musical, bodily-kinesthetic, inter- and intra-personal. Gardner argues that all human beings are capable of several forms of knowing, and that individuals differ from one another in strength and combination of these intelligences, for both genetic and cultural reasons. Both cultural and developmental determinants affect which of the intelligences is emphasised, with a biological component determining inclinations and susceptibility to environmental shaping. Gardner assumes that each of the intelligences corresponds to a particular type of giftedness, and is a system in its own right with its own form of memory, learning, and perception. Thus, his approach suggests that giftedness is largely domain specific, and the search for general processes across domains would be unsuccessful. However, there is evidence that intellectually gifted individuals excel in other areas as well (Janos & Robinson, 1985; Gagné, 1995) and that there are some common higher order processes that operate across domains. Critiques of Gardner's theory have furthermore focused on the use of the word intelligence to describe what would more accurately be labelled gifts or talents. Intellectual giftedness as such has been defined in terms of multiple loci by Sternberg (1985, 1991). According to the triarchic theory of human intelligence intellectually gifted individuals recognize and advance their strengths, and they recognize and either compensate for or remediate their weaknesses. According to this theory individuals may differ widely in how they are intelligent, but they find some way in which they excel and make the most of it.

Noting that the terms giftedness and talent are often used synonymously Gagné (1985, 1993) suggested a differentiation between the two concepts, defining giftedness as exceptional competence in one or more domains of ability, and talent as exceptional per-

\* Department of Psychology, City University, London, UK.  
E-mail: i.schoon@city.ac.uk

<sup>1</sup> According to Csikszentmihalyi (1988, 1999) cultures are made-up of a variety of domains: mathematics, literature, dance, religion, music, etc. Each domain has its own set of rules, representations, or notations for instructing and assessing performance.

formance in one or more domains of human activity. Gagné specifies that genetically determined gifts form the infrastructure for talent development, while personal factors (such as motivation, interests, and personality traits), as well as environmental constituents (including parents, teachers, and the wider community), and systematic learning and training serve as catalysts for the expression of talent. Howe (1990, 1999) questioned the assumption of a genetic base to giftedness and suggested that outstanding abilities are not inborn but the product of a combination of personality, environment, and sheer hard work. He argues that gifted individuals are not fundamentally set apart from ordinary men and women, since the complexity and indirectness of genetic contributions to human activities and achievements rule out one-to-one relationships between genetic differences and ability differences. The debate about the role of nature versus nurture remains unresolved, yet there is a general consensus that multiple components must converge for outstanding achievement to occur.

Giftedness can therefore be defined as the potential for outstanding achievements, including cognitive, personal, biological, and social qualities of the individual. The development of exceptional abilities or talent in a particular domain can be conceptualised as the product of a combination of individual resources, a supportive environment, hard work, continuous training or practice. The processes by which individual potential is actualised into outstanding achievements are, however, not fully understood. Most theories of talent development do not relate directly to the major theories of development, and few describe the nature of environmental opportunities that nurture the realisation of potential (Horowitz & O'Brian, 1985; Mönks & Mason, 1993). Furthermore, most approaches investigating the realisation of potential only map the transition from childhood abilities to the formation of recognizable talents in particular domains, usually apparent from adolescence onwards and crystallising in a career choice (Feldman, 1992; Csikszentmihalyi et al., 1993; Gagné, 1993). Few researchers have investigated the experiences of young gifted people after their formal education has been completed, and still fewer have tried to describe and to follow the progress of gifted young people in the world of work. The current approach will address these issues, and outline a conceptual framework for analysing the influence of individual and contextual factors from a life-span developmental perspective.

### **Investigating the Realisation of Potential From a Life-span Perspective**

Developmental processes can best be investigated by studying individuals over time. The approach will therefore be a developmental one, trying to understand the development of gifted young men and women

beyond their school and college years, and to trace how the gifts of youths are transformed into adult attainments. Reviewing three, rather distinct perspectives on the developmental linkages between childhood giftedness and outstanding achievements in adulthood, Simonton (1998) concluded that a comprehensive theory of talent development must capture the intricate and dynamic exchange between genetic constitution, contextual influences, and the individual's distinctive intellectual and motivational make-up together with their social maturation. Biological, sociological, and psychological aspects all have an explanatory part to play, and one cannot be considered in isolation from the others. To bring together the multitude of factors influencing the realisation of potential within a comprehensive framework is a major challenge. By adopting a 'life-span view of human development' (Baltes, Reese & Nesselrode, 1977; Baltes, Reese & Lipsitt, 1980; Featherman & Lerner, 1985; Baltes, 1987), we find a conceptual and methodological framework that allows for the study of individual and contractual variables as well as their dynamic interaction within a wider context.

Life-span developmental psychology is concerned with the description, explanation, and modification of constancy and change of behaviour throughout the life-course, underscoring the link between contextual change and individual development. Life-span psychology has been characterised by six theoretical propositions (Baltes, Reese & Lipsitt, 1980; Baltes, 1987). First, it emphasises that human development extends over the entire life-span, from conception into old age, and involves the mastery of successive life-span tasks in a series of contexts that have different importance and salience at different points in the life course. Second, development is considered to be multidimensional and multidirectional, since at any given time point, developmental outcomes can be both positive and negative in the sense of multifunctionality. Interactive functioning in earlier stages, for example, may generate protective and risk conditions for later phases of the life course. Third, development is not linear, incremental growth, but always consists of the simultaneous occurrence of gain and loss, of growth and decline. Any developmental progression involves at the same time new adaptive capacities as well as the loss of previously existing capacities. Fourth, within-person variability (plasticity) of the developmental course can take many forms, depending on the life conditions and experiences of the individual. Fifth, developmental processes are historically embedded, which means they are influenced by the socio-cultural conditions that exist in a given historical period and the way in which these evolve over time. Sixth, declaring contextualism as a paradigm, individual development is understood as the outcome of the interactions among three systems of developmental influences: age-graded, history-graded, and non-normative conditions.

Critiques of the approach have pointed out that none of these propositions taken separately are new, and conclude that life-span work has little to offer (Kaplan, 1983). In a response to this criticism Baltes (1987) stresses that the significance of the life-span approach does not lie in the individual propositions, but in the whole complex of perspectives forming a metatheoretical framework for the study of development. The coordination of the different propositions form a coherent system, or 'family of perspectives', that together specify the life-span approach. Like other developmental specialities, such as child development, life-span developmental psychology is not a theory but an orientation, providing a framework for the theoretical and empirical study of behaviour development.

Perhaps the best studied domain of life-span developmental psychology is the area of cognitive functioning within the theoretical scenarios of child development or aging (Baltes & Staudinger, 1996; Pasupathi & Staudinger, this volume). The life-span view of human development has also been adopted for the study of career development, which is conceptualised as one feature of a person's development (Vondracek, Lerner & Schulenberg, 1986). The life-span approach stresses the mutual embeddedness of individual and context, conceptualising development as the dynamic interaction between a developing or changing individual in a changing context. The notion of dynamic interaction implies that individuals influence the contexts that influence them, that no one level of analysis in isolation can be considered the sole cause of change. The notion of embeddedness addresses the multiple levels of analysis, e.g. the biological, psychological, social, and historical context contributing to human functioning. The levels do not function in parallel, as independent domains, but there is a dynamic interaction between the levels. Each level may be both a product and a producer of the functioning and changes at all other levels. Different contextual conditions will lead to different developments when different individuals interact in them, and the same attributes in individuals will lead to different developments when they interact in different contexts.

In the following, the significance of the life-span perspective for the study of talent development will be illustrated by drawing on examples from the literature that describe the interaction between individual and contextual factors which shape the pathways of gifted individuals. The chapter will conclude with the formulation of a dynamic interactional model of talent development integrating the various spheres of influence.

### Early Ripe, Early Rot?

Lewis Terman's pioneering study of gifted individuals is one of the few that followed individuals beyond their college years, and reports on the fulfilment of intellectual promise in mature adulthood (Terman, 1925;

Terman & Oden, 1947, 1959). 1528 eleven year old school children with an IQ of 140 or higher were identified and followed from childhood in the 1920s to midlife and beyond. The twofold purpose of the study was to investigate whether child prodigies are psychotic or otherwise abnormal and whether they burn out quickly, or whether precocious children become exceptional adults.

The study shows that intellectually superior children become successful and well adjusted adults, who proved superior to the average person in most respects.<sup>2</sup> Despite the fact that the study was based on a single-cohort design, comprising overwhelmingly middle- and upper middle-class Anglo-Americans, it generated a reliance on the use of IQ scores for the early identification of giftedness. The instrument used to select the superior children (the Stanford Binet Test) is, however, quite heavily influenced by socio-economic advantages, and it is difficult to say to what degree the obtained IQ of 140 or above may be in part a function of the excellent home background of these young people (Cattell and Butcher, 1968). Furthermore, the study did not operationalise contextual factors, but focused on individual differences in intellectual ability.

The accomplishments of the Terman sample were outstanding, but the study group did not produce a single truly prominent individual (Wallace, 1985).<sup>3</sup> Furthermore, the vocational accomplishments of the gifted women in the sample did not compare with those of men: they were in positions of lesser responsibility, opportunity, and remuneration than men (Terman & Oden, 1959; Feldman, 1984; Subotnik & Arnold, 1993b). Fewer than one-half were employed outside the home, and according to Terman & Oden (1959) opportunities for employment and for advancement were influenced by both the women's own attitudes towards work and the attitudes of society toward the role of women. They concluded that however efficient the tests may be in discovering exceptional ability, and whatever schools may do to foster the discovered individuals, it is the prevailing *Zeitgeist* that will decide, by the rewards it gives or withholds, what talents will come to flower. They recognised that adult achievement is influenced by many things other than the sum total of intellectual abilities, and stress the importance of social class, educational attainment and personality traits which reflect ambition, self-con-

<sup>2</sup> The Terman sample tended to be of slightly better physique, healthier, more popular, less neurotic, more dominant, and happier with their lives.

<sup>3</sup> Simonton (1998) reports that William Shockley, Nobel Prize laureate for Physics, was among those tested in 1921 for inclusion in Terman's sample, yet his score on the Stanford Binet was not high enough to be considered as gifted.

fidence and all-round mental and social adjustment.<sup>4</sup> Yet Terman did not address how these factors are related, what impact they had at different stages of the life course, and how development is influenced by the historical context encountered by the sample members.

#### *Performance Potential in Context*

Considering any monistic theory of talent development as inadequate, Ginzberg & Herma (1964) tried to delineate the principal factors that played an important role in shaping the careers of gifted individuals. Subjects of the study were those individuals who had been awarded graduate fellowships at Columbia University between 1944 to 1951. This group of gifted or talented men and women were re-contacted in 1961, when aged between 34 and 44 years, and were asked to complete a ten-page questionnaire. Like Terman's study, this project had to concentrate on male graduates, because women had responded furiously to the carefully drafted questionnaire that gave them no opportunity to talk about their homes and families, or to describe the impact these aspects had on their career development.<sup>5</sup>

Ginzberg & Herma (1964) could identify a number of factors that influenced the extent to which gifted individuals, after completing their education, performed to a high level of competence. Original endowment, or mental prowess, proved to be one of the crucial factors for the level of accomplishment that an individual eventually reached. A second factor is the quantity and quality of the education, training and practice, and other preparations taken before starting to work. Thirdly, the ease or difficulty experienced in resolving the question of occupational choice was an important issue. Participants in the study who did not have a clear career aim had great difficulties negotiating their way through the complex and varied opportunities they encountered. Other key factors include individual motivation, attitudes, and values: those who seek to achieve the most will, other things being equal, achieve more than their peers who are less inclined to invest in the pursuit of their careers. Furthermore in order to succeed, individuals have to 'build bridges between the present and the future' (p.203), to develop expectations, and to project oneself into the future, constantly monitoring and adjusting their ideas and ideals. As a sixth factor Ginzberg and Herma mention the support received from the home

environment, as provided by the wife or the family of origin. Both can be a major source of comfort, but also of stress and difficulties. Finally, man does not live by work alone, and there are many opportunities to gain satisfaction from activities outside the work place. To invest some time and energy into avocational interests and activities can be rewarding and constructive in relation to work, while preoccupation with non-work activities can lead to lessening of accomplishments at work, and ultimately to an unsuccessful career. Thus the response to opportunities in the non-work area is another important factor related to the differential performance of talented individuals.

Underlying these factors Ginzberg and Herma identified a general factor similar to Spearman's G-factor, the 'performance potential', that gives shape and direction to the careers and lives of the generally successful gifted individuals. However, superior performance potential does not guarantee high level performance. Other determinants, such as the social reality, and the way in which the encountered reality is interpreted by the individual, must also be taken into consideration to understand the process of occupational development. Social disadvantage at birth, late completion of the doctorate, military service, marital troubles, numerous job shifts, or a unresponsive, poorly structured job market are some of the social reality factors that can impede a successful career. However, such experiences can also act as a spur, bringing new challenges and opportunities to the individual. Situational factors can always be perceived as dualities: as opportunities or limitations, demands or pressures, stimulation or temptation, encouragement or discouragement. The significance of any situation depends on its objective aspects and the manner in which the individual perceives and responds to it. Ginzberg & Herma (1964) stress that the way individuals respond to different situations, how they interpret the reality, can vary widely, and has to be understood as part of their total personality. They go further and identify two general principles that influence career development. One is the principle of accumulative (dis-) advantage, or continuity-cumulating tendency: getting off to a good start enhances the likelihood of becoming successful later, while the experience of bad luck at the beginning lowers the odds for being successful later on. The other principle is the functional equivalence of subjective factors (such as motivation), and environmental factors (such as a supportive and encouraging context or family background), which while being discrete phenomena, act at times as rough equivalents in the structuring of career development. Some individuals overcome apparently unsurmountable obstacles by determination, drive, and hard work, while others with less drive will reach the top if they receive strong support and encouragement.

This complex multidimensional framework integrates individual and contextual aspects, it includes

<sup>4</sup> A comparison of the 150 most successful and the 150 least successful males among the gifted subjects brought out four personality traits on which these two groups differed most widely: persistence in the accomplishment of ends, integration toward goals, self-confidence, and freedom from inferiority feelings (Terman & Oden, 1959, p. 149).

<sup>5</sup> This led Ginzberg to design a questionnaire specifically for women and to undertake a separate investigation into 'The Life Styles of Educated Women' (Ginzberg & Herma, 1966).

explicit measures of the social context, and describes processes that link the individual and context, covering some of the propositions central to life-span psychology (multidirectionality, plasticity, historical embeddedness). In contrast to the life-span approach that extends over the whole life-span, the model concentrates on the transition from college to work. It assumes an ideal, straight pathway from outstanding achievement in college to outstanding achievements in the world of work, and does not differentiate between age-graded, history-graded, and nonnormative conditions. Furthermore it conceptualises individual and contextual factors as discrete phenomena that can act as functional equivalents, and does not account for their mutual embeddedness meaning that individuals can influence the contexts that influence them. It should also be remembered, that, the model is only based on the experiences of gifted men, as other studies of that time.<sup>6</sup> A comprehensive model of talent development has to account for the experiences of both men and women, and seek to describe how men and women respond to the demands and opportunities they face as they move through life.

#### *Pathways of Gifted Women*

The women in Terman's sample equalled or excelled men in school achievement, yet they ceased to compete with men in the world of work, due to lack of motivation and opportunities not a lack of ability (Subotnik & Arnold, 1993b). Women seeking a career outside the home at that time had to break through many more barriers and overcome many more obstacles than did men on the road to success.<sup>7</sup> Tomlinson-Keasey (1998) describes the careers of the Terman women as random, marked by improbable and serendipitous events. Their careers were buffeted by social and societal forces, with their husbands', children's, and even parents' needs often taking precedence over their own career plans. Some women gave up successful careers when the chance for a meaningful relationship arose, or when the demands of their family could not be combined with work commitments. The late 1970's saw the launch of new equal opportunity programmes with aims to help and assist diverse groups of women to fulfil their potentials,

especially targeted to identify and to overcome internal and external barriers to success. Yet women, and in particular gifted women, remain underrepresented in the higher ranks of the professions (Card, Steele & Abeles, 1980; Eccles, 1985; Kerr, 1985; Subotnik, Karp & Morgan, 1989; Arnold, 1993; Subotnik & Arnold, 1993b; Tomlinson-Keasey, 1998; Schoon, 1999). This worrisome fact indicates an underdevelopment or underuse of the intellectual talents of women who would otherwise be fully participating and contributing in a variety of settings, and has stimulated a number of researchers to investigate further the reasons for the incongruence that exists between women's abilities and their occupational attainment.

#### *Is There a Measure of Successful Adult Attainments?*

Defining success of adult achievement is generally a value-laden endeavour, involving a variety of criteria that reflect both objective and subjective evaluations: income, occupational status or rank, responsibility, status of the employing institution, personal productivity, or personal reputation. Sir Francis Galton (1869), for example, considered the social and professional life as a continuous examination, and success in proportion as the general estimate of aggregated merits. He defines reputation as 'the opinion of contemporaries, revised by posterity' (p. 37). Terman & Oden (1959) have stressed that 'greatness of achievement is relative both to prevailing patterns of culture and the individual's personal philosophy of life; there neither exists nor can be devised a universal yardstick for its measure' (p. 151).<sup>8</sup> Evaluating the meaning and consequences of sex differences in achievement is equally complex and value-laden. Too often a male standard of ideal achievement has been adopted when judging the value of achievements by women, asking 'why aren't women achieving at the same levels as the men?' (Eccles, 1985; Tomlinson-Keasey, 1998). Suggesting that the traditional definitions of achievement are stereotypically masculine, Eccles (1987) inspired a number of researchers to rethink definitions of achievement and success from a female perspective that is substantially different from men.

Generally women's career choice and commitment to work differs from that of men, and is distinctly influenced by the effects of life role expectations (Arnold, 1993b). Longitudinal studies of women's career development showed that women, unlike men

<sup>6</sup> For example Vaillant's (1977) study on the coping mechanisms of Harvard male graduates for decades after graduation. Vaillant could show that the way the cohort dealt with inevitable life difficulties is a key characteristic in explaining the profound differences in career achievement that separated gifted undergraduates from one another in later years. Yet, he cannot explain how specific adaptation or coping styles emerge, but points out that they are multidetermined, depending on a blend of conflict, inner strengths, and earlier outside help.

<sup>7</sup> Terman's study describes a cohort of women growing up in a time prior to the women's movement, the occurrence of dual career couples, and the single-parent family.

<sup>8</sup> Asking their respondents 'From your point of view, what constitutes success in life?' Terman & Oden (1959) identified a wide range of definitions. The five most frequently mentioned definitions of life success are: a. realisation of goals, vocational satisfaction, sense of achievement; b. a happy marriage and home life, bringing up a family satisfactorily; c. adequate income for comfortable living; d. contributing knowledge or welfare to mankind; e. peace of mind, well-adjusted personality (p. 152).

who progressively narrowed their career choice, pursued a 'contingency approach' with plans remaining open and shifting in the face of imagined constellation of future personal and professional roles (Almqvist & Angrist, 1993). Rather than following an optimum career sequence, careers of women are characterised by several viable options that call for attention as the life course unfolds (Giele, 1982; Gilligan, 1982, 1991; Lubinski & Benbow, 1993; Tomlinson-Keasey, 1998). Findings from Hollinger & Fleming's (1992) study suggest that gifted women define achievement differently, placing equal value on personal and relational accomplishments as well as on career or educational achievements.

#### *Life-role Expectations and Life-Style Choices*

A number of studies suggest that intimacy is as central to women's lives as achievement is to men's lives (Gilligan, 1982; Harris, 1992; Hollinger & Fleming, 1992; Arnold, 1993a; Tomlinson-Keasey, 1998). It has been argued that women choose domains that are perceived as more person-oriented, affectionate and compassionate, involving interaction with people, while males prefer areas that have an image of being forceful, analytic, ambitious, individualistic and competitive, dealing with things rather than people (McClelland, 1975; Colley, 1995). In a longitudinal study of men and women who graduated from medical school in the 1980's Inglehart, Brown & Malanchuk (1993) showed that women entering medicine placed a higher emphasis on helping as the motivating factor for their occupational choice, while men stressed the reputation and status of the profession as well as the financial possibilities. In a sample of successful women, Gilligan (1982) found that women seldom mentioned their academic and professional distinctions, but rather described themselves as a mother, lover, or wife, focusing on the care they give to relationships rather than their achievements. In a follow-up study of 173 women who had been identified as gifted in their childhood (IQ greater than 132), and who finished college in the late 1960's, Tomlinson-Keasey & Blurton (1992) asked the same questions that the Terman women had answered at approximately the same age. This sample of women attached significantly more value to their careers than Terman's women. Although family life was rated lower in importance than in Terman's sample, the family was still regarded as their top priority, confirming the continuing importance of relationships, intimacy, and commitments among contemporary women. Arnold (1993b) shows that while the majority of young gifted women maintain a commitment to both relationships and careers, this dual priority can mean that each alternative is not pursued with the same dedication as a single goal. She stresses that values and life role expectations are the key to occupational attainment of gifted women, not ability, motivation, and academic

performance which although necessary are not sufficient to explain adult vocational achievement. Being able to see a potential self that combines high level career attainment with successful relationships allows gifted women to balance public and private spheres, work and family life. Arnold emphasises that aspirations<sup>9</sup> are crucial for the realisation of potential insofar as they enable or constrain self-images as aspiring career achievers.

These findings illustrate differential outcomes and adult achievements for gifted men and women. Early identification questions are not that crucial for capturing the pathways of gifted women. It is more the question of how giftedness develops across the life-span, and the kinds of achievement it leads to, that is of central importance. Gender role beliefs and stereotypes influence both expectations for success and the subjective evaluation of various life-style choices. Factors influencing the development of gifted individuals cannot be seen in isolation, but rather in relation to other spheres of life. The research findings indicate just how intertwined individual and contextual factors are, how their embeddedness in a wider socio-cultural context determines the pathways of gifted young men and women, and how different factors influence decisions and choices at different time points of the developmental process.

#### **Towards a Model of Talent Development**

Selecting key variables recognised as relevant for the development of budding talent, in both men and women, and bringing them together into a framework, the following model of talent development can be formulated (Fig. 1).

The model describes a setting for investigating the realisation of individual potential in a wider socio-cultural context. It adopts a life-span approach of development, as specified by Baltes (1987), Baltes, Reese & Lipsitt (1980), Vondracek, Lerner & Schulenberg (1986). The model differentiates between individual factors, conditions at birth, environmental factors, and the wider socio-historical and cultural context. Education, training, and practice take a special position, linking early and later stages in the process of talent development.

#### *The Socio-Historical Context*

The course of individual development is dependent on one's location in historical time, and the overarching cultural and economic context. Societal circumstances beyond the control of the individual contribute con-

<sup>9</sup> Aspirations or occupational choices are generally considered as an expression of a person's self concept, or more specifically self-perceptions (Super, 1980; Gottfredson, 1981).

siderably to the development of potential, and a major task confronting the gifted individual throughout the life-course is to cope effectively with the changing social reality. It has been stressed that we cannot understand the phenomenon of outstanding achievements by isolating individuals and their work from the socio-historical context in which their actions are carried out (Csikszentmihalyi, 1988; Simonton, 1987, 1997). The socio-historical context can spark ideas, nourish or suppress talent, and is crucial for the evaluation of ideas (Sternberg & Lubart, 1991). The prevailing Zeitgeist, or spirit of the times might cry out for the development of a particular ability, while at other times, or in other cultures, the same competence might be considered as of no particular value.

*Achievements in Adulthood*

Adult achievements refer to accomplishments at a stage in life and thus do not portray a life trajectory or pathway to particular achievements. In the model, the variable ‘achievements’ includes occupational

attainments, but also takes into consideration other indicators, such as qualifications, status or income, a harmonious family or personal life, or general satisfaction with life. Such a broader conceptualisation of adult accomplishments accounts for the different definitions of achievements and success mentioned before, and takes into consideration the various domains of human activity in academic, artistic, or inter- and intrapersonal fields. High status, the realisation of educational and vocational goals, a happy family life, and a well adjusted personality are positive outcomes in themselves, but they are also intricately linked to each other. For example, good qualifications enable entry to prestigious occupations; the process of participating in further education itself can widen and deepen personal interests and might lead to a general contentment or satisfaction, while also opening up opportunities to meet potential partners for relationships or other support networks. On the other hand, good qualifications can coincide with unemployment, and might thus lead to discontentment and feelings of frustration.

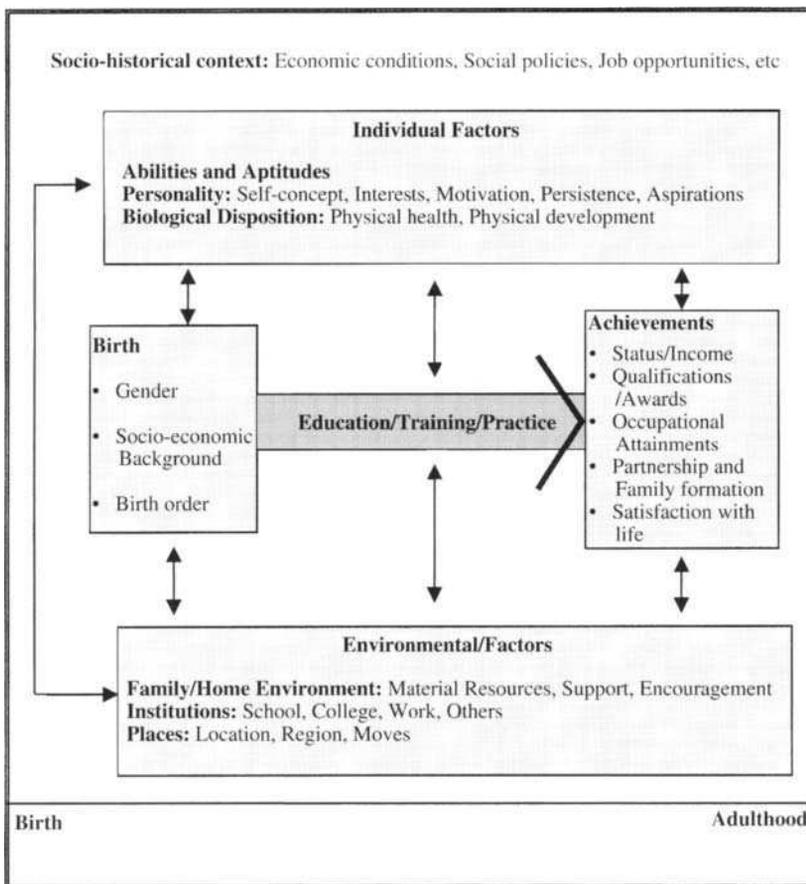

Figure 1. A dynamic-interactive model of talent-development.

Likewise the family of procreation can be a major source of life satisfaction and support in attaining one's occupational aims, or it can be the centre for difficulties and disturbances that drain one's energies (Ginzberg & Herma, 1964; Subotnik & Arnold, 1995). Thus outcomes at different life stages are linked with each other, they can always be perceived as dualities, and they can influence or become part of the environmental or individual factors influencing the ongoing process of development.

### *Individual Factors*

Inter-individual differences in achievement are based on a mixture of aptitudes and abilities, personality characteristics, motivation and biological disposition, as well as the interaction of these factors with environmental factors and their embeddedness in a wider socio-cultural context. Specific aptitudes and abilities are a necessary but not a sufficient precondition for achievement in various domains. Determination and persistence in pursuing an ambition, or willingness to work hard for realising one's potential is another key ingredient (Terman & Oden, 1959; Ginzberg & Herma, 1964; Bloom, 1985; Renzulli, 1986; Heller, 1996; Heller & Vieck, 1999). Aspirations, in particular, play a crucial role in linking potential to fulfilment. Recognising and exercising one's own interests, competencies, and values, individuals formulate expectations by projecting oneself into the future. The formulation of such a life plan (Ginzberg et al., 1951) helps to direct and guide the transition from present to the future. Yet, expectations and aspirations might change depending on the social reality the individual encounters. Compromises might be necessary, adjusting aspirations that were either too high or too modest (Ginzberg & Herma, 1964; Gottfredson, 1981; Heckhausen, 1999).<sup>10</sup> Other personality characteristics such as autonomy, independence of thought, and self-confidence also play a key role in linking promise to fulfilment (Roe, 1953; Terman & Oden, 1959; MacKinnon, 1960, 1965; Gagné, 1993; Heller, 1996) and are included in this model. We also have to consider the role of biological dispositions as a underpinning of both giftedness and outstanding achievements in adulthood. General mental and physiological health have been identified as important factors facilitating the realisation of potential (Terman & Oden, 1959; Janos & Robinson, 1985). On the other hand, individual giftedness has been linked to psychopathology for centuries, and recent evidence seems to

support such a link (Eysenck, 1995; Prentky, 1989). Yet, Eysenck does stress that 'many other conditions must be fulfilled, many other traits added (e.g. ego strength), many abilities and behaviours added (e.g. IQ, persistence), and many socio-cultural variables present, before high creative achievement becomes probable' (Eysenck, 1995, p. 279).

Thus, those individuals who have the aptitudes, the disposition, the motivation, the belief in their own capacity, and who show personality characteristics appropriate to the demands of a special field<sup>11</sup> will try to make the most of their potential. Yet, the question also why so few individuals realise their potential cannot be answered by looking at individual factors alone, but depends as much on the social realities experienced by the individual.

### *Birth*

Individuals are born as male or female, to more or less privileged parents, and into small or big families. All of these factors influence their consequent development. Gender differences in the development of talent are well documented and analysed, and some findings have been discussed earlier. Research on birth-order effects has shown consistent evidence that birth-order influences the emergence of exceptional ability in both childhood and adulthood (Galton, 1874; Terman, 1925; Roe, 1952; Chambers, 1964; Simonton, 1987). Social background is associated with educational aspirations, occupational status aspirations, and occupational status attainment (Blau & Duncan, 1967; Oden, 1968; Sewell, Haller & Ohlendorf, 1970; Zuckerman, 1977). Getting off to a good start, for example being born into a privileged family, can mean an increased likelihood of becoming successful later. A favourable objective situation creates opportunities that facilitate the realisation of ambitions and potential. The socio-economic and educational background of parents has shown to be a good indicator of the kind of intellectual interests encouraged in the child (Getzels & Jackson, 1961) as well as for educational achievement and occupational attainment (Trost & Sieglen, 1992; Tomlinson-Keasy, 1998). Individuals from more privileged homes have more educational opportunities, greater access to financial resources when they need them (i.e. to pay for higher education), role models, occupational knowledge, and informal/kinship networks (Schulenberg, Vondracek & Crouter, 1984). The same cumulative effect, in the opposite direction though, can occur for those who are not born so lucky and who consequently acquire an enhanced likelihood of risk, or bad luck. This principle of accumulative advantage or dis-

<sup>10</sup> Ginzberg & Herma (1964) emphasise the importance of recognizing when to adjust one's expectations: some individuals are more adept than others in profiting from their experiences and in adjusting their expectations when necessary, while others may waste much of their energy running after illusions, while still others might settle for too little.

<sup>11</sup> The term 'field' describes the social organisation of a domain. A field is made up of individuals who practice a given domain, who have the power to change it, or to act as 'gatekeepers' (Csikszentmihalyi, 1988, 1999).

advantage<sup>12</sup> has been described by Ginzberg & Herma (1964), and also by Merton (1968). What is not known, is how far the pathways between childhood circumstances and adult attainments are mediated through individual outcomes during the life course or through the continuous accumulation of (dis-) advantage which increases resilience or vulnerability of the individual to later problems. After all, some individuals from a disadvantaged family background break the vicious cycle (Elder, Pavalko & Hastings, 1991), while others from privileged backgrounds fail to succeed.

### *Environmental Factors*

Much of the available information about the impact of external factors on the development of talent over the life course comes from Bloom's (1985) retrospective study of outstanding individuals in a variety of domains. Bloom illustrated the changing nature of the dynamic interaction between individual and contextual factors across different life stages. He differentiated between early, middle and later years of talent development to demarcate important signposts along a long and continuous process. The development of exceptional levels of talent requires certain types of environmental support, special experiences, excellent teaching, and appropriate motivational encouragement at each stage of development. During the early years of childhood, the individual is introduced to the domain, usually through parents or kin, with an emphasis on play and enjoyment. During the middle years of training, competition and work receive more emphasis. At this stage parents seek advice and support from teachers, coaches, or mentors and continue to provide emotional support. During the later years a definite commitment is required, the individual pursues training and practice on a full-time basis. The development of talent becomes a life-long career combining work and play. During this period the talented individual usually works with a teacher or coach who can also perform at an exceptional level in the relevant domain. Lack of economic and social support from parents, serious injury or disease, lack of teaching and encouragement, and other social and medical problems make full dedication difficult or impossible. Bloom's findings emphasise the crucial role of tutelage, nurturance, and support, and downplay the role of genetic endowment as prime cause of high-level achievement. Furthermore, a strong interest and emotional commitment, the desire to reach a high level of attainment, and willingness to work hard are crucial qualities present in all fields of accomplishment. According to Bloom these are socialised qualities, learned in the home, from teachers, and sometimes from peers and siblings. They

can be acquired more easily if they are valued in the individual's immediate environment and should thus be encouraged and not undermined.

The school environment, for example, is powerful shaper or a deterrent to the development of individual potential (Mönks, Katzko, & Boxel, 1992). School activities, both inside and outside the classroom, the interpersonal relations with teachers, students, and other staff, the various roles and role expectations, and the physical, structural, and material features, all render the school environment a most important context shaping the expectations and outlook of young people (Vondracek et al., 1986). In the school context the individual has its first encounter with a structured social arena within which to experience the 'sense of industry', the consequences of social and academic competence, competition, and power relationships (Erikson, 1959). The school setting also prepares the individual for the world of work, providing information, advice, and experience relevant to the impending transition from school to work.

The experience of the world of work requires the developing person to become an active participant. Finding a job, changing jobs, losing jobs, or changing careers are major transitions in the life-course of every individual. The reason why some individuals are more likely than others to take action to achieve lies often in the nature of the chosen field, the necessary requirements for entry, and the structure of the organisations in which people work. Fields differ in the dynamics of their inner organisation, the stringency of their selective mechanisms, the sensitivity of the 'gatekeepers' who have wealth and power, or who are highly respected for their expertise (Csikszentmihalyi, 1988, 1999). Professional advancement structures, the funding climate for scientific research, and career constraints were identified as crucial factors influencing the career paths and achievements of talented individuals (Heller & Viek, 1999; Subotnik & Arnold, 1995). If there are not enough jobs, or opportunities, or social recognition to develop a domain related role, individual factors are insufficient to create viable careers.

### *Education, Training, Practice*

It has been emphasised by Gagné (1993) that learning, training and practice illustrate best the longitudinal dimension of talent development. Gagné describes the unfolding of aptitudes and talent on the basis of four developmental processes: maturation, daily use of problem solving situations, informal training and practice, and formal training in a particular field. Without general and specialised forms of education and training, individuals will be excluded from a number of occupations or opportunities, regardless of their endowment. The quantity and quality of the training and practice and other preparations that an individual undertakes in order to pursue a particular

<sup>12</sup> This principle is sometimes referred to as the 'Matthew effect' due to its link to the Gospel passage that says 'For to every one who has will more be given, and he will have abundance; but from him who has not, even that he has will be taken away' (Matthew 25:29 in Simonton, 1998).

career or life-style, are clearly influencing differential outcomes, as well as the ability to learn rapidly and well (Bloom, 1985). Education, training and practice takes a central position in the model, forming a link between the present and the future, and as a key area for possible interventions (Mönks, Katzko, & Boxtel, 1992; Mönks & Mason, 1993).

### Conclusion

The aim of the chapter was to develop a framework for investigating the development or realisation of childhood gifts in adult achievements. By adopting a life-span developmental perspective, and drawing on examples from the literature, a dynamic interactive model of talent development has been formulated. Talent development has been conceptualised as one feature of person development, fuelled by the dynamic interaction between a changing individual and a changing context. Key aspects shaping the pathways of gifted individuals are conditions at birth, individual characteristics, environmental factors and the wider socio-historical context. Participation in education, training and practice plays a central role, bridging earlier and later stages of the developmental process. The model provides a framework for investigating how giftedness develops across the life-span, and the kinds of achievement it leads to. It accounts for the changing social contexts confronted by the maturing individual, such as, the changes in the number and kind of interacting partners (family, friends, peers, teachers, colleagues), and it illustrates how experiences in one sphere may affect those in others.

The model still requires an elaboration of the different spheres involved. There is need for further research along several lines. Firstly approaches for delineating and evaluating the individual factors and their dynamic interaction need to be explored further. The processes linking ability, personality, motivation, and biological disposition have to be more fully examined. There is a need to develop new methodologies to investigate the reality of situations and the ways in which these are experienced and interpreted by the individual. Furthermore, the processes linking the different spheres have to be specified. Each sphere can have an impact on any of the others, and these relationships are bidirectional, which means that each sphere can both be product and producer of changes in other spheres. What we do not know is the relative influence of the different spheres on each other. There is also a need to define developmental markers, since one of the most important person characteristics is the location on the developmental path. As the individual grows older they become more able to transform, manipulate, or modify the environment with which they interact.

The model raises questions that have not yet been fully addressed and answered by research. There is clearly a need for comprehensive, longitudinal, multi-

wave studies of the processes and variables that shape the pathways of gifted men and women. Unlike cross-sectional studies that can measure inter-individual differences at one point in time, or retrospective studies that have to rely on subjective reports that can be distorted by hindsight, prospective longitudinal studies allow us to explore the processes of change. Longitudinal designs allow us to define giftedness as a potential, and to follow the development of this potential across time (Trost, 1993). They provide causal explanations for intra-individual change and for inter-individual differences in intra-individual change, and they enable the researcher to describe the interactions of developmental variables (Subotnik & Arnold, 1993a). By including all the individual and contextual variables that might have a significant longitudinal effect, the relative importance of various factors can be assessed in various contexts. Furthermore, by measuring all the relevant variables at several time points, the inter-relations among variables can be investigated.

Independently of the numerous clarifications that should be made to the proposed model, it is an important step to acknowledge the need for a developmental perspective that captures the dynamic interaction between a changing individual and a changing context. Many questions raised by previous research on the topic could be answered if we knew more about the developmental course of gifted individuals and the nature of the forces that shape and stimulate the realisation of giftedness and talent.

# Prodigies, Savants and Williams Syndrome: Windows Into Talent and Cognition

Martha J. Morelock\* and David Henry Feldman†

## Introduction

Although extraordinary talent is always intriguing, it is perhaps most fascinating when found where least expected. This chapter deals with three groups of individuals whose capabilities are surprising in this sense. All have captured the imagination of those seeking to understand the origins and development of talent. Child prodigies display astounding adult-like mastery of a demanding domain of endeavor. Savants manifest islands of extreme capability showcased against a backdrop of overall severely deficient intellect. In recent years, people with Williams Syndrome, who show major deficits in general cognitive ability, have attracted interest because of their astonishing innate abilities in music and facile use of language.

Over the last two decades, the domain-specificity characterizing talents in these groups has provoked awareness that our concepts of intelligence, talent, and handicap need to be revised (Feldman, 1980, 1982; Gardner, 1983; O'Connor, 1989; Feldman & Goldsmith, 1991; Lenhoff, 1998). It has become clear that to understand giftedness and talent, we must seek more precise articulation of the relative roles of general cognitive ability and domain-specific intellectual capacities as well as the interplay between them (Morelock & Feldman, 1993; Feldman, in press). Special groups such as these show promise of providing this understanding.

We begin this chapter with some general background about prodigies, savants and people with Williams Syndrome; the discussion then focuses on comparing their abilities in music—a shared talent domain. The chapter concludes by examining what we have discovered by juxtaposing these groups; possible directions for future research are also explored.

## The Prodigy

A prodigy is a child who, before the age of 10, performs at the level of a highly trained adult in some

cognitively demanding domain (Feldman with Goldsmith, 1991; Morelock & Feldman, 1999).

This precise definition of prodigiousness has only been in existence since 1979 (Feldman, 1979)—in spite of the fact that 'prodigy' was used loosely to refer to extraordinary youngsters for many years prior to that. Historically, the term was part of a prophetic tradition signaling impending change (Feldman with Goldsmith, 1991). It referred to an entire range of unnatural phenomena extending from the advent of notable uncanny or extraordinary happenings to the existence of humans or animals regarded as 'freak'.

Over time, the term began to be used more narrowly to refer to extreme human precocity (Morelock & Feldman, 1997). The 'sign' or 'portent' aspect of its meaning was dropped, while the essential connotation of 'unnatural' or 'inexplicable' remained. The term continued, however, to be used indefinitely to refer to a broad range of manifestations of precocity (Barlow, 1952).

With the advent of IQ and its widespread acceptance as the gauge of giftedness, the phenomenon of the prodigy became subsumed under the IQ umbrella (Feldman, 1979). Children who could compose sonata at the age of 6 were implicitly assumed to be high IQ children with penchants for given fields. Nevertheless, the four scientific studies of prodigies that have appeared in the literature<sup>1</sup> fail to support a straightfor-

<sup>1</sup> Although the literature contains only four systematic scientific studies of child prodigies, a number of biographical or psychohistorical accounts of the lives of prodigies have been published. See, for example, Kathleen Montour's William James Sidis: *The broken twig* (Montour, 1977), Norbert Wiener's 1953 autobiography, *Ex-Prodigy: My childhood and Youth* (Wiener, 1953); Amy Wallace's 1986 book (also about William James Sidis) *The Prodigy* (Wallace, 1986); Fed Waitzkin's 1984 book, *Searching for Bobby Fischer: The World of Chess. Observed by the Father of a Child Prodigy* (Waitzkin, 1984), and Claude Kenneson's

ward relationship between prodigious achievement and extraordinarily high IQ (Revesz, 1925, Baumgarten, 1930; Feldman, 1980, Morelock, 1995). Prodigies have been documented with IQs ranging from 120 (Baumgarten, 1930) to 200+ (Morelock, 1995). While IQ-associated verbal-conceptual reasoning alters the quality of performance across domains (Morelock & Feldman, 1993; Feldman, in press), the extent to which *large* endowments of general cognitive ability are necessary to talent development appears to vary according to the domain in question and the salience of IQ-independent components in performance. For example, the quality of a writing prodigy's work is heavily influenced by insights and perceptiveness arising out of abstract reasoning (see, for example, Morelock, 1995). However, no matter how great a child's abstract reasoning ability, musical talent cannot emerge without keen auditory perception and sensitivity. Indeed, as the talents of savants and many people with Williams Syndrome attest, impressive musical ability sometimes emerges in the absence of *average* general cognitive strengths, although certain skills of musicianship—such as reading music—appear to require IQ-associated competency (Miller, 1989; Lenhoff, 1998).

Feldman, as the result of his study of six child prodigies, became sensitized to the importance of such domain-specific requirements. He incorporated them into his theory of *Co-incidence*, which he constructed to explain prodigious talent (Feldman, 1980; Feldman with Goldsmith, 1991). Co-incidence, briefly defined, is the melding of many sets of forces interacting in the development and expression of all human potential. These extend from the level of the individual and his/her family to that of the domain and its requirements and on to the macro level of differential cultural opportunities for the development and expression of various talents. Child prodigies result from a fortuitous concordance of the forces of co-incidence leading to the maximization of human potential. Thus, in most cases of prodigiousness, a child of extraordinary native ability is born into a family recognizing, valuing, and fostering that ability when the child's introduction to the culturally available domain reveals its presence. The child is generally exposed to master teachers who instruct the prodigy in a way most likely to engage the interest and sustain the commitment of the child. Invariably, as well, the child demonstrates a combination of inner-directedness and passionate commitment to the field of achievement.

Prodigious achievement only occurs in domains accessible to children, requiring little prerequisite

knowledge and using media and techniques adaptable for a child's use (e.g. a child-sized violin must be available for a 6-year-old prodigy violinist). Most child prodigies are found in chess and music performance. There have been, however, child prodigy visual artists (Pariser, 1987; Goldsmith & Feldman, 1989), infrequently, a child prodigy in mathematics (Bühler, 1981), and occasional writing prodigies (Radford, 1990; Feldman, 1991; Morelock, 1995).

Having briefly touched on the literature pertaining to prodigious achievement, we turn now to consider the idiot savant.

### The Idiot Savant

The emergence of exceptional skill in people with mental disability has been documented in the literature for over 200 years (Foerstl, 1989). However, the term 'idiot savant', did not appear in the literature until 1887 when Dr. J. Langdon Down (1887) used it to refer to severely mentally handicapped persons displaying advanced levels of learning in narrowly circumscribed areas. In Down's time, *idiot* referred to individuals operating at the lowest level of retarded functioning based on an evaluation of speech and language capabilities (Scheerenberger, 1983).

With the development of IQ tests, idiocy became translated as encompassing the lowest portion of the IQ scale—extending over an IQ range of 0 to 20 (Craft, 1979). In reality, however, the IQs of all known tested idiot savants have been above 20—and usually fall in the range of 40 to 70 (Treffert, 1989). Somewhat more appropriate, but still a misnomer, is the second part of the term, 'savant'—a straightforward adaptation from the French word meaning 'to know' or 'man of learning'.

Because of the failure of 'idiot savant' to capture the essence of the savant phenomena and because of the pejorative connotations of the first part of the term, a number of alternatives have been suggested (Rimland & Hill, 1984; Charness, Clifton & MacDonald, 1988; Treffert, 1989). In 1989, Treffert proposed a more precise classificatory terminology and suggested a theoretical explanatory framework. He also proposed an alternative term for the condition: *savant syndrome*—or, more simply, just *savant*.

### Savant Syndrome Defined

As defined by Treffert (1989), Savant syndrome is a rare condition in which seriously mentally handicapped persons show spectacular islands of ability or brilliance standing in stark, markedly incongruous contrast to the handicap. In some, savant skills are remarkable simply in contrast to the handicap (talented savants, or savant I). In others, with a much rarer form of the condition, the ability or much rarer form of the condition, the ability or brilliance would be spectacular even if viewed in a normal person (prodigious savants or savant II).

<sup>1</sup> Continued  
account of the lives of a number of musical prodigies, including Mozart, Paganini, and Clara Schumann, in his 1998 book, *Musical Prodigies: Perilous Journeys, Remarkable Lives*.

Savant syndrome can be either congenital or acquired by a normal person after injury or disease of the central nervous system. The skills can appear—and disappear—inexplicably and without warning (Selfe, 1977; Treffert, 1989).

Like prodigies, savants occur only within a limited number of areas (Treffert, 1989; Young, 1995). Documented savant skills include: calendar calculating (e.g. the ability to quickly calculate the answers to such questions as “On what day of the week will April 29 of the year 2245 A.D. fall?”); music (chiefly limited to the piano); lightning calculating (the ability to do extraordinary rapid mathematical calculations); art (painting, drawing, or sculpting); mechanical ability; prodigious memory (mnemonism); or, on rare occasion, unusual sensory discrimination (smell or touch) or extrasensory perception. Prodigious savants occur chiefly within the areas of music, mathematics (lightning and calendar calculating), and memory (Treffert, 1989).

#### *Incidence of Savants*

The literature reveals two major populations from which savants emerge: (1) those diagnosed as autistic, and (2) those diagnosed as mentally handicapped, but not autistic. Rimland (1978) estimates the percentage of idiot savants in the autistic population as 9.8%; while the prevalence of savants in the mentally handicapped population is estimated to be significantly less—0.06% (Hill, 1977). As the incidence of autism itself is only 0.04% of births, however, autistic individuals are far less numerous in the general population than are mentally handicapped people (O'Connor, 1989). Consequently, in absolute terms, idiot savants emerge from each source in approximately equal numbers. Savant skills occur six times as often in males as in females (Hill, 1977).

#### *Features of Savant Functioning*

A number of features are common to all savant functioning:

*Impaired capacity for abstraction.* Scheerer, Rothmann, and Goldstein (1945) first documented the “impairment of abstract attitude” typical of savant functioning. The researchers noted that, generally, savants display minimal abstract reasoning ability combined with almost exclusive reliance on concrete patterns of expression and thought. They wrote of one savant who memorized and sang operas in several languages, yet had no comprehension of the abstract conceptual and symbolic meaning of words.

More recent research suggests that the question of abstract reasoning in savants is more complex than originally thought. Studies show that savants have an immediate—seemingly intuitive—access to the underlying structural rules and regularities of their domain, be it music (Miller, 1989; Treffert, 1989), mathematical calculation (O'Connor & Hermelin, 1984; Hermelin &

O'Connor, 1986), or art (O'Connor & Hermelin, 1987). Intriguingly, these are the same as those applied by practitioners of normal or high reasoning ability who are skilled in the same area. Thus, although most savants can't reason conceptually, all can abstract to a degree—at least in circumscribed and domain-specific areas (O'Connor, 1989; Miller, 1999). Miller (1999) suggests that what may be missing in savants is a conceptual system that can reconstrue or relate domain-specific knowledge in a more general framework, leading to a decontextualized representation containing less perceptual detail but better adapted to varied application in cognition.

*Lack of metacognition.* Savants lack the ability to reflect upon their internal thinking processes (Scheerer et al., 1945)—what is now called ‘metacognition’. When asked to account for how they can do whatever it is that they do, savants frequently respond with something strictly irrelevant. One calendar calculator, when asked how he managed his remarkably fast responses to date questions, said “I make all sorts of mathematical calculations, don't I?” In fact, he was usually unable to add or subtract without pencil and paper (O'Connor, 1989).

*Extraordinary memory.* All savants are notable for their extraordinary memories (Treffert, 1989). Indeed, the mnemonist savant's sole talent consists of impressive memory for miscellaneous or mundane happenings (e.g. some savants have been known to remember weather conditions for each day of most of their lives). In other savants, it is the norm for extraordinary memory to be limited to their domains of achievement.

*Flattened affect.* Savants exhibit a restricted range of emotion, or flattened affect (Treffert, 1989). The performance of musical savants, for example, frequently manifests this deficit by coming across as shallow, imitative expressiveness lacking subtlety or innuendo.

Music appears to be the only domain where there is some controversy about the ‘flattened affect’ observation (Howe, 1989; Miller, 1989; Treffert, 1989). There have been cases of musical savants demonstrating emotional connection with the music they were performing (Viscott, 1970; Miller, 1989). In one such case (Viscott, 1970), the savant possessed more expanded verbal abilities than is commonly the case in manifestations of savant talent. This may have allowed for an interpretive response to the music.

An additional consideration in the case of musical savants is the fact that emotional response to music may be, to some extent, the direct result of the physiological changes which it evokes (Winner, 1982). Music not only affects pulse, respiration, blood pressure, and the electrical resistance of the skin, but also delays the onset of fatigue (Mursell, 1937). These same

types of changes occur during emotional experience. The question is raised whether the emotional response seen in musical savants may be more a straightforward reflection of specific physiological effect than is the case with musicians more conceptually and interpretively involved with the music.

*Limited creativity.* Savants appear to be incapable of producing totally original work. For example, while a musical savant might imitate, improvise, or embellish based on pre-established constraining musical rules, he or she is generally incapable of composing (Treffert, 1989). Sacks (1995a) distinguished between two different kinds of creativity, acknowledging as creative the individuality of savant ability based on perceptual talent while recognizing that even the prodigious savant does not achieve a higher order of creativity—the invention of new ideas and new ways of seeing things.<sup>2</sup>

Along this line of thought—there is evidence that musical savants with more highly developed language capacities may be more likely to be able to compose music. Miller (1989) documented the development of language in L. L., a musical savant. Over a period of months, L. L.'s language skills evolved from simple monosyllabic or echolalic responses to conversational generation of requests, comments and more sophisticated responses to questions. At the beginning of this period, L. L. remained musically confined to renditions of songs and melodies of others, with little inclination to improvise or compose. When he and Miller met for the last time, however, L. L. announced and played an original composition. This curious concordance of the development of expanded language skills and the onset of musical creativity led Miller to speculate that music and language are not mutually exclusive.

*Cognitive profiles and family influences.* In what is the largest series of studies of savants to date, Robyn Young (1995) investigated the talents and family backgrounds of 51 savants recruited throughout Australia and the United States. The selection of savants included varying degrees of talent, including prodigious and talented savants as well as cases of 'splinter skills'—levels of interest and competence only margin-

ally above the level of general functioning. Young found that parents and siblings of the participants were an exceptionally able group, with above-average IQ and high frequency of high-level skills, though not necessarily the same skills as those displayed by the savants. In addition, there was a familial predisposition toward high achievement, possibly innate, which provided encouragement and reinforcement for savant skills. Young concluded that savants have an underlying biological predisposition towards high general ability that is tempered by neurological impairment. Furthermore, she found the level of precocity exhibited by a savant (i.e. prodigious or talented) to be positively correlated with level of general cognitive ability, as indexed by IQ.

In contrast to the generally held impression that savants manifest islands of extreme capability showcased against a backdrop of *overall severely deficient intellect*, Young found peaks and valleys in the WAIS profiles of her savant sample. Among her 51 savants, 16 had a subtest score at least one standard deviation above the population mean, and 60% had at least 1 subtest one standard deviation above the full-scale score. Block Design, Object Assembly, and Digit Span accrued highest scores; lowest scores were found on Comprehension, Coding and Vocabulary. Neither grouping is consistent with traditional verbal-performance classification of subtest scores, though the patterns are compatible with observed strengths and weaknesses of savant functioning documented in the literature (i.e. verbal/conceptual weaknesses and perceptual strengths).

Tasks requiring successive or sequential processing (digit span, coding, and arithmetic) distinguished prodigious from talented subgroups, though sequential processing ability did not differentially distinguish the type of skill (i.e. music, art, mathematics, etc.) manifested by the subject. Young concluded that although strengths in modes of processing may underlie *development* of a skill, they do not influence *type* of skill developed.

The Similarities subtest, which, in the normal population loads on the Verbal Comprehension factor, was aligned more clearly with the Perceptual Organization factor for Young's savants. Based on these findings, Young proposed that the subjects in her study approached the Similarities subtest using a different mode of information processing than would be expected among the normal population.

Like savants, people with Williams Syndrome display cognitive profiles with peaks and valleys of strengths and weaknesses and unusual modes of processing information. We turn now to explore the unique talents of this population.

### Williams Syndrome

Williams Syndrome, a genetically based disorder manifesting in generalized mild-to-moderate mental

<sup>2</sup> In a discussion of prodigies and creativity, Morelock & Feldman (1999) introduce a classificatory system for levels of creativity: 'Low C Creativity' refers to "Everyday occurrences of creativity exemplified by original transformations in small products, thoughts or expressions. "Middle C Creativity" refers to "Creative products appreciated in terms of interpretive skill, mastery of technical forms, distinctive style, and success in achieving a technical, practical, commercial or academic goal". "High C Creativity/Genius" refers to "Unique reorganizations of knowledge resulting in substantial new contributions to bodies of knowledge". (Morelock & Feldman, 1999, p. 449). According to this system, most savant-generated creativity would be designated as 'Low C Creativity'.

retardation punctuated with corresponding peaks and valleys of specific abilities, is estimated to occur in 1 out of 20,000 births. It was first identified in 1961 by the New Zealand cardiologist, J. C. P. Williams. Williams had examined a number of young children with pixie-like facial features (e.g. a turned up nose and a small chin) and noted that all had similar heart problems and other medical symptoms as well as cognitive impairments. In a recent video,<sup>3</sup> the neurologist Oliver Sacks, observing that people with Williams Syndrome were “a highly musical species”, commented that he chose to refer to them as “Williams People”, adding that they had “an identity of their own, which is different”. The term ‘Williams people’ has subsequently made its way into general parlance, even being adopted by the Board of the Williams Syndrome Foundation, a major advocacy group for people with the disorder (Lenhoff, 1998)

Because Williams people lack a group of specific genes from one of their chromosomes (a ‘micro-deletion’), they share a range of similar physical and behavioral characteristics as well as cognitive impairments. In addition, they share a number of remarkable abilities (Lenhoff, 1998).

IQs of people with Williams Syndrome range from 40 to 100 (mean, ~60), accompanied by commensurate impairments in spatial, quantitative and reasoning abilities (Levitin & Bellugi, 1998). Most Williams people fail Piagetian tests (Piaget, 1963) for conservation of number, space, substance, weight, and quantity (Bellugi, Klima & Wang, 1996). In contrast, they exhibit better face processing and larger vocabularies than would be expected given their cognitive deficits. Typically talking fluidly and with feeling, they employ complex syntactic structures and a surprisingly large and unusual vocabulary (Bellugi, Wang & Jernigan, 1994). As a matter of fact, Williams adolescents show a *proclivity* for unusual words, typically matching correctly with a picture such words as ‘canine’, ‘abrasive’, and ‘solemn’. In a task requiring subjects to name all the animals they could think of in a minute, adolescent and adult subjects included choices such as ‘yak’, ‘Chihuahua’, ‘ibex’, ‘condor’, ‘vulture’, ‘unicorn’, and ‘saber-tooth tiger’, far more often than controls matched for mental age (Bellugi et al., 1996). Based on such findings, researchers conclude that unusual word knowledge, processing and choice is characteristic of adolescent and adult Williams Syndrome subjects.

Williams people are characteristically highly sociable. They typically converse with anyone, are generally polite, and have learned a number of complex social

mores to the extent that they may be able to carry on a conversation for a long time without being suspected as mentally retarded (Levitin & Bellugi, 1998).

Williams people also exhibit a heightened auditory awareness. Levitin & Bellugi (1998) dubbed this condition ‘soundscape sensitivity’ (see Schafer, 1969) to characterize their ability to differentiate *quality* of sounds and classify them on the basis of timbre. Associated with this heightened sensitivity to sound is a strong attraction to and often a talent for music. They also commonly exhibit ‘hyperacusis’—unusual sensitivity to noise with distress and discomfort or pain at levels of sound not causing discomfort in normal individuals (A. Don, personal communication, December 20, 1999).<sup>4</sup>

The above sections provided an introductory overview of what is known about prodigies, savants and Williams people. The following section examines more closely their comparative functioning in the domain of music.

### Music

As was noted before, in addition to being a talent domain for many people with Williams Syndrome, music is the domain in which the largest number of both prodigies and savants are found. It is also the only domain in which there has actually been some detailed, though limited, systematic research comparing and contrasting prodigy and savant performance (Miller, 1989). We turn now to consider some of that research.

#### *Case Study of A Musical Savant*

Miller (1989) conducted a case study of Eddie, a musical savant pianist, who was 5 years old at the time of first contact. At the time Miller first saw the 5-year-old savant, the child had received no formal music lessons and there was no piano in the home. There was no history of a special musical talent in the family, and none of the other members of the family played an instrument. Miller’s longitudinal study spanned a 4-year period during which Eddie, at the age of 6, began taking formal music lessons. This allowed Miller to observe the savant’s progress during the period of the formal lessons as well as to devise research tasks to assess Eddie’s natural acoustical and musical skills.

The researcher gained a more complete picture of Eddie’s musical abilities by exploring the literature on musical savants and by selecting three groups of diverse musically talented living subjects with whom to compare Eddie’s abilities. In addition, he compared Eddie’s musical skills with those of the musical prodigy Erwin Nyiregyhazi, documented in Revesz’s (1925) case study. Following is a synopsis of Miller’s impressions and findings.

<sup>3</sup> The referenced video, made by the Dutch American subsidiary, EO Productions, Inc. (Mons, Wilmowski & Detweiler, 1996), is entitled *Williams Syndrome: A Highly Musical Species*. It has earned seven national film festival awards in the USA.

<sup>4</sup> Dr. Audrey Don is a Postdoctoral Fellow in pediatric neuropsychology with the Department of Developmental Pediatrics at the Children’s Seashore House, Children’s Hospital of Philadelphia.

*Researcher meets savant: first impressions.* Miller describes his first encounter with Eddie as unexpected and dramatic, admitting that he was skeptical about this severely handicapped 5-year-old child who was reported to play the piano surprisingly well. Eddie presented as “a very fragile child, bony thin and small for his age” whose motor delay was apparent in his hesitant, splay-footed walking” (Miller, 1989, p. 1). Eddie’s speech was almost exclusively echolalic, except for a few conversational clichés such as “How are you?,” “I’m fine,” and “Good-bye.”

Nevertheless, when Eddie’s teacher mentioned the word ‘piano’, the child smiled excitedly and he turned to the room containing the piano, needing no prompting to exhibit his talent. At the piano, Eddie’s hands found the keys easily and he started to play some melodious chords, “his head tilted back, staring through his thick glasses at the ceiling with an intent expression on his face” (Miller, 1989, p. 2).

Eddie’s first recital for Miller consisted of a rendition of the Christmas carol, ‘Silent Night’. The melody was well articulated, with an appropriate tempo, and a nice rolling broken chord figure in the bass. “Eddie’s hands, which had difficulty holding a pencil, were clearly at home on the keyboard” (Miller, 1989, p.2).

On Miller’s second visit, he tested the range of Eddie’s musical sensitivity. Realizing that technical facility across all major and minor keys on the piano is generally achieved only with considerable instruction and practice, Miller questioned how well Eddie could follow a simple melody through a series of transpositions on the keyboard. Was the child’s facility limited to a few common keys, or would the particular key of the piece prove irrelevant?

Miller engaged Eddie in a musical ‘Game’ in which the child was required to repeat a simple melody exactly as it had initially been played by the researcher. Through this little experiment, he discovered that Eddie’s talent was not limited to a few, well-practiced patterns of movement on the keyboard. The boy had an impressive sensitivity to the tonal structure of a melody line, and he could follow that melody wherever it appeared in the pitch range represented by a piano keyboard. In addition, he was capable of improvisation—he could take a melodic line and produce variations consistent with the conventions of musical composition.

Such skill dramatically contrasts with musical ability of average 5-year-olds. Normally, a 5-year-old could be expected to have, at best, a slim grasp of interval relationships in even a simple melody (Bartlett & Dowling, 1980); and their spontaneous songs often wander from one tonal center to another, with little sense of an overall tonal structure (Hargreaves, 1986). Not only did Eddie demonstrate a much better grasp of the structure of music than would be expected for a child his age, but his understanding was manifested

naturally and concretely in his playing. Miller comments: “The piano seemed an extension of Eddie’s body, and his fingers effortlessly explored its range of sounds as soon as he came in contact with its keyboard” (Miller, 1989, p.3).

Eddie’s extraordinary musical ability led Miller to wonder what it was, exactly, that Eddie knew about music. Of what was this incredible musical intelligence—so disparate with the rest of Eddie’s abilities—comprised? The results of his case study revealed some answers to these questions. Below we outline some of Miller’s major findings; as they are reported, we will discuss their possible implications for our understanding of music prodigies, as well. This comparison and contrast will be followed by a short explication of talent in Williams people, outlined according to some of the same kinds of categorical topics as Miller explored with his study of savants.

#### *Miller’s Findings*

*Absolute pitch: definition and incidence.* *Absolute pitch* is generally defined as ‘the ability to name the note of any tone heard without either seeing it played or the benefit of a reference note’ (Miller, 1989, p. 15). *Extended absolute pitch* means that the ability extends over the whole musical scale and is independent of the instrument used. Miller reported extended absolute pitch to be present in all well-documented cases of musical savants. A 100% incidence within this seems even more extraordinary when compared with the incidence in the general population, where it is estimated to be less than one-hundredth of 1% (Bachem, 1955).

For Eddie, absolute pitch was separate from knowledge of the verbal names of the notes: he was able to match tones to their equivalent piano notes before he had ever been taught the note names. Miller deduced that this would apply for other savants, as well, since their generally restricted language abilities made verbal association an unlikely means of learning. Once Eddie learned the names of the notes, however, he delighted in pointing out the ‘names’ of sounds. A passing police car’s siren was F and G: while the bell in an elevator was identified as A#.

*Exploring absolute pitch further.* Miller tested Eddie and his comparison subjects on the identification of single tones and chord groups. Only the subjects who, like Eddie, possessed secure absolute pitch gave quick, accurate and confident judgments across the tasks presented—even when the chords contained dissonant notes.

Other subjects were able to use ‘relative pitch’ in identifying notes. That is, after a reference tone was sounded, they were able to recognize a second tone as identical, lower or higher, and perhaps estimate a proportionate distance by which the two presented notes differed. Even so, individuals with relative pitch

characteristically identified notes more slowly, considering a number of options before settling on a 'guess'.

As Miller's absolute pitch subjects varied considerably in age, musical training, and level of general intelligence, he concluded that the consistency of their results argued for absolute pitch as a distinctive skill with important consequences for music perception.

*Absolute pitch and musical syntax.* Miller proposed that absolute pitch and the intuitive link it represents between chroma (note name) and tonal frequency suggests the faculty may provide a foundation for the development of higher order structures and a basis for higher order pattern extraction. The beginning musician must learn to map or represent musical notes in a reliable way before he can construct higher order groups in music. The savant, according to Miller, has a ready means of doing so by virtue of the 'internal standard' he possesses for each note of the chromatic scale, i.e. the faculty of absolute pitch.

Miller suggests that the concept of parallel distributed processing (PDP) (Rumelhart & McClelland, 1986) may prove helpful in explaining how a higher order musical structure or pattern emerges. PDP models characterize information processing as involving the activation of specific groups of units corresponding to aspects of information present in the stimulus array. In music performance, it might work like this: the presence of chroma information (e.g. hearing the note 'C') activates several candidate key signatures—keys in which the note 'C' naturally occurs, such as C, G, or F Major. At the same time, it inhibits orientation towards other keys in which 'C' does not appear—such as D Major. This restricted range of key signatures affects subsequent patterns of activation at the chroma level. Chroma values consistent with the suggested key are augmented; whereas, those inconsistent with the key are inhibited. Thus, by its frequency, a note not only specifies central categories (chroma), but it also suggests another series of relations among sounds in terms of candidate keys for the musical piece in question. The 'inevitability' of various frequency-chroma-scale links represents a pathway by which a young musician with a particularly good sense of chroma identification could start establishing a more complex system for extracting patterns in music—a hierarchical representation of the stimulus structure of music.

Eddie's musical performance, as well as that of other savants, does indeed reflect regularities and consistencies related to the structural rules embedded in musical composition. There is little evidence, however, that musical or other types of savants consciously apply a structured set of rules to their material of interest (Hermelin & O'Connor, 1986; Howe & Smith, 1988; Miller, 1989); and the speed of savant response seems to preclude the notion of some complex formal

rule structure. Miller concludes that, like the child whose language expression and comprehension reflects the rules of syntax, so the musical savant's performance shows 'musical syntax' rule use. In neither case is conscious knowledge of the system of rules necessary.

*Absolute pitch and the prodigy.* No one has completed a review of historically documented music prodigies to determine just what percentage has shown absolute pitch. Nevertheless, accounts of various prodigies' extraordinary faculties of absolute pitch do appear every now and then.

Revesz's prodigy, Erwin Nyiregyhazi, exhibited absolute pitch. Revesz noted the speed and confidence with which the prodigy identified the component notes of complex chords:

Erwin's verdicts were given immediately without reflection and with perfect confidence. One characteristic of the boy's performance was that during these experiments he always smiled in a superior manner, the tasks put before him being so easy to him that he did not take them seriously (Revesz, 1925, p. 75).

An article appearing in the *New York Times Magazine* (Winn, 1979, December 23) included a fascinating account by pianist Lorin Hollander of how his father first discovered that Hollander was a prodigy . . .

When I was 3½, I went with my father to a rehearsal and heard them play a Haydn quartet. I was profoundly moved by the music. When I came home, I wanted somehow to put down what I had heard. I found some drawing paper and began to draw spirals. My father asked me what I was doing, and I began to sing him back the piece, which I remembered perfectly, and told him that I was trying to write it down. My father said, "No, you silly boy, we already have a way of writing music", and he brought out the score to show me. I fell into the music; that's the only way to describe it. Within four minutes I knew the notes, the clefs, everything. A car horn sounded outside and, just for fun, my father asked me what note it was. I immediately answered, 'F sharp'. He took a spoon and clinked a glass, 'B flat', I told him. Then he and my mother realized they had a prodigy on their hands and they started to run around to people to find out what to do' (Winn, 1979, December 23, p. 37).

Then, of course, there is Mozart. Of this legendary child prodigy, Marshall (1991) comments that his musical memory was perhaps the most formidable in history, going far beyond absolute pitch. It included the ability to hear and remember entire compositions—motets, concertos, even operas—and subsequently write them down. A letter from Mozart's father, Leopold, to his wife from Rome in April, 1770, when Mozart was 14 years old attests to this:

You have often heard of the famous Miserere in Rome, which is so greatly prized that the performers in the chapel are forbidden on pain of excommunication to take away a single part of it, to copy it or to give it to anyone. *But we have it already.* Wolfgang has written it down and we would have sent it to Salzburg in this letter, if it were not necessary for us to be there to perform it. But the manner of its performance contributes more to its effect than the composition itself. So we shall bring it home with us. Moreover, as it is one of the secrets of Rome, we do not wish to let it fall into other hands, *so that we shall not incur the censure of the Church now or later* (Marshall, 1991, p. 5).

It may well be that absolute pitch operates in prodigies as Miller suggests it does in savants—to provide a foundation for the structure and higher level abstraction of patterns in music. Given Mozart's extraordinary acoustical memory, could we expect him to recall equally well some extended set of random notes or sounds? While there are no specific data on Mozart addressing this question, Miller offers some findings that may be relevant.

*Memory in musical savants.* Miller (1989) presented a series of chord, melody, and rhythm tasks to Eddie and his comparison subjects to assess short-term memory capacities. The findings suggested that savants did extremely well when the task required retention of harmonic information. When tasks involved tonal material presented sequentially, or 'melody-like' information, they also did quite well, though their performance was not quite so exceptional.

Miller found savant musical memory was enhanced by increased structure or organization in the material to be remembered. The more the stimulus array was composed of 'just notes' (e.g. unconventional chords, random tones, or irregular intervals), the less remarkable savant performance was. Miller concludes that savant performance resembles the selective memory found among those with expert knowledge in a domain: "... the savant's memory excels most when the more meaningful or structured aspects of music are present. In each case, it seems most parsimonious to assume that the excellence of immediate memory reflects a complex and well-structured representation of the domain in long-term" (Miller, 1989, p. 112). Tasks requiring reproduction of portions of intact compositions suggested that this response to musical structure extended to a sensitivity to the implicit rules governing music composition in Western culture. For example, notes consistent with the underlying scale of a piece were more likely to be reproduced accurately.

*Memory in the music prodigy.* Revesz (1925) also assessed the memory of his young prodigy, establishing that Erwin easily memorized melodious pieces with simple harmony and had no difficulty remembering a

large number of operatic arias, having learned them in a very short time. Revesz noted that as a rule, however, only the melodies without the harmonies were reproduced without error. This is interestingly to contrast to Eddie's superior performance in reproducing the harmonic dimensions of music as opposed to the melodic. In considering Revesz's findings, however, Miller (1989) states that in view of Erwin's proven ability to render complex chords with great precision, this conclusion about more extended musical excerpts may reflect an attentional bias or preference (Eddie loved operative arias) rather than a particular performance limitation.

Erwin, like Eddie, found unconventional musical excerpts more of a challenge. Revesz notes: "In the case of musical pieces of a strange character, such as melodies with complicated accompaniment and peculiar harmonies, his memory did not prove itself equal to the task" (Revesz, 1925, p. 90). Whether this would have proven to be the case as well with Mozart, one cannot tell for sure. But one might speculate that even Mozart's phenomenal musical memory may have been facilitated by the presence of conventional structure in whatever material he was memorizing at the moment.

*Sight reading skills.* Unlike Eddie, Erwin's extraordinary talent included a prodigious acquisition of sight reading capabilities. By the age of 6, Erwin already preferred optical exposure to the music rather than just hearing it; and he obviously benefited from seeing the written score while attempting to master a musical piece. Interestingly, while 'reading' a new score without benefit of hearing the music, Erwin would hum the melody to himself while moving his fingers as if he were playing the theme on the piano, thereby fixing the theme in his memory by motor means. Revesz noted that the child appeared to be trying to imprint the treble on his memory by singing, and the lower parts by the action of playing.

*Language in the savant.* Only two characteristics are possessed by *all* musical savants. The first is extended absolute pitch. The second is some significant degree of language disability (Miller, 1989). The language deficit appearing in musical savants has a specific form. Generally, savants show considerable facility in the phonetic (sounds of speech) and syntactic (rules for combining words into phrases and sentences) aspects of language, while manifesting severe deficits in semantics (the acquisition of words and the meanings associated with them) and pragmatics (using language to express one's intentions and for getting things done in the world). Echolalic speech, such as that manifested by Eddie, appears in the great majority of cases.

Miller argues that echolalia implies that the savant has considerable sensitivity to his or her surrounding language as a system of sounds. Additionally, there is

some knowledge as to how these sounds are combined to produce extended sequences. What is missing is manifested awareness of the communicative function of language and its role in sharing meanings about environmental events and objects (Sigman & Mundy, 1987). The presence of this specific pattern of partial language ability tells us that development of extraordinary musical abilities in the savant does not require the *absence* of ‘competing’ language. In fact, Miller continues, the most gifted musical savants are *not* mute.

Miller (1989) provides a brief recapitulation of Eddie’s language development, noting that at age 5<sup>1</sup>/<sub>2</sub>, his language was monosyllabic and/or echolalic. Conversations were generally one-way, with Miller reminding Eddie to listen while a piece was played, informing him of the names of the pieces, and responding with verbal approval to Eddie’s playing. Over time, Eddie started reliably repeating the names of requested tunes, although often not with the appropriate melody. Miller observed that the first notes of a song were more reliable cues for Eddie than was the song’s title. With the advent of formal music lessons, Eddie gradually began to name notes and additional tunes; he also started commenting on pieces and including simple requests or instructions to the teacher during the lessons.

*Language in Erwin, the prodigy.* The semantic, pragmatic, and conceptual impoverishment of Eddie’s savant mode of speech contrasts dramatically with the pragmatically astute, conceptually rich, and emotionally colored language of Erwin, the prodigy. Revesz observed that the child often asked if what he was about to say would get “into the book”, for in this case, Erwin noted, “I want to express myself correctly, and you must pay great attention to me; for a single wrongly-chosen word may alter the meaning of the whole thing” (Revesz, 1925, p. 42).

Revesz also noted that Erwin, unlike most musicians or artists, grasped with absolute precision questions asked of him about his own experiences or processes of consciousness during creative activity or interpretation, and responded with incredible insight. For example, when Revesz asked him whether during the whole time he was composing a piece, he maintained the same state of feeling, Erwin replied that he did so as far as possible, adding “When composing, one must not always give way to one’s *heart*, the head must also be consulted. Often it is necessary that the heart should be silenced, pushed into the background, otherwise the composition will become weak” (Revesz, 1925, p. 45).

*A few final notes on the piano.* Overwhelmingly, the piano proves to be the instrument of musical savants. Why? Miller (1989) points out that the piano keyboard maps its sound producing qualities onto the musical

culture in a direct fashion. It contains, in effect, the alphabet of the musical language laid out in a coherent spatial organization. Octaves and various harmonies appear in a recurring, spatial pattern, making it relatively easy to explore sound combinations in both direct and extensive ways. Piano keys release pleasing tones readily—without the application of subtle bowing or fingering techniques such as are needed for string or wind instruments. Finally, the piano is a popular instrument—one which is more commonly available to the young child.

### The Musical Talents of Williams People

From music therapists, private music teachers, and parents has come mounting anecdotal evidence regarding the innate musical abilities of many people with Williams Syndrome (Lenhoff, 1998).<sup>5</sup> In addition, there is a small, but growing formal literature investigating the musical abilities of this population. What has been investigated so far allows us to compile some findings associated with the areas explored by Miller in his study comparing savant and prodigious musical performance.

*Absolute pitch.* Preliminary findings from research funded by the National Science Foundation at the University of California, Irvine, suggest that the incidence of absolute pitch in the Williams populations is higher than it is in the average population—perhaps as much as 5 times higher (H. M. Lenhoff, personal communication, July 9, 1999).<sup>6</sup>

*Memory in Williams musicians.* Some Williams musicians are able to retain complex music (some in a variety of languages), including both the words of many verses of long ballads and the melodies, for periods of years (Lenhoff, 1998). Those who learn to

<sup>5</sup> The reader is cautioned against presuming that all people with Williams Syndrome are musical. While unusual attraction to music is widespread Williams people and musical talent is common, the degree of talent across individuals varies widely. Furthermore, the Williams Syndrome Association (a membership organization representing nearly 4,000 families in the USA) often hears from parents who say their child is *not* musical. To date, there is no published study of the incidence and degree of musicality in persons with Williams Syndrome (S. E. Libera, personal communication, December 20, 1999). (Dr. Sharon E. Libera is Co-Founder and Coordinator of the Williams Syndrome Music and Arts Camp at Belvoir Terrace in Lenox, Massachusetts).

<sup>6</sup> Dr. Howard M. Lenhoff is Professor (Emeritus) in the Department of Developmental and Cell Biology, University of California, Irvine. He is co-founder of the Williams Syndrome Music and Arts Camp in Lenox, Massachusetts, and is currently Executive Vice-President of the Williams Syndrome Foundation. He is the principal investigator of a National Science Foundation grant to study music cognition in Williams Syndrome, and is father of the Williams musician, Gloria Lenhoff.

sing in foreign languages show near perfect accents. They have a sensitive ear and rapidly learn melody and lyrics simply by hearing a piece a number of times. Lenhoff (1998) notes that usually once they learn a piece, they rarely forget it.<sup>7</sup>

*Sight reading.* Most Williams people cannot read musical notation. Although some may be capable of doing so, and some can sight read, many feel more comfortable returning to learning by ear and playing without reading the notes (Lenhoff, 1998). Lenhoff observes that the cognitive processing of information involved in reading musical notes appears to interfere with their desire to produce music. On the other hand, some Williams musicians have been known to learn to sight read and at least one known Williams musician prefers sight reading to playing by ear (S. E. Libera, personal communication, December 20, 1999).

*Language.* The surprising facility with language that many Williams people have, given their general cognitive deficits, has already been mentioned. Most likely related to their sensitivity to nuances of sound, Williams vocalists are also generally good at mastering music in foreign languages. Lenhoff (1998) writes of his 43-year-old daughter, Gloria, who, with a trained voice has performed operatic and other kinds of music for a wide variety of audiences, is the most highly accomplished Williams musician known today<sup>8</sup>:

Gloria, like many Williams people, has perfect pitch. She also has a lovely lyric soprano voice, great skill at playing the large piano accordion, and a repertoire

of over 2000 pieces in 25 languages. She does not read musical notation and only recently has been able to identify the white notes on the keyboard. (Lenhoff, 1998, p. 16).

Levitin and Bellugi (1998) wrote of one Williams musician who is a prolific creator of songs. When asked by an experimenter to write a song about the breakfast cereal, he spontaneously composed one on the piano, complete with verse, chorus, and rhyming lyrics!

Though fluidly creative with language in speech and lyrics in song, the linguistic products of Williams people typically have a naïve quality about them. Given their documented conceptual deficits, it is intriguing that many Williams people use metaphor and analogy in describing their experience (A. Don, personal communication, December 20, 1999). One Williams musician, 24-year-old pianist Christian Lawson, exuded “Music lights a fire in me and I feel it go right through my system! It’s like I’m in paradise”. (Scheiber, 1998, p. 1F). A second, Meghan Finn, when asked by her teacher what music was to her, described it as ‘soup’—because you drank it down, it made you feel all warm inside, it was nourishing, and she had a really big spoon. (Mons, Wilmowski & Detweiler, 1996)

*Rhythmicity and audiation.* Levitin & Bellugi (1998) investigated the rhythmic abilities of Williams people. The researchers, noting that Piagetian theory stated that, across domains, conservation is required for activities involving temporal order, seriation, and rhythmic organization, deduced that rhythmic abilities ought to be impaired in children who have not yet reached the conservation stage. Indeed, in former research with normal children (Serafine, 1979) metric conservation in normal children was highly correlated with the standard (non-musical) Piagetian conservation tasks. In addition, Miller (1989) found no evidence for rhythmic abilities in musical savants and argued that their musical skills were focused in melodic and harmonic domains.

Using a graduated series of one- and two-measure rhythmic patterns clapped by the experimenter, the investigators engaged their subjects in an ‘echo clapping’ or ‘rhythm repetitions task’ (Levitin & Bellugi, 1998). The investigators noted that while not instructed to do so, all the subjects tended to look the experimenter in the eye (rather than watching the experimenter’s hands) during the demonstration of the reference rhythm. In addition, in nearly every trial, the subjects clapped back the demonstrations immediately in perfect time, without missing a beat, as if their response formed part of the same rhythmic sequence. When Williams subjects failed to reproduce the presented rhythm perfectly, the rhythm they did clap bore a clear musical relationship to the referent—as

<sup>7</sup> Investigators at the University of Connecticut found some preliminary evidence that music can serve a memory and comprehension-enhancing function in Williams people attempting to master quantitative skills. (R. M. Schader, personal communication, June 18, 1999). (Dr. Robin M. Schader was Program Co-Director of the 1998 *Music and Minds* research initiative co-sponsored by the School of Education, the Music Department, and the NEAG Center of Gifted & Talented Education at the University of Connecticut).

<sup>8</sup> In 1988, an award-winning PBS documentary, *Bravo Gloria*, was produced describing Gloria Lenhoff’s outstanding musical talents and telling about her life (Maas & Alda, 1988). In response to that documentary, Gloria’s parents received a number of letters and phone calls suggesting that she had Williams Syndrome. Up until that point in time, they had never heard of the disorder (Lenhoff, 1998). The film also piqued the interest of a number of parents in training their Williams children in music. Lenhoff notes: “We often wondered if had we learned when Gloria was a child that she had WS, would we have been discouraged by counselors and teachers and not given her a good musical education?” (Lenhoff, 1998, p. 16.). As of December, 1999, Gloria Lenhoff sings in 26 languages, the most recently acquired being Arabic which, her father notes, “is full of quarter tones” (H. M. Lenhoff, personal communication, December 20, 1999).

though the subject were creating a musically logical completion to the rhythm provided. Furthermore, in contrast to the Piagetian theoretical prediction, all of the experimental subjects demonstrated *conservation of musical time*. If a subject clapped a greater or lesser number of musical notes, in most cases, the subject altered the length of the notes to take up the same amount of metrical time as the exemplar. The investigators concluded that subjects with Williams Syndrome show evidence for a quality that they called *rhythmicity*, or *rhythmic musicality*.

Williams musicians' highly developed, creative sense of rhythm contrasts with savant talent, which Miller found to be confined to melody and harmony. One could argue that Williams people's ability to transform rhythmic patterns while conserving musical time is reminiscent of the playful creativity of Mozart, who was given to making innumerable changes and transformations in speech, writing, and music, while skillfully conserving underlying patterns (Morelock & Feldman, 1999).

In another study, Don (1997) investigated audiation and rhythmic ability in Williams people, testing 19 individuals with Williams Syndrome using the tonal and rhythm subtests of *Gordon's Primary Measures of Music Audiation* (1980). Audiation, according to Gordon, "takes place when one hears music through recall or creativity, the sound not being physically present" (p. 107). Don compared her Williams Syndrome group with a comparison group of 19 normal children, equivalent in terms of receptive vocabulary age (8 yrs. 1 mo.) as measured by the Peabody Picture Vocabulary Test-Revised (PPVT-R). She found the level of audiation exhibited by her subjects to be commensurate with their preserved language skills rather than on a par with their levels of general cognitive ability (average receptive vocabulary score on the PPVT-R for the Williams group was 78; average full scale IQ score on the WISC-III was 53). Don concluded that, generally, musical skills among the population of Williams people are a *relative strength* rather than a 'savant skill', although she noted that some Williams people's musical abilities are more extreme and savant-like (A. Don, personal communication, December 20, 1999). Where the Williams children *did* stand out as different was in their *emotional response* to the music.

*Affect*. Given the 'flat effect' so often cited in the savant literature, the affective response of Williams people to music is of particular interest. Don (1997) used a *Child Music Interest Interview* and a *Parent Language and Music Questionnaire* to compare her groups in terms of their interest in music and their auditory characteristics. The groups differed neither in their musical background and environment nor in their history of creating music. However, emotional responsiveness stood out in the Williams group. Of the Williams

group, 100% reported that music could make them feel happy, while 84% of the comparison group responded likewise. The 'negative' response of one Williams child had to be recoded as positive when he explained that music did not make him feel happy *because it made him feel more than happy*. Whereas 79% of the Williams Group reported that music could make them feel sad, only 47% of the comparison group made a comparable response.

Perhaps most striking are the spontaneous reports from the parents of the Williams children. Some noted that when their children were very young, they cried inconsolably when exposed to slow, sad music. One child screamed and refused to listen to a lullaby composed specifically for her (A. Don, personal communication, December 20, 1999).

*Choice of instrument*. Unlike savants, who overwhelmingly gravitate to the piano, Williams musicians choose a variety of instruments, musical genres, and styles of performance. These choices appear to be much more a matter of individual affinity (S. E. Libera, personal communication, July 1, 1999), though motor problems commonly associated with the disorder also play a role in determining which instruments remain viable options (H. M. Lenhoff, personal communication, December 20, 1999).<sup>9</sup>

Having explored what is known about the configurations of talent reflected by prodigy, savant and Williams populations, we are left with more questions than answers. This is to be expected, considering the fledgling state of research. Nevertheless, the following section considers what we have learned and where we might go next in juxtaposing the extremes.

### Juxtaposing the Extremes

Accumulated research exploring savants, prodigies and Williams people appears promising. To date, no studies compare the abilities of Williams people with those of savants. Nevertheless, findings from independent investigations suggest that such a study would be worthwhile. While overall levels of general cognitive ability in these two populations are similar, their profiles of specific abilities show intriguing disparities and commonalities. Savants are deficient in language, while Williams people are particularly facile. While prosodic features of speech may be absent or disturbed in savants (O'Connell, 1974; Miller, 1989), Williams people use affective prosody far more frequently than even normal children (Bellugi et al., 1996).

A similarity between the two populations may be the incidence of absolute pitch; it appears that the majority

<sup>9</sup> Howard Lenhoff cites voice, keyboard and drums as the most favored instruments among Williams musicians, noting that these are also the main instruments taught at the Williams Syndrome Music and Arts Camp at Belvoir Terrace in Lenox, Massachusetts. However, various Williams musicians have mastered trumpet, clarinet, violin, guitar, or accordion.

of savants (Judd, 1988; Miller, 1989) and, as mentioned previously, possibly a large proportion of Williams people have absolute pitch. A recent investigation (Schlaug, Jancke, Huang & Steinmetz, 1995) found individuals with absolute pitch to have a larger planum temporale in the left hemisphere. The publication of these results in the journal *Science* led neurologist Oliver Sacks (1995b) to suggest that the exaggerated leftward asymmetry of the planum temporale in musicians with perfect pitch may also underlie perfect pitch as a 'savant talent' in disabled persons. In response to Sack's speculations, Hickok, Bellugi & Jones (1995) sent a letter to the editor of the journal, reporting that they had used magnetic resonance images (MRI) to analyze the planum temporale in Williams Syndrome subjects. They found the planum temporale asymmetry for Williams subjects to be comparable to that of the group of musicians studied by the former investigators. Three of the four Williams subjects had greater asymmetry than that of the musicians, but less than that of musicians with perfect pitch. In addition, Williams subjects did not differ from normal subjects in planum temporale surface area despite the overall reduction of cerebral volume previously reported in subjects with Williams Syndrome (Jernigan, Bellugi, Sowell, Doherty & Hesselink, 1993).

The investigators cautioned, however, that since individuals with Williams Syndrome typically possess exceptional language abilities relative to other cognitive domains (and despite mental retardation), planum temporale asymmetry may be related to linguistic abilities rather than, or as well as, musical abilities.

While linguistic and musical abilities may be highly confounded in both Williams people and musical prodigies, they may be less so in musical savants. We might speculate that MRI research analyzing the planum temporale in musical savants may shed light on whether this focal area of the brain is specifically related to musical abilities rather than linguistic abilities. Or perhaps the question pertaining to the relationship between linguistic and musical abilities may prove more complex, as Morelock's (1995; Morelock & Feldman, in progress) studies of child writers seems to suggest.<sup>10</sup> Brain imaging techniques

may provide clues as to whether and how certain writing, such as poetry, with its emphasis on rhythmic cadence and the sound of words, may be linked in the brain to music production in a way that prose is not.

The connection between linguistic abilities and musical creativity is a related area that may also be explored through comparative studies of savants and Williams subjects. Miller's (1989) report of the savant whose enhanced language development coincided with an emerging ability to compose music is especially intriguing when viewed beside the fluidity of language and capacity for melodic and rhythmic creativity characterizing people with Williams Syndrome. What does this have in common, if anything, with the playful verbal creativity that Mozart exhibited alongside his extraordinarily creative musical achievements (Morelock & Feldman, 1999)? This is another question whose time has come.

Perhaps the purest essence of domain-specific talent is the ability to holistically intuit the syntactic core of rules and regularities lying at the heart of a domain of knowledge: the pattern of relationships between numbers, the pattern of tones in a musical scale, the pattern of images in the visual world, the pattern of words in a language (Morelock & Feldman, 1993). However, evidence has accrued that even in savants, general cognitive ability plays a role in degree of precocity (Young, 1995; Young & Nettelbeck, 1995; Nettelbeck & Young, 1996) as well as in the emergence of aesthetic qualities (O'Connor & Hermelin, 1987). Young's (1995) studies of the families of savants echoes Feldman's (Feldman with Goldsmith, 1991) and Morelock's (1995) findings in families of prodigies, where facilitative environments and supportive hereditary influences combine to encourage the flourishing of talent. A comparable exploration into the families of extraordinary Williams musicians would be of interest here. Might we find among the families of the more talented Williams musicians a suggestion of underlying biological predisposition toward high level ability and an overt valuing of achievement much like that which Young (1995) found in her families of savants? Longitudinal case studies tracing development over time and aiming for a comprehensive contextual understanding are needed (e.g. Feldman, 1980, Feldman with Goldsmith, 1991; Morelock, 1995, 2000).

Given what we have learned from the combination of case studies and empirical investigations, we are

<sup>10</sup> In two case studies of highly talented child writers, Morelock documented some intriguing parallel differences in terms of their creative processes as they wrote poetry and prose. Both children reported that poetry "came to them" suddenly, unbidden and fully-formed. One of the girls reported that when poems first started "coming to her", they were always accompanied by music. She would hear in her mind a voice singing the words of the poem. Eventually, the voice became her own, and over time, the music stopped accompanying the poetry. In contrast, for both girls, prose evolved out of play. Both children independently created a process in which they set up figures and/or dolls and proceeded to allow them to play out a scenario that the

<sup>10</sup> Continued  
children narrated. The ensuing drama, upon its completion, got transformed into a written story. Morelock speculates that the creation of poetry requires different brain functioning, perhaps more akin to that required to create music and relying in a different way or to a different extent upon right brain processes.

beginning to see the wealth of knowledge that we can glean from comparison and contrast of extreme talent in its diverse forms exhibited by individuals with a variety of genetic and neurological substrates. We look forward to what investigators will find through continued explorations of the kind we have considered here.

### Acknowledgements

The authors wish to express their appreciation to Professor Howard M. Lenhoff, Dr. Sharon E. Libera, Dr. Audrey Don and Dr. Robin M. Schader for freely sharing their knowledge and experience in the world of Williams people. To Professor Lenhoff and Dr. Libera go special thanks for reviewing the first draft of this paper and kindly offering invaluable comments and suggestions. Whatever shortcomings might be found in the final product are solely the responsibility of the authors.

# Addressing the Most Challenging Questions in Gifted Education and Psychology: A Role Best Suited to Longitudinal Research

Rena Subotnik<sup>1</sup> and Karen Arnold<sup>2</sup>

## Introduction

Fundamental challenges in the field of gifted education and psychology involve finding the right people and nurturing their gifts appropriately. Both aims require research that connects promise with attainment. Unique among research designs, longitudinal investigations, which collect information about the same individuals on multiple occasions over time, yield direct evidence about the conditions that lead to the fulfillment of talent. Repeated measures studies use a variety of quantitative and qualitative data, appear in a variety of social science disciplines, draw from a wide range of theoretical perspectives, and focus on both individual trajectories and group patterns.

The fields of gifted education and psychology have developed sufficiently over the decade to have elicited highly complex questions and concerns that require a comprehensive and long-term approach to problem solving and policy making. The continuing effects of all the variables we claim to be important to the study of gifted children and adolescents—programs, instructional strategies, mentoring, parenting styles, and innate qualities above and beyond IQ—are finally being addressed. As will be seen in the discussion that emerges from this chapter, the community of scholars that employ repeated measures methodology envision the need for more refined theoretical and design models to answer increasingly sophisticated questions about the development of giftedness and talent.

In the last edition of the *Handbook*, we provided readers with samples of classic longitudinal studies and a synthesis of the literature from the 1980s and early 1990s that were organized around issues of identification, sex differences, program effectiveness, definitions of success, and personality variables. In addition, the strengths and weaknesses of longitudinal research

methodology were delineated. We urged scholars to conduct more research on young children, to use more sophisticated, multi-cohort methodologies, and to focus more on domain specific talent development.

## Chapter Preview

Since 1993 a rich array of repeated measures studies have been conducted in countries around the world and published in English. We have organized the studies into categories and describe them briefly for readers. We then provide an analysis of the current literature in relation to our perspective of what is needed by the field. The final sections of the chapter provide a platform for presenting our views of the key issues in the field, and arguing that longitudinal data provide the most promising foundation for meaningful program design and policy making.

## Recent Longitudinal Research

New single cohort longitudinal studies and several ongoing larger projects have appeared in the literature since the first edition of the *International Handbook*. Our review of classic and contemporary longitudinal studies in that volume was organized around the themes of gifted identification, educational intervention, and domain specific talent. Interestingly, the literature since 1993 only partly overlaps with these a priori conceptual categories. A heuristic grouping of recent studies follows, beginning with edited collections of repeated measures research and continuing in order of the prevalence of each topic within the longitudinal literature.

## Collections of Longitudinal Studies

Collections of longitudinal studies provide relevant sources for assessing both longitudinal research findings and repeated measures methodology. Subotnik and Arnold edited a 1994 collection: *Beyond Terman*:

<sup>1</sup> Center for Gifted Education Policy, American Psychological Foundation, USA. E-mail: rena.subotnik@hunter.cuny.edu

<sup>2</sup> Boston College, USA.

*Contemporary Longitudinal Studies of Giftedness and Talent.* The editors discuss the advantages of repeated measures methodology for addressing the central issues of gifted education. The 16 studies in the book investigate the determinants of later academic and career achievement for different populations identified on the basis of early demonstrated accomplishments, on intelligence test and achievement test scores, and on inclusion in educational programs for the gifted. The editors analyzed the body of findings to enable researchers, policy makers, and practitioners to compare the long-term effects of different identification procedures. Important patterns across the collected studies were: (1) the close relationship between individual outcomes and identification criteria or educational program emphasis; (2) the continuing salience of gender as a mediating variable in talent development; and (3) the general methodological weakness of most contemporary longitudinal studies in the field.

Subotnik and Arnold also edited a special longitudinal research issue in the gifted journal, *Roepers Review* (1993, Volume 15, Number 3). In addition to several studies that appeared in *Beyond Terman*, the issue included some longitudinal projects on academic acceleration, academic achievement, and IQ test stability.

Two other collected works contain studies about gifted populations as well as relevant analyses of methodological issues across longitudinal investigations. The earliest of these is a collection of research on educated American women from various Twentieth Century birth cohorts, *Women's Lives Through Time: Educated American Women of the Twentieth Century* (Hulbert & Schuster, 1993). The focus of the volume is on the interplay of changing societal forces and the life paths of college-educated women. The book's 15 studies explore changing definitions of success for women, relationships between personal values and levels and domains of accomplishment, and the impact of historical and social forces on women's talent development. Second, a special issue of the *Journal of Creativity Research* (1999, Volume 12, Number 2) edited by Runco, presents several studies specifically devoted to giftedness and features longitudinal studies across the related field of creativity.

#### *Ongoing Major Studies*

Two ongoing, major longitudinal studies of gifted students warrant special mention in connection with this chapter's topic. (See chapters by study directors in this volume for comprehensive discussions of the projects.) In the United States, the Study of Mathematically Precocious Youth (SMPY) is approximately halfway through a planned 50-year multiple cohort investigation (Benbow, 1992; Lubinski & Benbow, 1995). Participants were identified at age 13 as high scorers on the mathematics portion of the Scholastic

Aptitude Test (SAT-M) normally taken by American secondary students for the purposes of university entrance. Currently, 4000 students from four cohorts have participated in three or four waves of data collection. In a recent published study, vocational interests derived from the Strong-Campbell interest inventory at age 13 were found to predict adult career profiles at age 28 (Lubinski, Benbow & Ryan, 1995). Insights into the career and life choices of participants have richly rewarded the educational community.

The Study of Mathematically Precocious Youth was the model for a mathematics talent search and educational program at the University of Hamburg. This German program has also yielded some follow-up studies that indicate positive effects of identification via mathematics tests in early adolescence and for a challenging enrichment program (Wagner & Zimmerman, 1986; Wiczerkowski, Wagner & Birx, 1987).

A second large sample, multi-cohort longitudinal study is underway in Germany. The Munich Longitudinal Studies of Giftedness began in 1985 with a national sample of 26,000 children and adolescents in six cohorts (Perleth & Heller, 1994). Participants were identified based on a multi-dimensional definition of giftedness and followed through quantitative and qualitative measures of cognitive, personality, and achievement variables. The most comprehensive ongoing longitudinal study of giftedness in the world, the researchers publish regular follow-ups on various developmental issues and educational concerns.

#### *IQ-Related Studies*

One of the larger categories of new and on-going longitudinal studies found in the literature since 1993 comprises IQ-related studies. Several publications address the Terman data, and others report on the Fullerton Study, a 20-year follow-up of a cohort of Californian babies. These two studies have shaped the thinking about life-span studies in profound ways. In addition, a series of studies conducted in three different countries looks at the stability of IQ scores and the relationship of IQ to creativity and personal characteristics.

The Terman study, begun in the 1920s when the subjects were between nine and eleven years old, is the longest published investigation of human development. A series of books, *Genetic Studies of Genius*, (Terman, 1925; Terman & Oden, 1947, 1959, etc.) covered the childhood, early adulthood, and middle age of these high IQ men and women. Terman's protégés, and their respective protégés continue to collect information related to geriatric health and psychology. In addition, the publicly available data have been re-analyzed by countless scholars and graduate students. Holahan, Sears & Cronbach (1995) report on the development of the 'Termites' in their sixth and seventh decades. The focus is on the variables associated with successful aging through explorations of retirement and sources of

life satisfaction. Cronbach (1996) conducted a re-analysis of the Terman data comparing males who completed high school at a normal rate with those who graduated at age 15 or 16 on variables associated with life satisfaction and accomplishment through late middle age. Elder (1987) studied the impact of the type and timing of wartime military service on the later lives of Terman study men. Subotnik, Kassan, Summers & Wasser (1993) compared the Terman group at mid-life with those of a cohort of high IQ adults who attended the highly selective Hunter College Elementary School in the 1940s and 1950s. The level drive and ambition in the Hunter group mirrored the small proportion of Terman study subjects who achieved eminence.

Gottfried, Gottfried, Bathurst & Guerin's (1994) contribution is methodologically unique. They began their study in 1979 by collecting data on the physical, cognitive, and social development of 130 one-year-olds who had all been born at the same community hospital within a specified time period. The subjects were tested for IQ at age eight and categorized as gifted or not-gifted, thereby providing a natural comparison group and avoiding validity issues associated with selection bias. In 1996, Gottfried and Gottfried reported that subjects categorized as gifted demonstrated significantly higher tested intrinsic motivation than unselected peers.

Other important longitudinal studies furthering the validity of IQ were conducted in Israel, Eastern Europe, and United States. Cahan and Gejman (1993) investigated the stability of IQ scores in 161 gifted Israeli children. A new repeated measures study was initiated by Belova (1996) to examine developmental characteristics of gifted East European children over time, with a special focus on the interaction between creativity, intelligence, and personality. The revised Wechsler-Scale for children was employed by Americans Spangler and Sabatino (1995) to test the reliability of test scores used to identify children admitted to special programs for the gifted over the course of six years.

No discussion of IQ can be complete without addressing the work of Flynn (1999), who brought global attention to the trend of rising IQ scores unaccompanied by increased indications of achievement in countries like the United States. The Flynn Effect serves to remind us that high IQ has limited explanatory power in predicting real world achievements.

### *Gender Differences Studies*

Differences in achievement, life satisfaction, career choice, and other key psychological measures based on gender remain of great interest to researchers. *Women's Lives through Time* (Hulbert & Schuster, 1993) includes a 29-year follow-up study of career and life aspirations and accomplishments among 1961 women graduates of the University of California at Los

Angeles (Schuster, Langland & Smith, 1993). A second chapter in Hulbert and Schuster re-analyzed the Terman data for female subjects (Tomlinson-Keasy, 1993). In an ongoing longitudinal study of American students ranked first in their high school classes, Arnold (1993a, 1993b, 1995) found that exceptional high school grades predicted post-secondary academic achievement and degree attainment. However, non-academic factors, such as gender, social class and ethnicity, overshadowed academic talent in determining career accomplishments by the former valedictorians. The most glaring differences in career and life satisfaction outcomes were between women and men. A later collaboration with Subotnik (1996), which included subjects from both the Valedictorian Project and Subotnik's Westinghouse study (Subotnik & Steiner, 1994) showed that women's conceptions of their role as parents continue to shape their career aspirations. Those who were on the 'fast-track' to high level science careers discussed their views of balancing family and work responsibilities, revealing a preference for balance over exclusive focus on work. The authors speculated as to whether their potential for future eminence would be jeopardized in the unforgiving career trajectory of research science.

In a related study, both girls and boys in a special program for mathematically gifted adolescents lost interest in mathematics during their two years in the program (Terwilliger & Titus, 1995). The girls' interests were less strong initially and dissipated much more dramatically than the boys. A Norwegian longitudinal study of school children between ages 10 and 16 found similar gender differences (Undheim, Nordvik, Gustaffson & Undheim, 1995). In that study, high-ability girls and boys were identified as the top 5% of scorers on a variety of cognitive ability tests taken by an unselected sample of 1000 10-year olds. By the end of middle school, at age 16, three to four times as many high-ability boys as girls earned top grades in mathematics. Furthermore, high-ability girls did not show the same superiority over gifted boys in English and Norwegian language study that characterized the larger sample of unselected students.

Kerr (1994) followed up on the women in her elementary school class of gifted students at the 10 and 20 year marks. Decisions made by the women in her group during their early years profoundly limited their later choices. Those who focused on marriage and family later in life were more likely to have met their aspirations. Some of Kerr's research participants found their giftedness a boon, while other women felt defensive about not using their high potential.

Runco (1999) reported on the latest data collected on a 20-year follow-up of two groups of gifted boys, one group with high IQs and a second with high scores on the SAT-M. Various predictive variables associated with creative productivity were explored, including mothers' expectations for their sons' independence as

it relates to flexibility and divergent thinking ability in men's adulthood.

Although an interest in gender differences remained strong for researchers since the last edition of the Handbook appeared, a marked reduction of studies that included ethnic differences is evident. Garrison (1993) addressed the interaction of sex and ethnicity on identification, academic performance, and course selection with a diverse population of American students moving from the middle to the upper secondary school years. Surprisingly little longitudinal work has been conducted on gifted children with disabilities. Only two studies appeared in the English language literature since 1993. Vernon & LaFalce-Landers (1993) studied 57 American children with hearing impairments who were monitored over time on variables associated with their education, career, and mental health status. Over one-third had undergone therapy to address psychological problems including mental illness and less than half had acquired a baccalaureate level education by their early 20s, indicating a clear need for more research and intervention. A British study described the 16-year effects of treatments given to maladjusted able and highly able boys designed to help them succeed in school and in relationships (Lowenstein, 1996).

#### *Education-related studies*

Longitudinal research on the effects of educational experiences and schooling constitute another thread among prospective studies of giftedness and talent. Among this category are studies of the effects of educational interventions and the characteristics of gifted teachers.

Follow-up studies of participants in specific gifted educational programs are surprisingly rare. The most ambitious longitudinal study in progress in this arena comes out of the US National Research Center on the Gifted and Talented. The Learning Outcomes Study (Delcourt, Loyd, Cornell & Goldberg, 1994) began with a national sample of approximately 1000 elementary school students as they entered school programs for the gifted in grades 2 and 3; to date, only cross-sectional findings have been published. The purpose of the study was to compare the cognitive and affective outcomes of participants in the four common types of classroom arrangements for gifted education: within-class; pull-out; separate class; and special school.

Robinson and associates found positive effects of a constructivist classroom approach in a 2 year treatment/control study of early primary school students who displayed advanced mathematical skills (Robinson, Abbott, Berninger, Busse & Mukhopadhyay, 1997). A Canadian longitudinal study of gifted fifth graders demonstrated at least short-term positive effects in performance and attitudes of students grouped in heterogeneous as opposed to homogeneous ability classrooms (Shields, 1996). German and Amer-

ican follow-up studies, in contrast, have provided support for the practice of acceleration and grade skipping for gifted students (Swiatek, 1993; Burks, 1994; Prado & Schiebel, 1995).

In an unusual longitudinal project related to education, Sears, Marshall & Otis (1994) traced the professional development of five high-ability prospective public school teachers from their identification as high school seniors to their entrance into the teaching profession. Study subjects were indistinguishable from less academically gifted teachers in their professional attitudes and teaching performance. The authors concluded that education reform efforts that focus on recruitment of highly academically able teachers will not result in a better teaching force.

The predictive validity of school-based definitions of talent has been the basis for a varied group of longitudinal studies. Austrian researchers investigated the conditions that affected the stability of high level cognitive competence, school grades, and task commitment from early childhood to early adolescence (Speil & Sirsche, 1994). Israeli children from all segments of society were identified as talented in the arts or sciences by teacher ratings and portfolio assessment by professionals. Sixty children have been followed for seven years (Zorman, 1997). Katchadourian and Boli investigated the enduring effects of an elite college education in their 10 year follow-up study of highly able students who graduated from Stanford University (Katchadourian & Boli, 1994). In addition to assessing graduates' career and personal trajectories, researchers tested the predictive validity of a typology based on intellectualism and careerism which had characterized the participants as college students (Katchadourian & Boli, 1985). Katchadourian and Boli found that the educational elite move into prestigious professional ranks in the decade after graduation; the college typology that explained undergraduates' academic achievement and aspirations did not hold for professional attainment, however. Finally, Bok and Bowen (1998) studied ethnic minority students who had been admitted to Ivy League colleges with high school records and test scores below those of most white classmates. The study showed pronounced positive effects of elite undergraduate education on minority graduates' professional ranking and income.

#### *Studies on Psycho-Social Variables*

Freeman has been conducting a long-term investigation of British youngsters' social and emotional development, particularly in regard to the effects of both parenting and labeling (see this volume; 1991). Not only opportunity, but unforeseen problems can arise from being identified as gifted, especially when the services provided are not suitable to the child's academic needs. Swiatek (1994) compared the effects of acceleration on the self-esteem of gifted youngsters (1994) by following for five years, 340 students, some

of whom were accelerated and some of whom were not.

A methodologically innovative study was conducted by Csikszentmihalyi, Rathunde & Whalen (1993) in which gifted high school students wore beepers and completed journals on their motivational, attention, and emotional state at whatever moment and location they were paged. The goal of the study was to address the factors that would lead some students to choose particular domains of interest and to sustain or diminish their involvement over time.

Hungarian researchers followed the top 10% of 1033 nine-year-old children who were tested on a variety of personality and ability measures (Herskovits & Gefferth, 1995). Retests two years later indicated that approximately a third of the high-ability children showed a significant decrease in their tested ability. Achievement motivation, academic self-concept, and family supportiveness differentiated children who remained high scorers from those whose intellectual potential had dissipated. The authors recommended repeated screening of children who exhibit early signs of giftedness in order to improve identification and support services.

### Summary of Trends in Recent Longitudinal Research

In 1993, we outlined recommendations for future longitudinal studies of gifted populations (Subotnik & Arnold, 1993). More multiple cohort studies were needed, we argued, as well as more cross-cultural and cross-national research, and theory-driven designs. Finally, we saw the need for greater attention to follow-up studies of young children.

Given what we have learned about the development of intrinsic motivation in infancy and early childhood (Gottfried & Gottfried, 1996), and related findings on the central role of intrinsic motivation in talented teenagers (Csikszentmihalyi, Rathunde & Whalen, 1993), it appears that motivation is an especially fruitful avenue for identification and nurturing of highly able students. The juxtaposition of these two studies also points to promising possibilities for analyzing similar variables in populations across multiple studies.

Among longitudinal studies published in English since 1993, we find continued emphasis on IQ tests for identifying giftedness and for establishing longitudinal research populations. Stability of IQ over time is another prevalent theme in the recent literature. Gender continues as a focus for longitudinal study, along with interest in personality factors associated with the fulfillment of early promise in gifted populations.

Having considered the themes characterizing recent longitudinal literature, it is important to note those absent or poorly represented in the set of recently reported studies. As noted above, there was little cross-cultural research conducted even within countries or

communities, a surprising finding given the large populations of immigrants and ethnic minorities in many nations that are home to established researchers. Similarly, cross national studies would inevitably shed light on new approaches to understanding and educating gifted students, yet we found none in the recent literature. A small and emerging category of studies that look longitudinally at gifted individuals with disabilities. Some insights into the factors that enhance or impede the academic and career development of these gifted individuals could be a catalyst for whole new interdisciplinary areas of study.

New program models are not proliferating, nor are studies that compare the efficacy of existing programs over time. We are sorely lacking in evidence-based decision making when it comes to establishing, maintaining, or closing gifted programs. Nor has the press for validating various identification schemes persisted over time: only IQ and SAT studies continued to appear regularly in the longitudinal literature. Comparing the effects of programming or identification using repeated methods is an important gap in our research literature. New multiple-cohort studies are not being reported in the journals, either, at least in the English language.

### Fulfilling the Potential of Longitudinal Research

The central questions of gifted education and talent development continue to be those uniquely suited to longitudinal research designs: are educators identifying and serving the right people? Do high potential children, adolescents, and adults receive appropriate services? What factors can be positively influenced through intentional educational experiences? Only following people through time enables the establishment of causal connections between person, context, experiences, and achievement outcomes.

Despite the close match between longitudinal research methods and the fundamental issues of giftedness, repeated measures studies have fallen short of their potential contribution to education and policy. Recent longitudinal work seldom draws directly on either the emerging theoretical insights of the gifted field or the theoretical and methodological advances of sociology and developmental psychology. We suggest several directions to capitalize on the advantages of longitudinal methods.

#### *Development in Context*

Historical and cultural contexts play important roles in determining the forms of individual adaptation and development, and an explosion of theoretical and methodological work in the social sciences concerns contextual issues (Elder, 1974; Bronfenbrenner, 1979, 1993; Dannefer, 1984; Elder, Pavalko & Clipp, 1993; Lerner, 1996). Life course research has emerged over the past few decades, with a robust literature based in

psychology and sociology (Giele & Elder, 1994). Different life paths, according to this model, result from the interaction of human agency (such as motivation, ability), one's historical and cultural location in time and place, the linked lives created by social relations, and the confluence of age, period, and the timing of life events (Giele & Elder, 1994). The importance of historical period and the actual sequence of life events are particularly important contributions of this literature. The life course model could speak directly to conceptualizing and specifying long-term effects of gifted identification, education, and talent development conditions.

The reciprocal interaction of persons and environments has been theorized and researched extensively outside the gifted field, but could be strengthened in the recent longitudinal work reviewed here and in future repeated measures designs. Some researchers of the gifted have incorporated Vygotskian theoretical understandings into cross-sectional or very short term follow-up studies of classroom instruction (see Chapter by Kanevsky). Theory viewing talent development within systems of individual, domain, and field also provides a promising framework for considering individuals within social and historical contexts (Gruber & Davis, 1988; Feldman, Csikszentmihalyi & Gardner, 1994).

In addition to capitalizing on advances in related social science disciplines, longitudinal research could benefit from a closer alignment with emerging insights about giftedness and talent within our own field, including conceptualizations about talent development versus schooling (Bloom & Sosniak, 1981; Subotnik & Coleman, 1996; Subotnik & Olszewski-Kubilius, 1997), attention to underachievers and at-risk gifted populations, and new schooling arrangements such as governor's schools and early entrance programs. None of these issues anchor recent longitudinal work, although the Learning Outcomes Study of comparative gifted program effects (Delcourt et al., 1994) might offer a particularly promising model of theoretical and practical significance for gifted education.

### *Longitudinal Methodology*

More sophisticated theoretical models for longitudinal studies must be accompanied by stronger methodological designs in order for longitudinal research to reach its considerable potential in illuminating giftedness. Multiple cohort, cross-cultural, and cross-national designs are necessary to overcome threats to validity by cohort, period, and cultural effects in single-cohort longitudinal studies. Control groups also strengthen repeated measures studies. Many longitudinal studies use extremely small samples. Although small samples may be appropriate for intensive qualitative inquiries or exploratory studies, subject attrition and statistical power considerations argue for larger study groups wherever possible.

The Study of Mathematically Precocious Youth and the Munich Longitudinal Study of Giftedness are welcome examples of large-sample, multiple cohort longitudinal investigations. However, such studies involve enormous human and financial resources. Short of starting a series of similarly large research projects, several avenues remain open for improving the quality of longitudinal studies. Secondary analysis of existing longitudinal data sets is an especially promising direction for research; existing data may be mined in light of new questions, sub-populations, and theory-testing. The many re-analyses of the Terman data are good examples of this type of secondary analysis. Another extremely valuable form of secondary analysis that satisfies the need for large samples and multiple cohorts is re-analysis of gifted subgroups from nationally representative longitudinal study samples. In the United States, researchers have employed the NELS-88 follow-up of a nationally representative student cohort in order to ask specific questions about gifted populations (see for example Owings, 1995; Russell & Meikamp, 1995; Sayler, 1996). Much of the NELS-88 work presented at academic meetings will appear in published form in the next few years.

Quantitative data from national longitudinal studies are readily available electronically; provision of data sets internationally would stimulate valuable comparative research. Qualitative longitudinal data are equally valuable for secondary analysis. The Murray Center for the Study of Lives, at Radcliffe College, provides an archive of raw qualitative and quantitative longitudinal study data from secondary analysis, replication, and follow-up. The promise of longitudinal inquiry requires the full utilization of existing data sets along with well-designed and theoretically-grounded new longitudinal studies.

Secondly, investigators can analyze findings across two or more existing longitudinal studies; cross-study analysis can provide information on variables of interest for different birth cohorts, age groups, and cultural or national populations. Meta-analysis of single-cohort longitudinal studies can reveal recurring patterns of findings about talent development. Researchers can replicate existing studies or collect a new wave of data on a previously followed study population. In order for a more robust cross-study and cross-national investigations, the field needs better dissemination of longitudinal studies previously unpublished in English or unavailable internationally.

Third, retrospective data may be helpful in answering some research questions, especially when combined with cross-sectional or prospective information. The life course approach provides a theoretical framework for multiple methods in tracing individual trajectories. Questions about the timing of major life events, such as the effects on career attainment on the timing of women's marriage, childbirth, and labor force participation, lend themselves to retrospective

designs. Researchers of the gifted need longitudinal and retrospective life course research designs that similarly investigate the differential effects of the timing of life events.

#### *Proximal Distance*

As noted above, the study of the fulfillment of talent has been conducted using two approaches. One involves the retrospective study of individuals who have met with notable success in achieving some desired outcome, whether the Nobel prize or admission to Stanford University. Participants of these studies are asked to reflect on the variables that led to reaching this goal. Another line of research identifies promising candidates in a cohort and monitors their progress toward attainment of one of these goals.

Retrospective studies suffer from selective memory, when subjects' reflections are colored by their current perspectives and psychological state. Long-term repeated measure studies tend to be inefficient; that is, very few members, if any, of the original cohort will achieve the desired outcome. We would argue that the best way to understand the trajectory of talent is to plan a series of longitudinal studies that work backwards from some valued end goal. An example follows.

Zuckerman (1977), provided a thorough account of the work and training of American Nobel laureates in science. She reported that 55% had attended the same five doctoral universities, and 52% had worked in the laboratory of a former laureate. Based on this work, it appears that (a) attendance at an elite university, and (b) mentorship by a laureate are good precursors for achieving eminence in science. The laboratory of a Nobel laureate is, therefore, an excellent place to start a longitudinal study of eminence in science; the lessons of the eminence literature could be brought to bear on this investigation. Researchers could administer IQ tests, (Roe, 1954), create personality profiles (MacKinnon, 1978), assess effects of marital and parental status (Kerr, 1994; Subotnik & Arnold, 1995), or map professional networks and tacit knowledge (Zuckerman, 1977; Wagner & Sternberg, 1986). We would then be able to get some insights into what distinguishes those who become and remain creatively productive over time from those who do not.

The next stage of the research would be to look at the applications of those who apply to work in the laureate labs. What distinguished the applications of those who were especially creative? What happened to those who were rejected from the lab who had similar characteristics? In this way, the researchers would work backwards in time, establishing the strongest possible levels of predictive validity along the way.

#### *Conclusion*

The essence of longitudinal research is predictive validity; this method of investigation is designed to answer questions like, how well does the Juilliard

audition process select for solo violinists? How effective is the challenge provided by the Talent Search process in maintaining academically talented adolescents' interest in school? How does the imminence of the biological clock affect the decision making of female scientists? The answers to these sample questions are innately interesting, but more importantly, they provide road maps to interventions that may make talent development more efficient, and open the doors to greater inclusion in the process.

Scholars who investigate the development of giftedness and talent are in an excellent position to extend the sophistication and applied usefulness of repeated measures methodology. We repeat our 1993 call for a more complex approach to the study of predictive validity. The education public wants to know whether special programs or groupings meet the goals ascribed to by the program designers. The education community also wants to know if we are selecting the 'right' students. What is the effect of identifying and serving only the most talented? What happens when students who exhibit some potential in spite of incredibly difficult circumstances are served in gifted programs? At what point, if ever, is it too late for them to become 'competitive' with their advantaged peers? Finally, what components of the talent development process (and what domains) are most suitable to replication in schools? If we want to broaden the possibilities for children to discover and build on their potential talents, more of the talent development process will have to be accessible in schools. Longitudinal studies are the best way to address these questions, and we look forward to harvesting the results of those investigations.

# A 'Talent' for Knowledge and Judgment about Life: The Lifespan Development of Wisdom

M. Pasupathi<sup>1</sup> and U. M. Staudinger<sup>2</sup>

## Introduction

Most people would agree that wisdom is of great value to individuals and to societies. In the historical wisdom literature, it is often viewed as one of the four great virtues of paramount importance for human societies, and historically, even as a divine gift (Assmann, 1994; Kekes, 1995; Almond, 1997; Baltes, in press). Giftedness has similarly been characterized, and even lauded as the only human characteristic that could help us survive and evolve (Toynbee, 1967).

### *Wisdom as Divine Gift*

Assmann (1994) reviews the historical transformation of wisdom into a divine quality during the Hellenistic period; thereafter, wisdom was a gift given by the gods. Within Christian traditions, wisdom became something achieved via revelation, prayer, faith, and vision. This divine gift was viewed as distinct from knowledge and as an antidote to human foolishness during the Middle Ages. During the Renaissance, the view of wisdom as a divine gift became questionable once more, as well as secularized. From current conceptions of giftedness and talent, the gift character of wisdom reappears, though in a different light.

### *Wisdom as Giftedness or Talent*

Current ideas about giftedness often touch base with what we would think of as wisdom, when they emphasize talent for insightful psychological understandings about the self or other, or the integration of history, religion, and philosophy to bring new insights about societies and individuals (DeHaan & Havighurst, 1957; Phenix, 1964; see also Gardner, 1993). Other

conceptions of giftedness and talent have emphasized abilities like productive thinking, communicating, forecasting, decision-making, planning, implementing, human relations, and detecting opportunities (Taylor, 1986). Probably someone having a talent for all of these activities would be likely to be called wise as well. As we will discuss later in this chapter, parallels between conceptions of wisdom and giftedness are many, and multiple relationships between wisdom and giftedness can be fruitfully considered and have the potential to lead to interesting empirical work. Depending on the theoretical perspective taken on giftedness, some researchers would consider wisdom a kind of talent. Based on our conception of wisdom we would argue that wisdom may be better viewed as a *meta-talent*, comprised of knowledge and skills across many domains and the capacity to select and appropriately combine aspects of these domain-specific talents. We will return to this issue later in the chapter.

In this chapter, we concern ourselves with two general questions. First, what do we know from psychological research about the development of wisdom? Three general developmental predictions can be distinguished in the literature, and we present evidence bearing on these views. Second, how might wisdom and giftedness be related? In this part, we consider four ideas. First, can wisdom be viewed as a type of giftedness? Second, can giftedness itself help or hinder the development of wisdom? Third, is the life event of being identified as gifted one that facilitates the development of wisdom? We conclude with a discussion of the potential and peril in considering wisdom and giftedness together and of some of the common issues facing researchers interested in either of these concepts.

## Developing Wisdom: Conceptions and Findings

Many people believe that age is the bringer of wisdom (Clayton & Birren, 1980; Sternberg, 1986; Sowarka,

---

\* Center for Lifespan Psychology, Max Planck Institute for Human Development, Berlin, Germany. Now at University of Utah, Department of Psychology, Salt Lake City, USA.

\*\* Center for Lifespan Psychology, Max Planck Institute for Human Development, Berlin, Germany. Now at Dresden University of Technology, Department of Psychology, Lifespan Development Area, 01062 Dresden, Germany.

1989; Orwoll & Perlmutter, 1990). But what is meant by wisdom? Wisdom has been variously conceived of as a quality of personhood, a feature of actions, a body of knowledge ('the wisdom of the bible'), or an expertise in difficult and fundamental aspects of life (Baltes, Smith & Staudinger, 1992; Oser, 1998). Wisdom is often seen as knowledge about the human condition at its boundaries, knowledge about the most difficult questions of the meaning and conduct of life, and knowledge about life's uncertainties. Commonalities in psychological definitions have emphasized the search for a moderate course between extremes, a dynamic between knowledge and doubt, sufficient detachment from the problem at hand, and a well-balanced coordination of emotion, motivation, and thought (see Staudinger & Baltes, 1994 for a review).

Psychological approaches to studying wisdom can be viewed as emphasizing either implicit views of wisdom, that is, the opinions and beliefs people hold about wisdom and wise people, or focusing on explicit theories of wisdom (Sternberg, 1990; Staudinger & Baltes, 1994; see Pasupathi & Baltes, 1999). Explicit theories typically define wisdom and then proceed to evaluate the degree to which expertise, knowledge, an action, or a person demonstrates wisdom as defined. Such theories sometimes point to the processes involved in producing wisdom, whether ontogenetically, or in terms of the particular response or task context. In the present chapter, we focus our review of empirical evidence primarily on explicit theories of wisdom, although we do review some of the findings on implicit theories in constructing different predictions about the development of wisdom.

Three different developmental courses for wisdom have been proposed in the literature. One suggests that age is associated with decreases in wisdom; a second implies that age should be associated with increases in wisdom, and a third proposes that complex qualities like wisdom are unlikely to show clear and consistent relationships with age, particularly in adulthood. Below, we review the theoretical frameworks leading to each of these three predictions in turn.

### *Aging and Loss of Wisdom*

Walker Percy has argued that expertise can obscure our ability to really see what confronts us, hiding the thing observed behind a web of concepts and prior explanations. "The technician is never vague and never humble before the thing; he holds the thing disposed of by the principle, the formula, the textbook outline; and he thinks a great deal of equipment and jargon" (Percy, 1975, p. 61). Meacham (1990) makes a similar argument about wisdom. He proposes that the essence of wisdom is a view of knowledge as fallible, and a subsequent ability to strike a balance between doubt and certainty; this essence, he claims, is not developmental in that it is available to people of all ages. He goes on to suggest that a second dimension of wisdom

concerns the profoundness of the domain in which wisdom is being expressed, and that this dimension may vary systematically with age. Finally, he argues that children may represent the peak of wisdom, with development over the lifespan characterized by either maintenance or loss of wisdom. He argues, in fact, that it is easier to lose rather than gain wisdom as we mature, either by gaining knowledge and therefore inappropriate levels of certainty, or by becoming overwhelmed with contradictory information and therefore doubt. Meacham appears to exclude the idea that development not only brings more certainty or more contradiction, but might also lead to a balance between certainty and doubt, nor does he provide empirical findings directly testing his interesting predictions. This is a view presented by other conceptions of wisdom, and the evidence reviewed below thus has implications for Meacham's view as well. Further, increasing personality rigidity and decreasing openness to experience with aging, along with losses in cognitive ability (Costa & McCrae, 1994; Schaie, 1995; Baltes, Lindenberger & Staudinger, 1998) suggest that some of the ingredients necessary for wisdom may in fact be lost with increasing age (Staudinger, 1999).

### *Gaining Wisdom with Age: Implicit Theories, Personality and Neo-Piagetian/Post-Formalist Approaches*

Among the most commonly shared, or even stereotypical, assumptions about wisdom is that older adults are more likely to possess it (Clayton & Birren, 1980; Sternberg, 1985; Sowarka, 1989; Orwoll & Perlmutter, 1990). It must be noted, though, that age is not typically the most central characteristic in people's images of a wise person. Further, the older the person being asked, the less likely it is that age and wisdom are viewed as connected (Clayton & Birren, 1980).

Stage-like developmental frameworks underly both personality approaches to wisdom (e.g. Erikson, Erikson & Kivnick, 1986) and post-formalist or neo-Piagetian approaches (e.g. Alexander & Langer, 1990; Kitchener & Brenner, 1990; Kramer, 1990). Typically, these approaches argue for a sequential, stage-like emergence of the personality characteristics or cognitive ability considered central to wisdom; such approaches do not imply that all people eventually attain wisdom. Rather, there are personality stages (or resolved psychological crises) and/or cognitive abilities that serve as important and necessary prerequisites for wisdom, and that the eventual attainment of wisdom occurs relatively later in adulthood. This in turn implies that wisdom should be positively correlated with age.

According to the Eriksonian theory of personality development, personality develops via a sequence of age-related crises (Erikson, Erikson & Kivnick, 1986; Whitbourne, Zuschlag, Elliot & Waterman, 1992). The crisis of late life involves coming to terms with one's life-as-lived, including both the successes of that life

and the failures and unresolved problems. Mastery of this crisis leads to ego-integrity, or wisdom, according to many theorists (Erikson et al., 1986). Because earlier crises and their resolutions are viewed as contributing to later ones, the crisis of middle-age, which concerns whether and how to be generative (e.g. either by bearing and raising children or via professional contributions), may also be an important contributor to wisdom. When ego-integrity and generativity are successfully resolved, the result is someone who contributes to the world and who has a sense of integrity about themselves and their life. Both of these qualities figure centrally in implicit views of wisdom (e.g. Orwoll & Perlmutter, 1990). Other personality conceptions, such as the notion of developmental changes in psychological maturity (e.g. Vaillant, 1995), also imply increases in wisdom with increasing age; the empirical evidence employing personality approaches to wisdom is limited. Those nominated as wise do score higher on measures of ego-integrity (Orwoll & Perlmutter, 1990), confirming the validity of this approach to studying wisdom. Older adults do show higher ego-integrity than younger adults, although not all older adults attain ego-integrity (Ryff & Heincke, 1983; Whitbourne et al., 1992). Vaillant (1995) has provided substantial evidence for increasing psychological maturity in his longitudinal studies, but these studies focus on a relatively elite group of individuals.

Post-formalist or neo-Piagetian approaches to wisdom concentrate on features of thinking or reasoning, such as the structure with which people reason about problems, the stance people take on knowledge, or the degree to which people integrate cognitive and affective information in their thinking (e.g. Kramer, 1990; Labouvie-Vief, 1980). A common thread in many of these approaches is the notion of uncertainty or fallibility of knowledge, consistent with Meacham's propositions; relativism, and the ability to make sense of conflicting elements in a dialectic or synthesized whole, are also emphasized. Here again, though specific theories vary, the usual proposition is a series of increasingly advanced, mature, or wise stages in thinking through which people progress in a linear fashion. Although not all individuals are expected to show increases, and not all individuals are expected to attain the top levels of performance, the general expectation is one of linear increases with age. However, at which age people are able to attain the 'peak' level of functioning varies with the particular conception of post-formal development examined.

For example, reflective judgment, which involves a person's capacity to understand the fallibility of knowledge and still make conclusions despite this awareness, seems positively correlated with age. Samples examined with this measure have been relatively young, however (Kitchener & Brenner, 1990; Kitchener, Lynch, Fischer & Wood, 1993). Other

approaches, such as that taken by Labouvie-Vief and her colleagues (e.g. Labouvie-Vief, 1980; Labouvie-Vief, DeVoe & Bulka, 1989; see also Kramer, 1990 for similar theoretical views), suggest the importance of integrating cognition and affect in reasoning for developing wisdom. Their work shows improvements in integrative thinking into middle-age, but small to moderate declines in later life (see, e.g. Labouvie-Vief et al., 1989). Thus, the development of cognitive abilities viewed as indicators of wisdom suggests curvilinear development with age, where evidence on the full adult lifespan is available.

#### *Age is not Sufficient for Becoming Wise: The Berlin Wisdom Paradigm*

Our own approach attempts to integrate some of the elements of the theories reviewed so far with additional influences from expertise approaches to development (e.g. Ericsson & Smith, 1991) and lifespan psychology (Baltes, 1987). We have defined wisdom as "an expert knowledge system in the fundamental pragmatics of life permitting exceptional insight, judgment, and advice involving complex and uncertain matters of the human condition" (Baltes & Smith, 1990, p. 95). Wisdom-related knowledge and judgment apply to difficult problems in managing, planning, and making sense of life. Such knowledge is characterized more specifically by a family of five criteria (see Table 1).

Two of the five criteria (rich factual and rich procedural knowledge) are drawn from general conceptions of expertise (e.g. Chi, Glaser & Farr, 1991; Ericsson & Smith, 1991). Factual and procedural knowledge about the conduct, interpretation, and meaning of life are *basic* criteria in that they are necessary but not sufficient for defining wisdom-related knowledge and judgment. The remaining three criteria (lifespan contextualism, value relativism, recognition and management of uncertainty) are *meta*-criteria, and are viewed as specific to the fundamental pragmatics of life. They are grounded in the cultural and historical literature on wisdom (Assmann, 1994; Baltes, in press), neo-Piagetian research as reviewed above, and propositions of lifespan developmental psychology (e.g. Baltes, Lindenberger & Staudinger, 1998). Assessment of an individual's wisdom-related knowledge and judgment follows from the definition and employs these five criteria. Study participants are presented with difficult and ill-defined life dilemmas faced by hypothetical people, and are asked to think aloud about what the person facing the situation might do or consider. Following a standardized procedure (Staudinger, Smith & Baltes, 1994), a carefully selected, extensively trained, and well-calibrated rater panel evaluates how well responses reflect the five criteria outlined above. Note that this expertise-related approach resonates with the literature on giftedness; some researchers argue for reconceptualizing giftedness as expertise in a particular domain

Table 1. A Family of Five Criteria Used to Evaluate Wisdom-Related Performances.

Basic criteria	High performances demonstrate . . .
Rich Factual Knowledge About Life	consideration of general (human condition) and specific (e.g. life events, institutions) features of life matters as well as scope and depth in coverage of issues.
Rich Procedural Knowledge About Life	consideration of decision strategies, goal selection, choosing means to achieve goals, people to consult with, as well as strategies of advice-giving.
Meta criteria	High performances demonstrate . . .
Lifespan Contextualism	consideration of past, current, and possible future life contexts and the circumstances in which a life is embedded.
Value Relativism	consideration of variations in values and life priorities and the importance of viewing each person within an individual framework, but also the importance of a small set of universal values oriented towards the good of others and oneself.
Awareness & Management of Uncertainty	consideration of the inherent uncertainty of life (in terms of interpreting the past and predicting the future) and effective strategies for dealing with uncertainty.

(Adapted from Baltes et al., 1992)

(Gruber & Mandl, 1992). However, expertise approaches also imply the routinization, and resulting lack of flexibility, of knowledge use. The meta-criteria concerning the awareness and management of uncertainty is meant to require that wisdom involve transcending the limitations of 'typical' expertise, and that those who are wise retain flexibility 'despite' expertise.

Thus far, we have addressed how wisdom is conceptualized and assessed in this model, but not the expectations about the ontogeny of wisdom derived from this model. Our developmental framework is shown in Fig. 1. As depicted, general person characteristics like intellectual capacity, personality, social skills, or creativity are related to whether individuals develop wisdom or not. The model also proposes

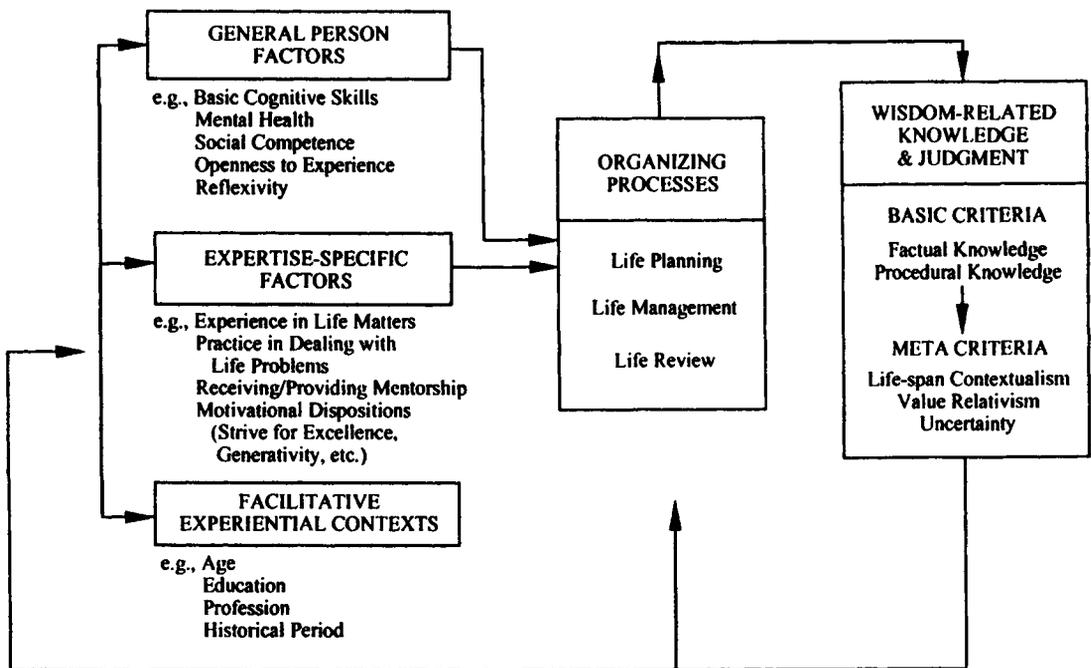

Figure 1. Ontogenetic model of the development of wisdom-related knowledge and judgment.

expertise-specific factors in the development of wisdom, which include access to relevant experiences, extensive practice, mentorship for making use of such experiences, and the motivation to excel at knowledge and judgment about life. Individual differences in motivation and access to relevant experience are expected to be critical in terms of who becomes wise and who does not. A final category of factors, termed facilitative experiential contexts, highlights the way in which age or profession provide differential access to experiences relevant for the development of wisdom. Such contextual variables also, as shown, may be related to general person qualities; as when specific personality characteristics are more prevalent among some occupational groups than in others or particular aspects of intellectual ability improve or decline over adulthood (see, e.g. Staudinger, Maciel, Smith & Baltes, 1998).

All of these factors are 'activated' by a set of organizing processes—those of life planning, management, and review—which provide an instance for the activation, transformation, and expression of wisdom-related knowledge and judgment. Such processes are considered critical for the acquisition of wisdom-related knowledge and judgment within our model, but are only beginning to be considered (see Smith, 1996; Staudinger, 2000; Staudinger, 1999). These processes form the core of our own procedure for accessing an individual's wisdom-related knowledge.

As is probably clear, this framework does not imply any obvious linear relationship between age and wisdom. Rather, it suggests that a complex interplay

between experience and individual can allow for the emergence of wisdom, or at least for high levels of wisdom-related knowledge and judgment, at any adult age. Age may allow for time within which experience can be acquired, but may also produce changes that are less supportive of wisdom, as we discuss in more detail below (see also Staudinger, 1999). Not only is the role of age potentially both facilitative or debilitating, leading to no clear age-wisdom expectations, but there are many roads to wisdom in Fig. 1, and not all intersect with age.

What about the evidence? Our own findings have been thoroughly summarized elsewhere (Staudinger, 1999), and the story about age-relationships with general wisdom-related performance is relatively simple. Across several studies with heterogeneous samples of adults (ages 25–80 years), we have found no systematic relationships between our measure of wisdom-related performance and age. In a more recent study of adolescents and young adults, a much stronger age relationship emerged ( $r=0.46$ ; Pasupathi, Staudinger & Baltes, 2000). Figure 2 shows the relationship between age in adulthood and wisdom-related performance across several studies. As can also be seen in Fig. 2, a slightly more negative relationship emerges for participants over age 80 (see Baltes et al., 1995; Staudinger, 1999, for discussion).

In sum, as can be seen, age plays a much smaller role in wisdom than might be expected from stereotype or common sense views. Generally, findings support the expertise-contextual model in that there is no clear relationship with age for wisdom-related performance.

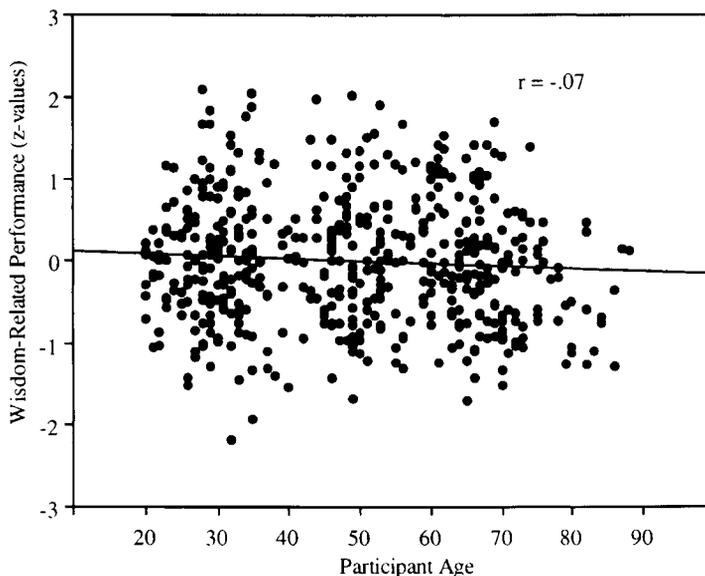

Figure 2. During adulthood (25–75 yrs.), it is not enough to grow older to become wiser.

At some stages of life, there is a normative age relationship—specifically, during adolescence, almost all data suggest growth. Similarly, during very old age, enough people may show declining performance, although more data are needed for this later part of the lifespan. In between, probably some individuals do become wiser, or even wise, over time; while others may remain stable, and others actually show decline. Which people show what developmental pattern may be predicted by features of the ontogenetic model described above, that is, by individual differences in personality, intelligence, and experiences.

Below, we shall see that when the correlates of wisdom-related knowledge and judgment in our own work are examined, potential explanations for age stability emerge. Two of these explanations are (1) the complexity of typical developmental changes in factors which facilitate or support wisdom-related performance and those which are detrimental to that performance, and (2) the relatively unexplored territory of individual differences in developmental trajectories for these same factors. An additional relatively unexamined issue concerns within-person patterns of wisdom-relevant characteristics. Below, we turn to the more complex picture emerging from examining wisdom-relevant characteristics; in doing so, we focus on the antecedents identified in our own ontogenetic model.

#### *Person Characteristics and Their Contribution to the Development of Wisdom*

Individual differences in the antecedents for the development of wisdom are presumed to relate to who becomes wiser and who does not. Such differences could take at least three (potentially inter-related) forms. First, stable mean-level differences in factors which support the acquisition of wisdom may predict which individuals become wise in adulthood. Those individuals who are creative and reflective may simply be advantaged in the attainment of wisdom. Second, differences in individuals' *development* of these supportive factors may influence which individuals attain greater life insight or maintain such insights for a longer time. For example, a person who remains open to experience throughout their adulthood may continue to acquire the kind of knowledge and judgment associated with wisdom; another person who becomes increasingly rigid from early adulthood to old age may eventually lose the ability to respond reflectively and sagely to a difficult life problem. Third, individuals may differ in the profile of characteristics and experiences they have, with some patterns of characteristics facilitating wisdom and others not. A person who has many difficult life experiences may gain insight only in combination with other qualities, such as a structured and reflective way of thinking about those experiences or a motivation to gain insight, or both. Below, we take the ontogenetic model as a framework and review what

is known about the typical developmental trajectory of characteristics associated with wisdom-related knowledge and judgment.

*Intelligence.* Our conception views wisdom as a prototype of the pragmatics of the mind (see Baltes, Lindenberger & Staudinger, 1998; Staudinger, 1999), that is, the aspect of intelligence characterized by content-rich, knowledge-driven processing. This implies that indicators of cognitive pragmatics, such as vocabulary or practical knowledge, will be more strongly related to wisdom-related performance than indicators of cognitive mechanics, such as fluid intelligence. This has in fact been the case in both adolescent and adult lifespan samples (Staudinger, 1999; Staudinger & Pasupathi, 2000). Intelligence has not been a unique predictor of wisdom-related performance in adult samples (see Staudinger, 1999). In relatively elderly populations and in adolescent populations, however, where intellectual functioning may drop below a critical threshold required for performance, intelligence appears to play a stronger predictive role than across the remainder of adulthood (Baltes, Staudinger, Maercker & Smith, 1995; Staudinger & Pasupathi, 2000; Staudinger, 1999). Some minimum level of intellectual ability is required for accessing and integrating knowledge in formulating a response to wisdom-related dilemmas, whether in our laboratory conditions, or in the actual life contexts in which people reason about difficult life matters.

In addition to normative change in intelligence, such as the increases in performance occurring over adolescence, and the decreases identified in later life, there are inter-individual differences in the developmental trajectory of intellectual functioning (e.g., Schaie, 1994; Arbuckle, Maag, Pushkar & Chaikelson, 1998; Baltes et al., 1998). Such differences may be due to differences in mechanisms thought to account for general age-related changes in cognitive mechanics (e.g. working memory capacity or processing speed). Alternatively, different trajectories of cognitive aging may also be due to other factors that appear to moderate individual differences in intellectual change, such as personality traits like flexibility or exposure to environments that are complex and intellectually stimulating (Schaie, 1994). The implication for the development of wisdom-related knowledge and judgment is that individual variability in the development of intellectual capacities across the lifespan may mean that individuals differ in the age at which they do not have the minimum intellectual capacity needed to support wisdom-related performances, whether during childhood and adolescence, or during late life. This in turn, would mean that the age-trajectory of wisdom-related performance would vary across these individuals.

Finally, particular domains of knowledge within the broader category of pragmatics of the mind may be of

special relevance for developing wisdom-related knowledge. Consider the case of knowledge about human psychological functioning—sometimes referred to as theory-of-mind research (see also Staudinger & Pasupathi, 2000). Theory-of-mind has predominantly been examined in young children (infancy through middle-childhood), and results here show increasing sophistication in the way that children and adolescents understand concepts like beliefs, thoughts, and desires, the way that they differentiate between different types of mental activities, and the way they use concepts like that of belief to explain actions (Fabricius, Schwanenflugel, Kyllonen, Barclay & Denton, 1989; Perner, 1991; Flavell, Green & Flavell, 1995). In one study, improvements were demonstrated across the adult lifespan, with older adults actually outperforming other groups in terms of the complexity of their belief-based reasoning (Happé, Winner & Brownell, 1998). As another special case, consider knowledge about typical adult biographies. Here, too, the evidence points to increasing knowledge about both typical and idiosyncratic biographies over childhood and adulthood (see, e.g. Greene, Wheatley & Aldava, 1992; Strube, Gehringer, Ernst & Knill, 1985; Heckhausen, 1999).

*Personality.* Among the personality characteristics uniquely associated with wisdom-related knowledge and judgment are openness to experience and an orientation towards personal growth (Clayton & Birren, 1980; Staudinger, Lopez & Baltes, 1997). An additional performance advantage accrues to those individuals who are balanced between being introverted and extraverted. Characteristics like these tend to show small declines with increasing age in adulthood, particularly after middle-age (Costa & McCrae, 1994; Ryff & Keyes, 1995). Normative personality changes may in fact hinder the development and expression of insight about life matters over adulthood (Staudinger, 1999). Of course, here again, there may be wide variability in individual patterns of stability and change over adulthood, and relatively little empirical work addresses the possibility of such patterns (but see Schaie, 1995). Some types of people appear to be ‘changers’ while others remain stable, as identified by Block (1971), and combinations of personality, intelligence, and environmental factors may interact to determine developmental trajectories (see, e.g. Schaie, 1995).

*Interface of personality and intelligence.* Qualities like creativity, social intelligence, and cognitive styles are important predictors of wisdom, demonstrating the largest unique relationships with wisdom-related performance in our own past work (Staudinger, Lopez & Baltes, 1997). Cognitive styles, defined as characteristic preferences for using cognitive abilities in particular ways, represent a prototypical interface between intelligence and personality. People perform-

ing well on our measure of wisdom-related knowledge and judgment display a judicial style—that is, they are more concerned with understanding the reasons for and implications of someone’s thoughts and actions than with judging the thought or action as good or bad (Sternberg, 1990, p. 51). Higher performances are also given by those who are progressive in thinking rather than conservative, and those who are more creative (Staudinger et al., 1997, 1998). Little empirical evidence speaks to developmental changes on these characteristics; during adolescence, people may improve in social intelligence and related capacities (e.g. Gurucharri & Selman, 1982; Keller & Wood, 1989). Creativity, when assessed by standardized tests, may follow a curvilinear pattern of development over adolescence, decreasing from early into middle adolescence, then increasing again (Ross, 1976; Smith & Carlsson, 1985). When actual products are employed in assessing creativity, this appears to peak in early or middle adulthood, depending on the field examined, and then to decline (Simonton, 1990). Further, over adulthood and aging rigidity may increase (Stevens & Truss, 1985; Costa & McCrae, 1994). Even less evidence is available on individual differences in developmental trajectories of creativity or cognitive styles; to the extent that these are viewed as trait-like, non-changing attributes of the individual, change is expected to be minimal. However, Sternberg and Grigorenko (1997) argue that in fact, cognitive styles probably do change over time and across situations, largely dependent on what is rewarded in a particular context at a particular time. Similar arguments have been made concerning creativity and giftedness, also at times viewed like traits (Jackson & Butterfield, 1986).

*Expertise-specific antecedents: life experiences and motivation.* Thus far, we have concentrated on general characteristics of people, normative developmental trajectories in these characteristics, and where possible, individual differences in the way that these characteristics change. We now focus on the role of life experiences in acquiring wisdom-related knowledge and judgment, and briefly address motivational issues, as little empirical work has directly addressed these aspects of wisdom-related knowledge and judgment.

The role of specific life experiences in contributing to wisdom has a large role in implicit views and philosophical approaches (e.g. Jaspers, 1932; Assmann, 1994). Further, different contexts can offer varying opportunities for wisdom-relevant experiences. For example, some types of professional training offer extensive practice and experience in difficult matters of life management, planning, and interpretation. In our own work, clinical psychologists, who receive extensive training and practice in dealing with difficult life matters, outperform other highly educated professionals with less exposure to knowledge of life pragmatics (Staudinger, Smith & Baltes, 1992; Smith, Staudinger

& Baltes, 1994). In one recently completed study we investigated participants' subjective conceptions about the development of wisdom and their wisdom-related performance. First results suggest that mention of events with deeply existential qualities (such as death, guilt) were especially related to higher levels of wisdom-related performance (Staudinger & Reimer, 1999). This finding fits well with Jaspers' notions of existential confrontations and their contribution to deepening insight into human nature (see also Maercker, Böhmig-Krumhaar & Staudinger, 1998).

Both the experience of events and reflecting upon or integrating such experiences appear necessary for extracting wisdom-related knowledge and judgment (Staudinger & Dittmann-Kohli, 1994; Staudinger, 2000). These processes of extracting meaning, in the case of traumatic events, may have implications for later well-being as well (Davis, Nolen-Hoeksema & Larson, 1998). In fact, extracting benefits from a loss, rather than simply making sense of the loss in terms of what the person already knows, seems most important for adaptation over the longer-term (Davis et al., 1998). Identifying and understanding the mechanisms by which people construct meaning and knowledge from their life experiences are an important direction for future work; some existing findings suggest that these mechanisms may vary as a function of age and other person characteristics. For example, older adults report more frequently using the past in preparation for death, and also in teaching or informing others (Webster, 1997). Both of these uses of the past might produce more wisdom-related insight than other functions of remembering, such as using the past to reduce boredom; however, this speculation has not yet been addressed empirically.

How people reflect on their experiences may also be a function of personality, cognitive style, intellectual ability, and motivation, as well as a function of the social contexts in which they perform such reflections. For example, those high in openness to experience tend to reminisce differently than those low on this personality dimension, considering more philosophically weighty issues in their thinking (Webster, 1994). People highly open to new experience also engaged in reminiscence more frequently (Webster, 1994). Such differences suggest that personality influences the way people think about and make sense of their past experiences; such 'processing' differences may in turn have consequences for the amount and quality of knowledge and insight individuals extract. Some preliminary results support this with our own measure of wisdom-related knowledge and judgment. In one study, moral reasoning interacted with age in predicting wisdom-related performance (Pasupathi & Staudinger, in press); this interaction, though based on cross-sectional data, suggested that individuals with high-level moral reasoning ability did gain in wisdom with age. We interpreted this finding, admittedly

speculatively, in terms of experience (assessed indirectly by age) and ways of extracting meaning (principled moral reasoning abilities). Moral reasoning at complex and sophisticated levels may endow people with a rich way of extracting meaning from their experiences. As experiences accumulate with increasing age, the benefits of higher moral reasoning ability for wisdom-related knowledge and judgment emerge. This account is quite preliminary, but suggests one interesting path to wisdom.

*Motivations.* Motivational factors have been identified or mentioned as having great importance in research on talent and giftedness (Renzulli, 1986; Sternberg & Davidson, 1986; Csikszentmihalyi, Rathunde & Whalen, 1993; Gagné, 1993), research on expertise (Bloom, 1985; Ericsson & Smith, 1991; Winner, 1996), and in our own work on wisdom-related knowledge and judgment (Staudinger, 1999). Unfortunately, specific conceptions of a motivation for excellent life insight are not, to our knowledge, available. Perhaps the sorts of biographical factors proposed to lead to generative lives, such as an early sense of purpose and a feeling that one has a duty to society, may also be connected to the motivation to become wiser (see McAdams, Diamond, de St. Aubin & Mansfield, 1997).

Obviously, existing findings on the expertise-specific antecedents of wisdom specified in our own model are sparse—very little work has been done examining mentoring, and an analysis of the role of specific life experiences, and ways of coping with those experiences, is in its infancy. This remains a very promising arena for future research.

*Contextual factors as facilitators of wisdom.* Development, whether of athletic skill or life insight, does not take place in a vacuum of intrapsychic processes. As giftedness researchers note, cultures define what abilities constitute important talents, and talents included in a culture's definition will be supported and encouraged via resources and attention (see, e.g. Sternberg & Davidson, 1986; Csikszentmihalyi et al., 1993; Tannenbaum, 1993). Although cultures tend to show relatively good cross-cultural consensus about the components of wisdom (see Assmann, 1994; Baltes, in preparation), contextual factors may provide more or less support for an individual's development of wisdom. Here, we address the role of contextual factors in the acquisition and expression of wisdom-related knowledge and judgment, with a particular focus on age and cohort.

Although age is not related to wisdom-related performance per se, age may play a role in many ways; it does provide individuals with time within which they can accumulate experience. Further, due to the biological constraints and the societal institutionalization of the life course (Havighurst, 1972), age is sometimes

necessary for certain experiences. These two propositions do imply that a person's age may sometimes matter in responding to wisdom-related dilemmas, particularly when the content of those dilemmas concerns a particular age period.

Findings from two studies suggest that participants sometimes do show performance advantages for problems relevant to their own age group (Staudinger et al., 1992; Smith et al., 1994). This effect, which we call the 'age-match' effect, is more straightforward for life-review tasks than for life-planning tasks. For the former task type, older adults do better than younger adults on older adult problems, younger adults outperform older adults on younger adult problems. For the latter task type, younger adults tend to outperform older adults on younger adult problems; whether older adults show a similar advantage depends on the normativeness of the life problem and the older adults' degree of expertise (see Staudinger, 1999, for more details).

Cohort can also limit people's access to particular kinds of experiences; for example, a sample of individuals nominated by the community as wise had biographies characterized by resistance and/or persecution by the Hitler regime (cf. Baltes et al., 1995). Such experiences are necessarily limited by the historical time of a person's birth. Similar statements can be made of many other variables, including nationality, ethnicity, and gender. Such categories permit or deny some experiences to the individuals who fit into them. The ramifications of major historically-determined experiences, such as combat experience, can extend to the timing of the entire lifecourse (Elder, 1998). Presumably, differences in lifecourse timing can have implications for the development of life insight, both supportive and detrimental; these differences have not been thoroughly examined with respect to wisdom-related knowledge and judgment. These findings do underscore the complexity of developmental approaches to wisdom, reminding us that our knowledge and judgment may be inextricably bound up with our own position in life.

Thus far, we have concerned ourselves primarily with developmental and individual differences in personality, intellectual capacity, interface qualities, and life experiences that have developmental implications for wisdom. We have argued that individual differences in stable personal characteristics, or in access to particular experiences may predict who becomes wise, and who does not. We have also argued that individual differences in the developmental trajectory of these qualities, though relatively under-investigated, also have importance for the development of wisdom. Of course, we want to highlight the fact that complex interactions among these factors may provide many roads to wisdom. One such possibility was mentioned above when we discussed the potential for age, personality and other person characteristics to

influence the way individuals extract knowledge and insight from events they encounter. Another such possibility is raised by the findings mentioned above on moral reasoning, age, and wisdom-related performance. Still a third possibility concerns cross-sectional and developmental profiles of characteristics within individuals, which we know very little about. Such a wholistic picture seems important for understanding a variety of person qualities as well as for understanding the acquisition, maintenance, and expression of wisdom.

### Wisdom and Giftedness

Having now spent some time on the complicated evidence about the development of wisdom, we wish to consider how wisdom intersects with the theme of this Handbook. We believe there are at least three ways in which that intersection can be considered. First and perhaps most straightforwardly, wisdom can be viewed as a talent for a particular domain: the domain of fundamental life pragmatics; we prefer, however, to think about it as a meta-talent, and say more about this below. Second, we may consider how giftedness as a characteristic might help or hinder the development of wisdom; we will refer to these as primary effects of giftedness on wisdom. Third, we consider how the experience of being a gifted child may relate to the development of wisdom, or what we will call secondary effects of giftedness on wisdom.

#### *Wisdom as a Meta-Talent: A Gift for Life Insight*

Whether one looks at conceptual, methodological, or intervention aspects of the literatures, wisdom and giftedness or talent appear to overlap. Our conception of wisdom-related knowledge and judgment, as well as the other views mentioned above, is explicitly not a trait-like approach. In this sense, views of giftedness as a stable, enduring, trait-like characteristic would provide a contrast with wisdom research (but see Mönks & Mason, 1993). However, more recent conceptions of giftedness seem more analogous to our own views about wisdom, emphasizing the interaction and integration of various personal characteristics and socio-cultural factors in the development of giftedness or talent, regardless of which domain. For example, Gagné (1993) conceives of giftedness as potential, and talent as specific ability, and attempts to understand the way that giftedness gets translated (developed) into talent. He regards both individual characteristics, such as persistence, and environmental catalysts, such as encounters with mentors or chance exposure to activities, as critical. Similarly (for our purposes), Renzulli (1986) argues for redefining giftedness in terms of initial above-average ability, motivation (task commitment), and creativity. Finally, as noted earlier, proposals to view giftedness as expertise are well in

line with our own views of wisdom (Gruber & Mandl, 1992; Winner, 1996). In this way, considering wisdom as a kind of talent, in the domain of fundamental life pragmatics, seems appropriate. The very nature of the domain, however, implies that conceiving of wisdom as a meta-talent means that wisdom cannot be understood as a single ability or skill, but rather as the ability to orchestrate multiple talents to fit the demands of the occasion.

Taking these conceptions above as a starting point is illustrative. Like other talents, wisdom involves *exceptional* performance in the domain to which it is applied (life planning, life management and life review). Like other talents, those who attain high levels of wisdom often embody a profile of person characteristics and experiences that support their expertise. These clear analogies between giftedness and wisdom suggest the fruitfulness of using approaches taken in one field to investigate the other, and there is some methodological overlap. For example, nomination of wise or gifted people followed by careful study of these individuals is an approach taken in both areas with rich results (Csikszentmihalyi et al., 1993; Baltes et al., 1995). Other kinds of methodological borrowing might be interesting for researchers in both contexts. Importantly, the roles of mentoring and motivation in talent development have been, arguably, more investigated than in the case of wisdom, at present (see, e.g. Bloom, 1985; Subotnik & Arnold, 1993).

*Additional similarities and differences: looking at interventions.* As gifts with high relevance for societies, interventions to enhance the realization of gifted children's potential and interventions to improve individuals' wisdom-related knowledge and judgment have been of considerable interest. Interventions for gifted children can be loosely divided into acceleration, in which children are permitted faster movement through the traditional educational system, and enrichment, which involves additional educational experiences aimed at providing gifted children with a more challenging and elaborated environment (Southern, Jones & Stanley, 1993; Moon & Feldhusen, 1995). The latter often involves specific training (e.g. scientific method, library skills, etc), and a focus on additional and more elaborative exposure than the typical classroom environment. This is analogous to the two interventions we have employed to enhance wisdom-related performance in our own work.

In line with the idea of wisdom as a meta-talent, however, our interventions have focused on changes in the performance context more than on changes in the specific contents participants engaged with. Specifically, in one study, imagined or actual discussion with a trusted partner prior to responding to a wisdom dilemma enhanced wisdom-related performance substantially. This enhancement was presumably due to the more elaborative and comprehensive 'search' of the

person's existing knowledge, aided by the other person's actual or imagined dialogue and the increased perspective-taking provided by considering another person's viewpoint (Staudinger & Baltes, 1996). In another study, a specific criterion, value relativism, was the focus (Böhmgig-Krumhaar, Staudinger & Baltes, in press). A mnemonic strategy was adapted for use in cueing consideration of cultural variability while thinking about a wisdom-related dilemma, and participants trained with this strategy not only received higher scores on value relativism, but also higher scores on rich factual knowledge and lifespan contextualism as well. This latter finding is in line with the idea of providing gifted students with specific skills in research in order to enhance their ability to learn independently (Southern et al., 1993). Participants provided with a specific method of accessing knowledge about other cultures were able to apply this method to different dilemmas.

Despite the similarity of giftedness research and wisdom research at the conceptual, basic research method, and intervention level, at this point some fundamental differences between these two bodies of research must be noted. In our conceptualization, wisdom is conceived of as time-transcendent in nature and pertaining to life, rather than specific domains of performance. Examinations of the cultural and historical literatures on wisdom suggest that cultures display much consensus about wisdom (Assmann, 1994; Baltes, in preparation). Giftedness, by comparison, is often explicitly held up as a cultural construction (see, e.g. Sternberg & Davidson, 1986; Tannenbaum, 1986; Csikszentmihalyi et al., 1993). Further, ideas about giftedness often center around a specific ability in a structured and well-defined domain, although empirical investigations often focus on individuals with talents in multiple such domains or individuals with very high general intelligence (e.g. Csikszentmihalyi et al., 1993; Alexander, Carr & Schwanenflugel, 1995; Robinson & Clinkenbeard, 1998). The domain of wisdom is by contrast broad, ill-defined and ill-structured (Baltes et al., 1992). While gifted intervention research seeks to identify the most talented people in a domain and to ensure the fruition of their ability, in our own research we have sought to enhance the potential of normal individuals who were not identified because of specific talents. Perhaps most critically, wisdom is conceived of as the integration of knowledge from various domains (Baltes & Staudinger, 2000). In sum, wisdom cannot be purely treated as a kind of gift for knowledge about life; such an equation might lose the wholistic, integrative aspect of wisdom. From our view, it is better to think of wisdom as a meta-talent. Wisdom is the kind of expertise that allows individuals to maximize their own gifts or to give insightful advice to others about how to do so. That optimization process will draw not only on gifts within a specific domain, say, a particular talent,

but also on knowledge and abilities in many other domains.

*Giftedness as Superior Ability Influencing the Development of Wisdom: Primary Effects*

Does being gifted or talented in some specific domain, such as mathematics or science, contribute to wisdom-related knowledge and judgment? Answering this question requires direct empirical evidence that doesn't exist. However three competing predictions can be made based on existing literatures, and taking high IQ performance as the indicator of giftedness. We do not mean to suggest that high IQ is the only type of giftedness there is, but it may be the best-studied form of giftedness at present.

The first two hypotheses are simply competing predictions. Notions of wisdom as a balanced integration of intellectual and personality resources imply that an imbalance towards intellectual superiority (intellectual giftedness) might actually make wisdom more difficult to achieve. On the other hand, the idea that 'good things go together' might suggest that high intellectual ability would be a facilitator of wisdom-related performance. In fact, some of the very strengths of gifted children have been argued to come with specific vulnerabilities, related both to possessing high ability and to the experience of being labelled gifted (see, e.g. Webb, 1993). Such vulnerabilities might be taken as evidence for the idea that wisdom and intellectual giftedness are somewhat at odds with one another. The general picture of gifted adolescents, however, suggests that they are normal to above-average on most personality and self-concept measure that have been used (Perleth & Heller, 1995; Robinson & Clinkenbeard, 1998). What about good things going together? In a study we conducted, an array of positive intellectual, personality, and interface characteristics (those in between personality and intelligence, like creativity and cognitive style) predicted better moral reasoning performance and better wisdom-related performance, supporting the 'good things go together' idea at least within the domain of intraperson factors (Pasupathi & Staudinger, in press).

Of course, it might also be more complicated than simple facilitative or detrimental effects. The ontogenetic model implies that interactions among several different positive qualities are needed to produce peak levels of wisdom-related knowledge and judgment. Thus, high intelligence paired with the motivation to find out about life might be a powerful enhancer of wisdom-related performance. High intelligence without the necessary personality or motivational qualities might be irrelevant to wisdom-related performance. This may be why high intelligence does not seem to unequivocally provide unique benefits for wisdom-related performance, whether in our own work (see, e.g. Staudinger et al., 1997; Staudinger, 1999) or indeed, in work employing other conceptions of

wisdom (e.g. Labouvie-Vief et al., 1989; Kitchener & Brenner, 1990). Lastly, our own prior work does support a 'threshold' model of the relationship between fluid IQ and wisdom-related performance (see Staudinger 1999), that is, the relationship between wisdom-related performance and fluid IQ is neutral above a threshold value. Below that threshold, the two are positively related. A similarly discontinuous relationship might be evident for extremely high levels of intelligence, that is, at very high levels of intelligence, a relationship between intelligence and wisdom may emerge that is not like the relationship we observe in samples of normal intellectual ability.

The above discussion related primarily to the idea of intellectual giftedness. In other work, we have been able to show relationships between creativity and wisdom (Staudinger et al., 1997) and between moral reasoning and wisdom (Pasupathi & Staudinger, in press). As mentioned in the opening of this chapter, some conceptions of giftedness provide explicit domains of talent that can be seen as overlapping with wisdom; clearly, for those interested in peak human potential of all kinds, here is a rather open research agenda.

*Giftedness as a Life Experience that can Result in Wisdom: Secondary Effects*

Considerations of specific life experiences in the development of wisdom often highlight crisis-like, existential situations. But the experience of being labelled as gifted can be a very profound and far-reaching event for a child. Such an experience places the child apart, separate from others, and gives the child special status, which may be viewed positively or negatively by the surrounding society. As an event with such profound possibilities, being labelled gifted is an experience which may be 'mastered' or failed. In fact, there is some very limited evidence that being labelled gifted can create its own set of problems (Webb, 1993). Gifted adolescents in one study did react more negatively to failure, with more irrational beliefs, negative affect, and physiological stress, than did high achievers who were not labeled gifted and a randomly selected group of same-aged students (Roberts & Lovett, 1994). But the time between being labelled and this kind of assessment of psychological functioning may be critical; as a difficult life event, being labelled as gifted very likely requires some time for children to adapt to their status.

The experience of being labelled a gifted child may provide the opportunity for insight about relations between individuals and groups, experiences of separateness, even in some cases prejudice and stereotyping. Such labelling could also lead to a sense of being privileged and of owing a debt to society, as illustrated in the narratives of highly generative adults studied by McAdams and his colleagues (McAdams et al., 1997). Whether a child gains such insight from the

experience is likely to depend on many other factors, including the responses of caregivers and mentors, the child's own proclivities, and whether being labelled gifted has noticeable consequences at all in that child's particular context. But the examination of more diffuse and long-lasting experiences in considering pathways to profound life insight might prove very interesting.

### Conclusions and Outlook

We have suggested considering wisdom as a meta-talent, which acknowledges both similarities and differences between our conception of wisdom and existing conceptions of giftedness and talent. Wisdom-related knowledge and judgment, and by extension, wisdom itself, show non-linear, idiosyncratic paths of development over the lifespan. Whether a particular individual increases in wisdom-related knowledge and judgment depends on a constellation of factors, including everything from their own genetically constituted temperament to chance experiences and supportive contexts that help them gain insight about themselves and their worlds. There is little evidence for linear upward progressions with increasing age after adolescence, and little evidence for any decreases in performance after adolescence as well.

Giftedness researchers and those investigating wisdom and wisdom-related performances face similar difficulties in some ways. For example, identifying individuals who are qualitatively different than average based on largely quantitative indices remains a problem (for a discussion in relation to giftedness, see Gagné, 1993). Although normative (standard deviation based) approaches are often employed (e.g. we select the top 15 to 20% of individuals in our own work to examine what we refer to as wise performance), such approaches are only approximations of the qualitative distinctions we are often theorizing about. Another is trying to avoid a trait-like approach. Although our model focuses on wisdom-related knowledge and judgment, rather than on the identification of wise people per se, that assessment is necessarily made at the level of individuals. Similarly, although giftedness researchers would like to focus on gifted performances, the literature, for historical and pragmatic reasons, often focuses on gifted individuals (Jackson & Butterfield, 1986). In addition to these common methodological hurdles, juxtaposing giftedness and wisdom may suggest interesting and fruitful new directions for empirical inquiry. From a societal viewpoint, wisdom, like other important societal resources, is certainly a gift worth developing in all individuals, to the extent possible. How we encourage the development of wisdom is a question we psychologists have only begun to ask.

# Identification of Gifted and Talented Youth for Educational Programs

John F. Feldhusen<sup>1</sup> and Fathi A. Jarwan<sup>2</sup>

## Introduction

Gifted and talented youth are major national resources. With supportive and nurturing parents and high level and challenging educational services they can become the professionals, artists, care givers, and leaders of our nation and the world. Appropriate parenting and education are also needed to help them develop all of their human potential and lead rich and satisfying lives.

Meeting the needs of gifted and talented youth in the family and school begins with their identification as especially able individuals and includes assessment of their special aptitudes, talents, and interests. Educational programs and curricula that are general in nature and offer enrichment experiences to all identified youth are far less effective than programs that address specific talents and interests. The needs of mathematically precocious youth are far different from the needs of artistically or verbally talented youth. Appropriate curriculum and instruction recognize both the nature and level of gifted students' talents and aptitudes.

As a prelude to identification and assessment of gifted and talented youth it is essential that parents and educators have clear conceptions of the nature and manifestations of giftedness and talent. This means definition of terms and the relationships among them; giftedness and talent are not simply scores on tests and/or rating scales. They are descriptors of complex abilities as interactive components of human behavior that develop throughout the lifetime of gifted individuals; the major growth periods, however, are childhood and adolescence. We will address the conception of abilities, gifts, and talents at length in this chapter.

Once conceptions and definitions of giftedness, aptitude, and talent are delineated, the next task is to devise methods and procedures for implementing them in work with precocious youth. This means defining the goals of the identification program, the target popula-

tion. Will it focus on a few particular talents or a broad range of abilities? What tests, rating scales, behavioral observations, or product evaluations shall we use? How will the data we gather be synthesized or summarized to arrive at selection judgments? How will we assess specific talents and interests? How do we effect the transition from data or profiles to actual classroom experiences and family support? These are the critical questions we will address in this chapter with a view to paving the way to educational services and family support that help gifted and talented youth realize their full potential and achieve the highest levels of expertise, artistry, or professional contribution to society.

We will begin with a review of conceptions of giftedness and talent.

## *Conceptions of Giftedness and Talent*

General intelligence has served as the major representation of intellectual ability during most of the twentieth century. Beginning with the work of Binet (1902) in France, Spearman (1927) in England, and Terman (1916) in the United States, the metaphor of intelligence as the nexus of mental abilities grew to be the salient psychological construct representing human cognition. While the factor analyses of Thurstone (1938) and Guilford (1967) began to identify components or factors of intelligence, the concept of general intelligence represented by the IQ continued and still continues to hold sway in much of psychology and education as well as the practical worlds of business and industry.

The course of development in most scientific fields is from broad to ever finer and more detailed analyses. After decades of medical research we now delineate many specific forms of cancer and in clinical psychological research many specific types of mental illness. We can better understand, control, and minister to phenomena by addressing components, as for example blood cells in the cancer condition called leukemia or specific areas of the brain in mental illness.

Beginning with the extensive work of Thurstone (1938), Cattell (1971), Guilford (1967), and others in

<sup>1</sup> Purdue University, USA. E-mail: FeldhusenJF@aol.com

<sup>2</sup> Noor-Hussein Foundation, Jordan.

E-mail: jubilee@go.com.jo

factor analyzing intelligence tests, a new conception of human abilities began to emerge, identifying specific factors of intelligence. Methods of factor analysis changed over time so that while Thurstone's analyses yielded a parsimonious set of six or seven major factors of intelligence, Guilford's analyses seemed to reveal over a hundred and possibly several hundred factors. Both Thurstone and Guilford also brought creativity factors into the realm of intelligence: Thurstone with 'fluency' and Guilford with an extensive set of divergent thinking factors.

The history of gifted education has witnessed extensive efforts in both theoretical and empirical areas to define the construct *giftedness*. Yet, there is little agreement among researchers and educators on a precise definition and measurement of giftedness (Horowitz & O'Brien, 1985; Janos & Robinson, 1985). The widespread disagreement is a result of varying and conflicting conceptions about the relationships among and definitions of giftedness, intelligence, and talent (Gagné, 1985; Feldhusen & Hoover, 1986). Hallahan and Kauffman (1982), however, argued that the reasons for disagreement are mainly due to differences regarding four issues: the range of skills and behaviors to which the term giftedness should be applied, the measurement of giftedness, the cutoff point above which a child is considered gifted, and the nature of the comparison group. In an insightful analysis of the term and the conception of giftedness Gallagher (1991) concluded that it is time to change our terminology because the term 'gifted' connotes unearned privilege and creates problems for students who are so designated. Recent research and theory development by Carroll, Sternberg, Gardner, Gagné, and others show the way to new and better terms and conceptions of superior ability.

#### *Carroll, Sternberg, Gardner, and Gagné*

During the last two decades of the twentieth century the work of four psychologists dominated the new analytical approach to human mental ability, intelligence, or cognition—Carroll, Sternberg, Gagné, and Gardner. These four and a host of other researchers sought to map out the terrain of human intelligence. Although their maps differ a great deal, their insights about human cognitive functioning have given us a better understanding of the intellectual processes underlying the general mental operation called 'intelligence'.

#### *Carroll's Three Stratum Theory*

The factor analytic tradition in psychology that sought to identify the components of human intelligence or ability reached its peak in the large factor analyses conducted by John B. Carroll on 461 data sets. Based on the empirical data and the factor analyses Carroll proposed (1996) a three-stratum theory of intelligence in which *g* or general intelligence supersedes all

intellectual functioning. Stratum II includes eight broad areas of ability: fluid intelligence (2F), crystallized intelligence (2C), general memory and learning (2Y), broad visual perceptions (2V), broad auditory perception (2U), broad retrieval ability (2R), broad cognitive speediness (2S), and processing speed (2T). Based on his factor analysis of 461 data bases, he goes on to specify 70 subfactors under these eight Stratum II abilities. They included, for example, five reasoning abilities under 2F; sixteen knowledge acquisition abilities under 2C; six memory factors under 2Y; eleven visual and imagery factors under 2V; fifteen auditory factors under 2U; nine creativity and fluency factors under 2R; four cognitive speed factors under 2S; and four processing speed factors under 2T. Carroll goes on to suggest that the abilities represented in these factors "refer to variations in individuals' capabilities to respond successfully to a class of tasks that differ in difficulty . . ." (p. 14). Among the 70 subfactors the reasoning, imagery, creativity, and fluency factors are especially relevant to our efforts to identify specific aspects of giftedness and talent.

#### *Sternberg's Triarchic Theory*

Sternberg (1985) proposed and elaborated a triarchic theory of intelligence that has become a major new theory in the worlds of education and psychology; the model is fundamentally an information-processing approach to human intellectual functioning. The three major parts of the model are metacomponents, performance components, and knowledge-acquisition components.

The metacomponents are essentially metacognition processes including: (1) recognizing problems, (2) clarifying problems, (3) planning, (4) creating strategies to solve problems, (5) mental representation of problems, (6) pulling together the cognitive resources needed to solve problems, (7) surveillance of problem solving, and (8) judging the adequacy or quality of solutions.

Knowledge-acquisition components are forms of intelligence in which new information is dealt with and committed to long-term memory. Selective encoding is sorting among all the information we encounter and deciding which pieces are relevant and useful in our intellectual operations. Selective combination is uniting pieces of information into integrated and more useful wholes. In essence it is "putting two and two together". Selective comparison is seeing relationships among pieces of information in long-term memory and new information in working or short-term memory.

Performance components are lower order or less complex forms of intelligence that serve to carry the metacomponential processes. They are often fairly specific pieces of knowledge or skills that are related to a problem being addressed. Again, we might see them as the particular mental skills needed to execute moves in chess, solve water jar problems, write poetry, or

solve algebraic problems. They constitute the working abilities we need to function well in a special domain of activity.

While we await good measures of all the components, it is clear that all of the metacomponents are specific abilities that can be assessed and nurtured by schools as the higher level thinking skills. The knowledge acquisition components deal with the learning and retention of information and the development of knowledge bases. The performance components represent specific behavioral skills that students need to function well in their particular domains of talent. The Sternberg abilities represent much more practical and applicable aspects of giftedness and talent than the Carroll factors; they can more readily be assessed and they point the way to specific curricular and instructional activities (Sternberg, 1997).

#### *Gagné's Differentiated Model of Giftedness and Talent*

The most well articulated theory of giftedness and talent development was first presented by Gagné in 1985. In the years following, Gagné has carried on a substantial program of research based on and growing out of the theory, and he has continued to refine the overall theoretical model of talent development. This model recognizes general or basic gifts but goes on to delineate how more specific talents grow out of environmental influences and interactions. The 'gifts' are the genetic endowments while talents are the product of the synergistic interaction of genetic predispositions with home, school, and the physical and social environments surrounding a child. In an extensive study of 2343 students in 88 classrooms Gagné (1993), using 42 talent descriptions and teacher and peer nominations, found substantial sex differences in the incidence of talents in the areas of creativity, cognitive abilities, socio-affective activity, physical prowess, academic talent, technical skills, artistic talent, and interpersonal functioning.

The theory proposes that there is a basic set of gifts that evolve into specific talents through the cognitive interactions that the child experiences with persons, events, environments, and chance factors. An emerging set of interpersonal factors in the realms of personality and motivation are also manifested and influence the course of talent development. Much of the influence on talent development derives specifically from learning, training, and practice. Gagné's research has focused a great deal of attention on delineation of fields and categories of talent. Since the theory is presented elsewhere in this volume, no further elucidation of it will be presented here. However, we wish to make clear that the theory is a major basis for current research, theory, and school practice in talent development (Gagné, 1997). The recent publication by Gagné (1999) of rating scales for self, peer, and teacher ratings of talents and the profile methodology devel-

oped by Kay (1999) make the model now a practical procedure for identification in school settings.

#### *Gardner's Multiple Intelligences Model*

Garner has revived and reconceptualized factors of human ability. Gardner's model of multiple intelligences (1993) is now recognized as the most popular and widely applied model of human abilities. The broad categories of (1) linguistic, (2) logical-mathematical, (3) spatial, (4) musical, (5) bodily-kinesthetic, (6) interpersonal, and (7) intrapersonal abilities or 'intelligences' as they are called are being used extensively to structure general school programs, gifted programs, and 'key' schools that serve as model programs. However, there is little evidence to show that they are being used to identify specific youth talents or to individualize programming for gifted and talented youth. Schools and teachers have embraced the model avidly as a guide to curriculum and instruction, yet there are few specific tests or assessment guidelines to identify precocity, giftedness, or talent in the seven domains. Nevertheless the model and the intelligences, preferably called 'talents' as Gardner, Walter & Hatch (1992) suggested, enhance both our conception of giftedness and identification of its component abilities.

The work of Carroll, Sternberg, Gagné, and Gardner has been influential in promulgating the concepts of multiple aptitudes, talents and abilities. While the field of gifted education often clings to a unitary conception of giftedness, the new work of these researchers is broadening our views of giftedness and should lead to totally new approaches to identification and assessment in programs for gifted and talented youth.

#### *Definitions of Giftedness and Talent*

An explicit definition of giftedness is considered by many authors to be a keystone for the development of programs for the gifted. It is important because of the close link that must exist between the definition and the identification system (Ward, 1983; Feldhusen, Asher & Hoover, 1984; Hoge, 1988). It is also important because of its relationship with program goals and curriculum offerings (Feldhusen, 1982). Finally, the definition adopted or developed by a school will determine in general terms who will be selected and who will be excluded.

Technically a 'gifted' child is one who scores high on an intelligence test or an academic achievement test and who has partially or totally inherited his or her ability. However, a 1993 policy report from the U.S. Office of Education, *National Excellence: Developing America's Talent* proposed that the term 'gifted' be used to denote mature achievement, not developing ability; that report also spells out all the types of abilities as talents. However, we argue that giftedness is basically genetic endowment that paves the way to the

development of specific abilities, aptitudes, and talents.

Talent is a specific ability within a domain of human activity such as art, music, mathematics, political science, drama, or literature. It may also be physical talent as in tennis, golf, or bowling. Some talents are broad as, for example, 'verbal' talent while others are narrow or circumscribed such as 'gun repair'. Individuals may have one or a number of superior talents; talents vary in level or proficiency. Most youth have some special talents but a relatively small number have superior talents.

### The Identification Process

Identification of youth talents often begins with a general measure of mental ability, intelligence, or achievement to determine a child's general level of precocity. The steps leading up to such testing may include teacher and/or parent observations of such behaviors as learning to read before entering school, early facility with numbers and arithmetic operations, oral-verbal fluency and extended vocabulary, ability to use logic in reasoning, or strong interests in science topics. Generally the child may show capacity to function well at age levels two or more years beyond his or her chronological age.

The initial assessment may also come about because the child demonstrates personal or social problems in addition to the precocity. Peer relations may not be going well, regular school activities may be rejected by the child, achievement in the form of classroom tests and teacher grades may be far under expectations, the child may be inattentive in school, and/or misbehaviors may even be exhibited. Assessment as a result of such problems may lead to a need to find alternative curricula and instructional methods to better serve the child.

Ideally the label 'gifted' is not ascribed to the child at this point nor at any time in the identification process. While schools try to avoid labeling children in either positive or negative ways, there is a special need to avoid the 'gifted' label because of its high genetic pretence, because it mistakenly communicates to the majority of children that they have no special gifts or abilities, because it may evoke negative peer reactions, and finally because it may communicate to the labeled child that he or she has superior ability and hence should not have to work hard in school.

Having determined that a child has superior ability or is precocious in school achievements, the next step is to determine a child's specific talents, areas of precocious achievement, aptitudes, or abilities. Children who are designated as 'gifted' are not superior in all forms and areas of ability; each has unique patterns of high achievement, aptitude or talent (Achter, Lubinski & Benbow, 1996). Efforts to meet their educational needs must be directed to their specific talent strengths, not to giftedness in general.

### Using Multiple Criteria

In almost every program and service for gifted and talented youth there is a limited number of openings and resources; the identification criteria are general conditions regarding eligibility for consideration or nomination. They function as a means of controlling the number of nominees or applications within a reasonable range. The use of multiple procedures for identification has been emphasized as a response to theories of human abilities which stress multiple factors (Gardner, 1991). It is important, however, to recognize that this approach does not necessarily guarantee making valid decisions. The quality and relevance of measures place limits on the reliability and validity of such decisions. The question to be raised, therefore, is not how many measures are used in the identification process, but rather what contribution each piece of information has to making valid decision or to serving specific objectives (Piirto, 1994). It is a waste of money, time, and effort to collect data that are not going to be used or are not contributing to more valid and reliable decisions.

A variety of data sources are suggested in the literature for the identification of academically gifted and talented children for special services (Feldhusen, Jarwan & Holt, 1993). The list includes standardized tests, school grades, rating scales, references, essay writing (Feldhusen & Baska, 1989), past accomplishments (Coleman, 1985), interviews, creativity tests (Torrance, 1984), and creativity inventories (Rimm, 1984). Feldhusen, Jarwan & Holt (1993) present comprehensive descriptions and evaluations of tests and scales they recommend for identification of generally gifted and specifically talented youth.

### Identifying Giftedness and Talent Among Special Populations

Identifying gifted students from special populations and identifying their specific talents has posed a challenging problem for professionals and educators in the field of gifted education (Feldhusen, Asher & Hoover, 1984; Bragget, 1990; U.S. Office of Education, 1993). Research on special populations in the past focused more on their deficits rather than on their strengths (Baldwin, 1985; Baum & Owen, 1988); however, an identification system should guarantee that no one who is qualified is overlooked. Frasier (1994) has carried out pioneering work on methods and procedures for the identification of general giftedness and specific talents among minority populations.

The National Association for Gifted Children's Committee on Special Populations (Jennings-Friedman, Richert & Feldhusen, 1991, pp. vi-viii), adopted a position statement relating to the definition and identification of special populations. The term is defined to include "groups who differ from those who have been traditionally well represented in school programs for the gifted" and it "can be applied to

children and young adults who are Black, Hispanic, Native American, Asian Pacific, rural, economically disadvantaged, handicapped, and female, as well as students whose gifts are in domains not traditionally recognized in school settings." The statement also indicates that typical instruments and procedures used to identify gifted students for special programs are often inadequate and insensitive to the unique qualities and characteristics of special populations. Ignoring the needs and special problems associated with identifying gifted/talented students from special populations also leaves the field vulnerable to charges of elitism and racism (VanTassel-Baska, 1989).

It is imperative, as we argued earlier, that identification of giftedness and talent among special populations focus both on the possible presence of superior general abilities, *g*, or general intelligence but also on emerging talents or capabilities. Feldhusen (1995) has proposed that those talents may be academic or intellectual in nature, artistic, in business and technical fields, and/or personal-social in nature. Superior intelligence should never be the sole or pre-requisite criterion for identification and eligibility for programs.

#### *Handicapped Gifted*

The term 'gifted handicapped' refers to children who have two sets of characteristics: giftedness or talent and disability (Clark, 1992). They are impaired by one or more specific conditions that include: learning disability, hearing impairment, visual difficulty, neurological disorders, emotional problems, and motor disabilities (Whitmore & Maker, 1985; Yewchuk, 1985). Obstacles to identifying disabled children as mentally gifted or talented include: stereo-typical expectations, developmental delays, incomplete information about the child, lack of challenge, and lack of appropriate tests or rating scales. It is also a problem in many schools that non-handicapped children qualify quickly and easily for all the available program openings, especially when the program is limited to generally 'gifted' youth, and thus no effort is made to search for giftedness or talent among youth whose handicaps or minority status hide their gifts or talents.

#### *Gifted Underachievers*

'Gifted underachiever' is another category of gifted special populations. Whitmore (1980) defined 'underachievement' as "performance judged either by grades or achievement test scores, or both, that are significantly below the student's measured or demonstrated potential for academic achievement" (p. 168). Although there are many different definitions (Seeley, 1989), the underlying concept is that there is a discrepancy between potential and actual performance (Mooij, 1992). The problem of gifted underachievers is simply that they are often not identified for any special services because they do not meet the criteria for selection which require high achievement or perform-

ance (Boyd, 1990). If the popular conception that many outstanding women and men were poor achievers or indifferent scholars as children is correct (Reynolds & Birch, 1977), and if the magnitude of the problem is huge as has been estimated (Whitmore, 1980), then identification of gifted underachievers should be one of the important concerns reflected in systems for identifying gifted students. Rimm (1995) has been a leader in efforts to identify and help gifted students who are underachieving in school; she offers comprehensive guidelines for assessment of the underlying achievement problems and for corrective educational therapy.

#### *Gifted Females*

Gifted girls and women are considered a 'minority' group or special population because of their underrepresentation in higher levels of schooling, professions, and achievement in mathematics and science (Gallagher, 1988; Callahan & Reis, 1996). Sex differences on the mathematics portion of the Scholastic Aptitude Test (SAT-M), were found in the first talent search of Johns Hopkins University (Stanley & Benbow, 1983). Fewer girls than boys scored at high levels of mathematical reasoning ability. At the high school level, the authors found sex differences favoring males mathematics course enrollment, performance on the SAT-M, and taking of, and performance on, mathematics achievement and Advanced Placement Program Examinations. Also, in the Study of Mathematically Precocious Youth (SMPY), males performed better than females on achievement tests measuring knowledge and understanding of biology, chemistry, and physics.

Kerr (1997), a leading scholar in the study of gifted girls concluded that the problems of gifted girls in the realm of gifted education are in both the identification process and in educational programming. She offers insights for increasing equity and opportunities for gifted girls in the classroom and practical guidelines for enhancing achievement behavior, social self-esteem, and exploratory behavior of gifted girls.

#### *Minority and Disadvantaged Student*

Frasier (1994) developed a 'culture-specific' assessment system that evaluates "the intelligence of each person in relation to others who come from similar socioeconomic backgrounds and who have had the same opportunity to acquire the knowledge and skills needed to answer questions on an intelligence test designed for an Anglo-American society." She also recommends using standardized tests that allow for culturally different manifestations and interpretations of intellectual ability. Frasier cited many references regarding the inappropriateness of traditional intelligence tests for black students.

VanTassel-Baska (1998) argued that minority and disadvantaged student are the most neglected of all the

school subpopulations and especially African-American students. She suggests that the identification process should focus on special attributes of minority subcultures, use non-traditional measures, and search for creative and psychomotor talents; and programs should address issues of motivation and related non-cognitive skills. She concludes by delineating a number of effective intervention tactics especially focused on curricular adaptations.

From the review of literature on identification of gifted students from special populations (Frasier, Garcia & Passow, 1995) we conclude that the problems associated with identifying and serving these gifted students are major concerns for both educators and policy makers. A defensible program for the gifted must deal with the diverse talents and abilities that characterize different ethnic and cultural groups (Frasier & Passow, 1994). A variety of objective and subjective assessment data should be used to ensure the discovery of talents existing across and within populations and sub-populations of children.

### Phases of Identification

A sound identification system typically is carried out through a series of steps. The order and sequence of steps, clarity of objectives, purposefulness of each component, and the modifiability of the system are important foundations for a defensible identification system. The number of steps and the purpose of each step is dependent upon the nature of the program for the gifted and the talent areas it strives to serve. Is the program restricted to a school building? Is it a program serving a school district or statewide population of students? Does it address academic, artistic, vocational-technical, and personal-social talents?

### Application

Many programs for gifted and talented youth begin with an announcement of the program, descriptions of what will be offered, and detailed criteria for admission or acceptance. Youth and their parents may then decide to submit an application. The identification criteria often include test scores, letters of evaluation, and rating scales to be completed. Often the youth-candidates are asked to write a letter setting forth why they want to be in the program and why they believe themselves to be qualified; an admissions committee then reviews applications, and using the criteria as guides, selects youth for the program. Often such programs and identification systems make little pretense as to the levels of giftedness nor to the specific talents of the youth who are selected.

### Screening and/or Preliminary Assessment In School Program

Screening or preliminary assessment is often the second step in the identification process. Many activ-

ities are carried out during this process such as: getting information from school records, collecting and categorizing information from nomination forms and referrals, testing, synthesizing information, and selecting students for further testing. The ultimate function of screening activities is to find youth who have superior talent potential. The following guidelines are suggested to achieve this goal: (1) use multiple criteria, (2) train staff on the identification procedures, and (3) use reliable and valid screening tests and rating scales. The screening process should and probably will produce more students than will ultimately be selected for the program.

In addition to existing school records and group test scores, nominations from teachers, counselors, peers, parents, and the students themselves can be used. Setting cutoff points on some screening measures should not lead to ignoring strong evidence from other sources. In school practice it is common to have 10–20% of the school population in the initial screening pool, especially if a broad definition of giftedness is used, including academic and artistic talent. Inclusion in the initial screening pool, not exclusion, is recommended (e.g. Feldhusen, 1989; Clark, 1992). Borland and Wright (1994) suggested two practices to serve this purpose: (1) set low cutoff points on screening measures, and (2) include every student who meets the cutoff score on any one screening measure. It is extremely important to follow Borland's suggestions if one is searching for nominees among special populations.

Effectiveness and subsequent efficiency of the screening process can be substantially improved by providing adequate training for all staff who participate in the screening process. Hoge and Cudmore (1986) reviewed the literature on teacher accuracy in identifying gifted students and concluded that the validity of teacher judgments or ratings can be improved substantially through appropriate training. Such training should include clarification of the processes of screening and identification, communication of the overall goals of the program, and tryouts of all the forms and procedures. Finally, the tests and rating scales should be of the highest quality obtainable. Evaluation information about tests is quite readily available in the *Mental Measurement Yearbooks*. Nomination forms and rating scales, however, are often locally produced with little or no attention to their validity or reliability; they should be used therefore with extreme caution.

### Data Synthesis

An enormous number of research studies and writings have argued strongly and persuasively in support of using multiple selection criteria (Richert, Alvino & McDonnell, 1982; Feldhusen, 1989; McLeod & Copley, 1989). However, very few studies have discussed the emerging problems of: (1) how to reduce and combine data in a defensible way that facilitates

selection decisions, and (2) what practical procedures need to be used in validating those decisions.

It is important to recognize that the use of multiple selection criteria does not necessarily guarantee making valid decisions. The quality of the identification measures and the manner in which the data are synthesized and interpreted is critical in making valid selection decisions. Therefore, as stated earlier, the question to be raised is what contribution each measure makes to the validity and efficiency of the system. Three methods will be discussed: (1) standard score method; (2) multiple-cutoff method; (3) multiple regression method.

#### *Standard Score Method*

If the goal of identification is to find the 'all-purpose gifted child', the most appropriate metric of psychological measurement is the standard score system (Lauer & Asher, 1988). The use of the basic standard score scale (z-score) or any of its derivatives (e.g. t-scores) achieves comparability of means, dispersions, and the form of distribution (Guilford & Fruchter, 1973). Equality of units is an important characteristic of standard-score scales.

The standard score metric can also be used to get a composite score for several identification measures. For example, while it is indefensible to combine measures from mathematics, verbal ability, and artistic talent to select students for a program stressing science and technology, the standard score method can be used after selecting appropriate measures such as science achievement test scores, ratings by teachers of students' technological aptitude, and quantitative aptitude from a cognitive skills index. Here the measures may all have theoretical relevance to the program goals in science and technology; however, the matrix method fails completely to identify youths' specific talents.

#### *Multiple-Cutoff Method*

According to this method, a minimum score is set for each measure in the identification system; students who have scores equal to or in excess of all the minimums are selected for the program. Any student who fails to meet the standard on any one measure is not selected. The rationale underlying this method is that high aptitude or ability in one area does not counterbalance low aptitude or ability in another (Hills, 1971). The major problem with this method is that the cutoff points are often arbitrarily set without adequate evidence of the validity of the measures or without any reference to the criterion measure of success in the program. Also, as the measures become less reliable and highly correlated the method becomes less and less defensible for selection (Lord, 1962). In actual practice, the cutoff points are often established on the basis of external determinants, such as the number of

applicants, the number to be selected, and the distribution of scores on one measure.

#### *Multiple Regression Method*

Multiple regression is a correlational method that makes it possible to take several identification scores and find a single composite correlation with measures of student achievement later in or at the end of a program. It serves to test the predictive power of the identification scores in relation to student outcomes or achievement in the program. The multiple regression method is based on the assumption that synthesis of the identification data should lead to relatively accurate prediction of student success in the program. The question of how effective and efficient the system is, should be carefully tested and validated against stated criteria of success in the program. The underlying conception behind the use of measures in educational selection is that they have predictive validity (Cronbach, 1970; Hoge, 1988; Feldhusen & Baska, 1989), that is that they select students who will be able to meet the goals of the program and exclude students who would fail to achieve the goals. For such an assumption to stand, "data must be collected which indicate that the instruments used to identify students do indeed predict success in the gifted program" (Feldhusen, Asher & Hoover, 1984, p. 151). Correlational and multiple regression analyses are appropriate means for dealing with the problems of synthesizing data and validating identification systems. The major advantages of this method are:

- (1) The use of multiple regression implies the need for establishing solid relationships among three major components of any well-structured program for gifted and talented youth: (a) selection measures (predictors), (b) the instructional program, and (c) measures of outcomes (criteria).
- (2) Multiple regression yields the most accurate predictions, and is never improved upon by using additional methods.
- (3) Multiple regression provides an unbiased selection index that is a best weighted linear combination of identification criteria with minimal error of prediction.
- (4) Regression equations have the advantage of the compensation principle over the multiple-cutoff method. The simultaneous processing of all measures in the regression equation allows a high score on one measure to compensate for a low score on another. This principle is very important for the inclusion of some students who score very high on one measure but who fail to meet the cutoff on another (Jarwan & Asher, 1994).
- (5) The relative importance of each selection measure in the regression equation can be determined using beta coefficients when all measures are stated in standard score form. The measures with beta

coefficients near zero can be dropped from the selection system, and the cost of the identification process can be reduced.

- (6) Multiple regression can be run using available computer statistical packages.

#### *Identifying Specific Talents*

The next major task in the identification process is to identify the specific talents, aptitudes, or abilities of prospective students so that the programs and curriculum can be tailored to students' specific needs. Feldhusen (1999) proposed that talents should be assessed in the areas of academics, arts, vocational-technical skills, and interpersonal-social activities. The vocational-technical area has also been incorporated into the talents domain by Bals (1999) and the arts by Baum, Owen & Oreck (1996).

A number of excellent diagnostic instruments for identifying giftedness and talent are described in detail by Feldhusen, Jarwan & Holt (1993). They especially focus on cognitive tests of intelligence, aptitude and school achievement that are useful in academically oriented programs.

Several sets of diagnostic rating scales are also useful such as *Scales for Rating The Behavioral Characteristics of Superior Students* by Renzulli et al (1997), and the *Academic Talents Rating Scales* and the *Vocational-Technical Rating Scales* by Feldhusen, Hoover & Saylor (1997). The ten Renzulli scales assess strengths or talents in art, music, drama, learning, leadership, motivation, expressiveness and precision in communication, creativity, and planning. The *Academic Rating Scales* are used to assess specific talent in mathematics, science, social studies, English, and foreign languages. Finally the *Vocational-Technical Rating Scales* focus on talent in agricultural studies, business, shop-mechanical, and social-interpersonal activities.

Gagné (1999) has also published new rating scales to identify multiple talents through ratings by peers, teachers, and self assessment for cognitive abilities, academic talents, social skills, physical-sports abilities, and technological and artistic talent. All of these rating scales have been carefully developed and have good technical qualities including evidence of reliability and validity. However, the problems of identifying talents in special populations should be addressed specifically. Plucker, Callahan & Tornchin (1996) did just that using Gardner's multiple intelligence framework (Gardner, 1993) and Udall & Passe's (1993) *Multiple Intelligence Assessment Technique*. Observations, performance-based activities, and teacher rating measures were adapted for the project. They found some good evidence of reliability in the assessments and limited evidence of convergent and discriminate validity of the scales.

Identification of talents in the arts has been addressed by several researchers, notably Piirto (1994),

Haroutounian (1993), and Clark & Zimmerman (1994). Programs for the gifted and talented should and can identify youth talents in the arts and provide individually appropriate services to them.

#### *Selection-Placement*

In many programs for talent development there is a fixed number of openings and limited resources; therefore, the ultimate goal of this phase is to select students who show the greatest talent potential and need for the service. Further testing may be required to make more valid decisions and especially to make sure that students from special populations have equal access to the programs. Individual tests, group tests, essays, auditions, and interviews are possible sources of additional information that might be relevant to program services.

The final phase of the identification process is placement of students in the program or service. Ideally there should be more than enough openings so that students who may be borderline cases or from special populations can try out in the program for a time to determine if they can perform well and profit from participating. The ultimate final stage of the identification process comes later when empirical tests of performance in the program or service are carried out to determine if those who were picked perform up to expectations and profit from the program services (Jenkins-Friedman, Richert & Feldhusen, 1991). The program services should, of course, be tailored to address students' specific talent strengths and interests. Kay (1999) and Feldhusen (1999) have both developed profile methods for delineating the specific talents of students as a prelude to selecting appropriate services, activities, resources, and experiences that will minister most effectively to the specific talents of individual students.

#### *Summary*

A special program for gifted or talented students should provide more advanced, rigorous curriculum experiences to satisfy intellectual needs, which are not addressed in regular classes. Thus, selection strategies must be focused on finding those youths who need and can profit from the advanced learning experiences and excluding those who would not benefit from it or who would fail in the program. An efficient identification system can play a role in meeting the requirements for making selection decisions not only on the basis of 'who is best' but also 'who is qualified'. It is important for administrators of programs to be as clear as possible in adopting a selection strategy that assures that those who are selected meet minimum standards for success in the program. Decisions regarding minimum standards are influenced by the selection strategy and the orientation of the program. Empirical evidence and/or professional judgment can be used to make a sound decision.

Over a period of years we have reviewed, analyzed, and critiqued identification processes in gifted education (Feldhusen, Baska & Womble, 1981; Feldhusen, Asher & Hoover, 1984; Feldhusen, 1991, 1992). Hoge (1988, 1989) also critiqued practices and the literature on identification of the gifted (1989). He concluded that there is a need to be explicit in defining the giftedness constructs and component traits, talents, and aptitudes. Definitions should be derived from theory concerning human abilities in general and superior ability in particular. Then the specific identification or selection procedures should be derived directly from the definition and supporting theory. Finally, there should be substantial efforts to verify or validate the identification system empirically.

Our recommendations then are as follows:

- (1) Identification processes in gifted education should be based on the best current conceptions and theories of human aptitude, talent, and abilities.
- (2) Test instruments and rating scales with established reliability and validity should be selected for use in the identification process.
- (3) Identification should be viewed as an ongoing process. One should not conclude that assessment at one point in time, even with multiple tests, finally and unequivocally identifies the gifted child. Giftedness and talent are emerging abilities calling for repeated evaluation as youth mature.
- (4) Labeling children as 'gifted' should be avoided; it is preferable to regard the process as selecting children for programs or services. Implicit labeling of children who are not selected as 'ungifted' is also a serious problem, especially when the labeling process openly labels others as 'gifted'. Ideally a good program should help all youth to identify, understand, and develop their talents, whatever the initial level, to the highest level possible.
- (5) Identification should always be diagnostic in nature, identifying strengths, aptitudes, and talents as well as problems, weaknesses, and needs.

The concepts of 'general giftedness', 'gifted child', and 'gifted education' are no longer tenable in light of emerging research and theory on human abilities, psychometric shortcomings, and social offensiveness. Decades of research on factors of human intelligence as well as more recent research on human talents lead to a broader conception of human abilities as embracing not only academic-intellectual ability, as has been the focus of the 'gifted movement', but also talents in the arts, personal and social capabilities, and vocational aptitudes. The work of a number of researchers, notably Ericsson (1996), also lead to a much greater conception of plasticity in the development of human abilities. While Plomin (1990), Bouchard (1994), Wachs (1992) and others delineate the genetic potentials and limits in human abilities, it is also clear that

emerging talents, aptitudes, and abilities are to a great extent products of learning experiences. Thus, the field of gifted education must heed the warning of a report from the U.S. Office of Education (1993) that the term 'gifted' no longer characterizes well the children who are subjects of our interest and that we should shift our view and effort to a broader range of talents in children.

Thus, the task of identification shifts from a search for the gifted few to assessment of the talent strengths and aptitudes of all students, and to identification of high level talent potential among those who are especially precocious or advanced in their talent development. None of what has been presented in this chapter implies that all children are 'gifted' in the traditional sense of that term, but it is becoming clear that relatively large numbers of youth demonstrate one or more potential talent strengths and a smaller but significant number demonstrate high talent potential which if identified and nurtured may lead to high level creative achievement in adulthood.

# Dynamic Assessment of Gifted Students

Lannie Kanevsky<sup>1</sup>

## Introduction

Dynamic assessment is an interactive methodology designed to evaluate latent learning potential, i.e. a learner's ability to benefit from instruction (Sternberg, 1986). The dynamic aspects are evident in its format (pretest—teach/learn—post-test) and its commitment to nurturing and measuring change. It has been used extensively in work with students who are young, culturally different, disadvantaged, or learning disabled (Lidz, 1987, 1991; Haywood & Tzuriel, 1992; Hamers, Sijtsma & Ruijsenaars, 1993; Swanson, 1994), yet only recently entered into identification procedures and research in gifted education.

Traditional, 'static' intelligence tests have been found to underestimate the intellectual potential of culturally, linguistically, and socio-economically different children (Skuy, Kaniel & Tzuriel, 1988; Tellegen & Laros, 1993; Frasier & Passow, 1994). The individuals' test scores were reduced by gaps in knowledge rather than ability because they had not had equivalent opportunities to learn information derived from mainstream culture represented in the tests' items. This bias has contributed to the disproportionate representation of minority learner groups in educational programs requiring cut-offs on test scores: programs for developmentally delayed students and programs for gifted students. This situation stimulated a search for alternatives that more accurately assessed the dynamic *processes* that contribute to intellectual development rather than products based on experience.

Conceptions of giftedness or intelligence emphasizing potential (e.g. Tannenbaum, 1983) also create the need for "techniques which assess not only current manifest ability, but ascertain what the children concerned might be capable of" (Skuy et al., 1988, p. 91). The influences of socio-cultural theories of development bring with them a focus on the role of social interaction in the development of higher intellectual functions. Keeping in mind that the best predictor of any criterion is a sample of that performance (Anastasi & Urbina, 1997), it becomes essential to

assess processes, like learning, that contribute to talent development.

Bolig and Day (1993) have summarized the ways in which dynamic assessments address concerns related to traditional intelligence tests:

(1) Dynamic assessment allows for the fact that children with identical competencies on static tests may profit differentially from instruction.

(2) Dynamic assessment provides information that could be used in the creation of intervention programs to facilitate the child's development.

(3) Dynamic assessment techniques were developed to overcome biases against minorities induced by traditional intelligence tests.

(4) Dynamic assessments focus on what children can learn (rather than what they do not know) and can be tailored to a child's unique personality and/or preferred learning styles.

(5) Dynamic assessments are domain specific indicators of learning ease, not general measures of ability (e.g. IQ tests) (p. 111–112).

The majority of dynamic assessment research involving high ability children has investigated its potential utility in identification of giftedness; other work has explored ability-related differences in the nature of learning. Following a brief description of dynamic assessment and its roots, these two lines of research will be examined. The chapter closes with a discussion of issues, trends, and recommendations.

## Static and Dynamic Assessments

The broad view of psychological assessment is of a conceptual, flexible, problem-solving process for "understanding individuals for defined and useful purposes" (Tallent, 1992, p. ix). Tests can be part of the process, however they provide a restricted view of an individual's potential. Both static and dynamic measures are necessary when generating a diagnostic profile for a student (Vygotsky, 1978; Day, Enghardt, Maxwell & Bolig, 1997) and both can make valuable contributions to identification and education.

Traditional measures of intelligence are characterized as static, normative, and standardized (Haywood, Brown & Wingefeld, 1990). They are considered static because they are designed "to assess

<sup>1</sup> Faculty of Education, Simon Fraser University, Burnaby, British Columbia, Canada. E-mail: kanevsky@sfu.edu

performance at some specific moment, with no attempt to change that performance" (p. 411); normative because a child's score is compared to that expected to be earned by an 'average' individual in the norm group; and standardized because standard procedures used to administer the tests and interpret the scores have been followed. Traditional intelligence tests can answer questions related to a child's relative strengths and weaknesses when compared to age or grade-level norms; a score reflects what an individual knows as a result of past experience.

In contrast, dynamic measures of learning potential involve supporting the child's efforts to perform the 'test' task. They are most "concerned with the different ways in which individuals who earned the same [static] score achieved that score" (Palinscar et al., 1991, p. 76). The assessor leaves the session with information regarding the amount and nature of improvement that took place, and the assistance needed for the child to perform the task independently (Brown & Ferrara, 1986). The many versions of dynamic assessment share a commitment to assessing learning-in-process by activating the complex relationship between teaching, learning, and assessment. Considering all three in unison provides a "prospective" view of children's potentials while they are learning from others, and that information can play a key role in multidimensional identification processes and educational planning.

### Foundations of Dynamic Assessment

The modifiability of intelligence has been a recurring theme in psychology. Binet (1909), Dearborn (1921), and Henmon (1921) were a few of the early researchers who argued that intelligence was modifiable and that learning capacity ought to be considered a prime index of intelligence. Binet even developed activities he called 'mental orthopedics' to improve learning skills and test performance (Snow, 1990). This was followed by decades of attempts to explain and measure intelligence as a fixed or static, genetically-determined characteristic of an individual. Assessment technologies focused on the knowledge an individual had accumulated and could recall in response to the items on an intelligence test. Vygotsky (1978) was particularly frustrated by this orientation.

"Suppose I investigate two children upon entrance into school, both of whom are ten years old chronologically and eight years old in terms of mental development. Can I say that they are the same age mentally? Of course. What does this mean? It means that they can independently deal with tasks up to the degree of difficulty that has been standardized for the eight-year-old level. If I stop at this point, people would imagine that the subsequent course of mental development and of school learning for these children will be the same, because it depends on their intellect ... Now imagine that I do not

terminate my study at this point, but only begin it. These children seem to be capable of handling problems up to an eight-year-old's level, but not beyond that. Suppose that I show them various ways of dealing with the problem. Different experimenters might employ different modes of demonstration in different cases; some might run through an entire demonstration and ask the children to repeat it, others might initiate the solution and ask the child to finish it, or offer leading questions. In short, in some way or another I propose that the children solve the problem with my assistance. Under these circumstances it turns out that the first child can deal with problems up to a 12-year-old's level, the second up to a nine-year-old's. Now, are these children mentally the same?" (p. 85-86).

Most forms of dynamic assessment claim a connection to Vygotsky's work. Unfortunately, the Soviet political climate and Western psychometric orientation limited attention to his work until the 1970s. He proposed a construct, the zone of proximal development (ZPD; Vygotsky, 1978) to characterize the relationship between learning and development. A "ZPD is created by the interaction and is a function of the interaction" (Lidz, 1995, p. 148) in a teaching/learning context. It appears in the gap between the most difficult task a learner can complete independently (the actual level of development; ALD) and the most difficult task a learner can *learn* to perform independently with support (the level of proximal development). The broader the ZPD, the greater the learning potential.

The dynamism of learning in the ZPD is apparent in the nature of the social interaction between the learner and the tutor; learning is characterized by the child's 'progressive internalization' of the support offered by the tutor.

The process of internalization is gradual; first the adult or knowledgeable peer controls and guides the child's activity, but gradually the adult and the child come to share the problem-solving functions, with the child taking the initiative and the adult correcting and guiding when she falters. Finally, the adult cedes control to the child and functions primarily as a supportive and sympathetic audience (Brown & Ferrara, 1986, p. 281-282).

Throughout the intervening years, others insisted that any ecologically valid theory of individual differences in ability must reflect the fact that all learning occurs within the context of experience. Information-processing theories of intelligence began to distinguish more and less able individuals according to differences in their 'adaptive, goal-directed behavior' (e.g. Sternberg, 1985). Both of these pressures have brought us back to the orientations of the early 20th century with an emphasis on the role of adaptive interactions in context. Extensive descriptions of the history of efforts

assess learning ability can be found in Grigorenko & Sternberg (1998) and Guthke & Wingenfeld (1992).

### Research Employing Dynamic Assessment

#### Methods

Dynamic assessment (DA) researchers have selected tasks and designed protocols based on the goals, theoretical orientation, and practical demands of their work (Bransford, Delclos, Vye, Burns & Hasselbring, 1987; Hamers & Sijtsma, 1993). Many have modified the administration of tasks drawn from intelligence tests like the Ravens Standard Progressive Matrices and the WISC, and recent work has expanded this repertoire to include curriculum-based activities (e.g. Zorman, 1997). The nature of the support offered to students has ranged widely from providing standardized concrete hints (Kanevsky, 1990, 1992, 1994a, 1994b), examples (Stanley, Siegel, Cooper & Marshall, 1995), or graduated prompts (Brown & Ferrara, 1986), to unstandardized mediation (Feuerstein, Rand & Hoffman, 1979) involving "familiarization of materials, instruction of rules and problem solving strategies, and extensive feedback" (Hamers & Sijtsma, 1993, p. 369).

The next three sections describe studies employing a variety of DAs according to their purpose: identification processes using DA, improving test performance with mediation, and assessing ability-related differences in the zone of proximal development. This summary is limited to studies involving high ability students, however extensive summaries of the work involving other groups abound (e.g. Missiuna & Samuels, 1988; Campione, 1989; Haywood et al., 1990; Grigorenko & Sternberg, 1998). The DA work on giftedness is extremely young and diverse; as a result, this chapter will focus on methods rather than findings.

#### Identification Processes Using Dynamic Assessment

Both projects outlined here employ a multitude of instruments and procedures to locate the 'hidden talents' of students who are currently under-represented in programs for gifted students. In Project Synergy, Borland & Wright (1994) embedded a DA task in a comprehensive, three phase, identification process. Participants were from a low achieving, inner city school where the student population is 75% African-American and 25% Hispanic; and economically disadvantaged. Rather than investigating the validity of any one element of the procedure, they wholistically examined the validity of the entire year-long process.

The goal of Phase I was to develop a candidate pool of 35 to 40 from the Kindergarten classes totaling approximately 100 students. Classroom observations, multicultural curriculum-based enrichment activities, standardized assessment, portfolio assessment, and teacher nominations were considered. An academic

profile of each candidate was developed in Phase II; the DA task was administered along with a literature-based activity, standardized assessments of mathematics, reading and vocabulary, and an interview with the child.

For the DA task, Borland & Wright (1994) adapted matrix tasks like those in the Ravens Standard Progressive Matrices (RSPM; Raven, 1947) into a hands-on, interactive format for young children. One cell of each  $2 \times 2$  matrix was empty so the child was to identify the correct block to complete the pattern.

"Children who understand the task, apply an effective strategy, and solve many or most of the items correctly are allowed to complete the test without interruption. Children who do not solve most of the items correctly are questioned and given instruction to correct errors in strategy conception or execution. They then repeat the items missed. This continues until they experience success or it becomes clear that they are becoming frustrated and success is not forthcoming . . . We record the number of correct responses, the number of spontaneous corrections, the number correct following instruction, the child's strategy, and any other behavior displayed" (p. 167).

In Phase III, all of the information was considered and each case categorized as: (a) no special needs yet detected; (b) equivocal evidence, reassess in the future; or (c) clear signs of potential giftedness. Students in the first two categories were recommended for placements in regular classrooms with continued monitoring. Students in the third category were recommended for participation in a summer transition program intended to prepare them for placement in a school for gifted students. Five students (5% of the original Kindergarten intake) were ultimately admitted to the special school.

Preliminary efforts to examine the validity of this process were undertaken with follow-up testing during Grades 1 and 2; the results are promising. The students moved from the bottom quarter to the top third of the population on standardized tests of reading and maths by the end of first grade. By the end of Grade 2, their Stanford-Binet scores had gone from the 1991 range of 68 to 109 to a range of 104 to 139; a second cohort was identified in 1991-2 and efforts to track all of these students are currently underway.

The Project Synergy identification process has many strengths including its multi-dimensionality and rich information base for educational planning. Its disadvantages include the time and expense of broad-based testing and analyzing the information collected for each case study; still, Project Synergy demonstrates these costs may be worth the investment.

The Eureka Project is a long-term approach to identification through enrichment. Data are collected before, during, and after classroom intervention; this

test-teach-test design is consistent with the principles of DA. Other long-term procedures have been developed, however they lack baseline measures, distinguishing them as more performance-based than dynamic (e.g. Baldwin, 1994; Kay & Subotnik, 1994).

Eureka's two-phase process has spread from two schools in Tel-Aviv to 56 schools across Israel, serving students from a range of socio-economic and cultural backgrounds. The first phase (Exposure) involved DA in the visual arts and sciences, professional evaluation of portfolios (end of Grade 2) and task performance (end of Grade 2). The DAs of art and science potential employed a teacher rating tool for "specific aptitudes, interests and persistence in these talent areas" (p. 55). At the beginning of Grade 1 and the end of Grade 2, teachers used this instrument to evaluate the products and processes of students' work. It was the assess-learn-assess design that was considered dynamic, not the rating process. Once these data were collected at the end of Grade 2, each student's profile was examined for strengths and weaknesses. If a student was high in two of the three indicators in science or art, the student was encouraged to pursue special opportunities to develop that talent area in Phase II: Immersion. Non-identified students continued to participate in Exposure activities and assessments continued in order to find 'late bloomers'. In Immersion, the types of enrichment opportunities available varied depending upon school resources and students' needs.

Zorman (1997) provides preliminary and encouraging evidence of the reliability and validities (content, concurrent, and predictive) of the science and artistic potential instruments based on the performance of 34 science and 26 art students identified in the first two Tel Aviv schools. The project has also had positive effects on the overall school environment (e.g. art exhibits, science and art learning centers) and on the curriculum.

"Some of the teachers began to utilize items for the science and artistic potential instruments for observing students' behavior in their classroom in various subjects. For instance, some teachers observe and record students' process of developing hypotheses in the language arts, while other teachers observe student's motivation to cope with tasks and employ them in history and geography" (p. 60).

Both Project Synergy (described in Borland & Wright in this volume) and Eureka involve staff development to support the use of the new methods, raise teachers' sensitivity to indicators of latent potential, and encourage efforts to differentiate curriculum. These projects have operationalized the five elements in the identification paradigm proposed by Frasier & Passow (1994): new constructs of giftedness, absolute attributes and specific behaviors, cultural and con-

textual variability, more varied and authentic assessment and identification through learning opportunities. The preliminary indications of their validity, as well as these results, suggests a bright future for the contributions DA tasks, tools, and procedures may make to identification processes. In order to implement these approaches, schools will need to relinquish the common practice of one-shot assessment for a commitment to identification as a continuous process.

#### *Improving Test Performance with Mediation*

This group of studies focuses on change in unassisted test scores before and after instruction. The extent of the change was interpreted as the index of learning potential.

The first study to involve high IQ children was part of a series implementing three versions of the Learning Potential Tests (variants of the RSPM) to distinguish 'educationally retarded' children from developmentally delayed children who were more or less trainable (Badad & Budoff, 1974). All tests were administered in group settings; students were taught a pattern recognition strategy in the second session. Surprisingly, the 'subnormal' (mean IQ = 68) and 'average' (mean IQ = 85) groups made larger gains than the bright group (mean IQ 113); although the authors discounted the possibility of a ceiling effect, this possibility lingers.

Stanley et al. (1995) administered unmediated and mediated versions of the Peabody Picture Vocabulary Test (PPVT) to 39 students (19 gifted program participants from grades 2 to 9 and 20 regular Grade 4 students) to investigate the feasibility of their use in the identification of gifted students in rural settings. The PPVT assesses receptive vocabulary by asking the child to select one of four pictures that best illustrates each word's meaning. Two weeks after completing the PPVT without mediation, students were offered mediation with the words beyond their first session's top performance. This time the examiner repeated the word and used it in a sentence before the child selected a picture. No feedback or other instructional support was provided, making this the least instructive intervention of those offered in any of these studies; it could be argued that the limited nature of the mediation and the lack of a post-test mitigates its claims to being a DA study.

Not surprisingly, group means rose with the examples provided in the mediation; the gains reflected the same trends and concerns that were evident in Badad and Budoff's findings, i.e. the non-gifted group made greater gains. A ceiling effect was undeniable in this case as eight gifted and six non-gifted students achieved ceiling scores. The lack of a control group that had not received mediation on the second administration leaves potential practice effects unaddressed. The authors also used unmediated performance norms for the purposes of determining giftedness, e.g. "With mediation, 55% score as gifted" (p. 87); this is an

untenable practice as the mediation invalidates the norms (Embretson, 1987).

The next group of investigations employ tasks from the most comprehensive and fully developed DA measures (Grigorenko & Sternberg, 1998), the Learning Potential Assessment Device (LPAD; Feuerstein, Rand, Haywood, Hoffman & Jensen, 1986). The LPAD operationalizes Feuerstein's theory of cognitive modifiability in a set of instruments and procedures designed to "(a) to assess potential rather than manifest ability, and (b) to decrease the gap between functioning and potential" (Skuy et al., 1988). They involve static pretests and post-tests with mediated learning experiences between the testing sessions; the mediation, or instructional support, has cognitive and metacognitive elements.

The major difference between Feuerstein's work and other DAs is that the instruction is not standardized in any way; students are offered direct, personalized instruction in principles and strategies involved in task performance. This feature and minimal evidence of validity have attracted the most criticism (see Frisby & Braden, 1992; Büchel & Scharnhorst, 1993). Guidelines for the individually administered version are much more extensive than those for group administration (Rand & Kaniel, 1987). In both formats, eliciting a learner's 'peak performance' is the goal of the assessment process.

Feuerstein, Rand, Jensen, Kaniel & Turiel (1987) state, "the only group of individuals who are not viewed as legitimate targets for DA are those, who by virtue of their high and efficient levels of functioning, do not require modification" (p. 43). Therefore the LPAD and its variants (see for example, Wallace & Adams, 1988) have been recommended and applied in efforts to locate potentially gifted students in groups from disadvantaged, low SES contexts (e.g. Rand & Kaniel, 1987; Skuy et al., 1988; Hickson & Skuy, 1990; Sibaya, Hlongwane & Makunga, 1996). Only the group version of LPAD has been used thus far in efforts to locate gifted students, and consequently, only quantitative performance scores have been analyzed. Without the qualitative analysis of examiner-learner interactions from individual administrations, this work cannot extend the validity of Feuerstein's theory of structural cognitive modifiability to include high functioning students.

The three tasks implemented in these studies were selected from the LPAD battery because they involve "abstract thinking and representational behavior" and "possess a relatively high degree of complexity." They are the Organizer, Set Variations (I & II) and the Verbal Analogies Test. Like the tasks in the two preceding studies, they are based on items common on static intelligence tests; the items in Set Variations I & II are elaborations of the items on the RSPM (see Fig. 1). The student chooses the correct answer from eight alternatives; the mediation involves problem-definition,

focusing, rules for matrix problems, and sequencing. The Organizer asks the student to determine the possible location of objects based on incomplete information (Tzuriel, 1992; see Fig. 2); students need to analyze relationships, plan, and test hypotheses. This instrument is considered to have "a higher ceiling than other subtests" (Skuy et al., 1988, p. 96). In the Verbal Analogies Test (VAT), the examinee chooses one of six alternatives to complete standard verbal analogies ( $A:B = C:?$ ).

LPAD studies have focused on the relationships between gain scores and traditional measures of cognitive ability, school performance, and temperament. Skuy has been the lead author on all three LPAD studies with high ability students from low SES and immigrant backgrounds and the LPAD. The first and largest (total  $N=1041$ ; 165 superior students; 867 classmates) was undertaken in Israel with 9–11 year-olds (Skuy et al., 1988).

Intact classes of students completed the RSPM, the MILTA (Ortar, 1966; an Israeli test of intellectual ability), and the three LPAD instruments.

"In this study, mediation was applied to the planning, learning and execution of particular strategies required for dealing with the tasks/tests presented. The 'tester-as-mediator' adopted a teaching stance and promoted a learning set in her students. She attempted to communicate to the students the value and significance of the tasks, and led a discussion on the principles underlying the task, and an exploration of their application beyond the immediate situation, to a broader range of tasks and situations. In addition, by being given encouragement and specific and realistically positive feedback regarding their performance, the subjects' sense of competence was addressed and fostered" (Skuy et al., 1988, p. 92).

Comparisons of pre- and post-LPAD scores indicate superior students made relatively greater average gains only on the Organizer, not the RSPM. Group means did not change on the VAT. Thus it appears that only the mediation for the Organizer was more effective for the superior students.

Two South African studies reported by Skuy and his colleagues (Skuy, Gaydon, Hoffenberg & Fridjhon, 1990a; Skuy, Hoffenberg, Visser & Fridjhon, 1990b) included a control group (no mediation). In Skuy, et al. (1990a), numerous measures of school performance, cognitive ability (traditional and LPAD), and temperament were assessed as potential predictors of the criterion, performance in the Soweto Gifted Child Program (SGCP), a weekly five-hour enrichment program for superior students. In the second study, they limited their investigation to the relationship of LPAD gain scores and cognitive ability to teacher-rated temperament scores (Skuy et al., 1990b). Both reports drew on the same sample of more than 90, 13 to 18

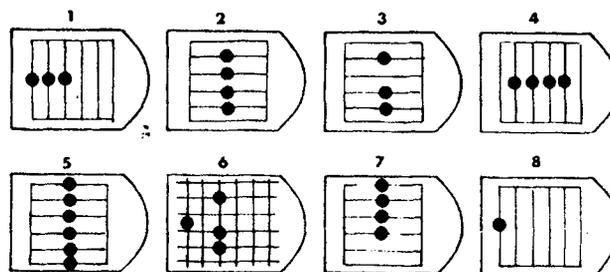

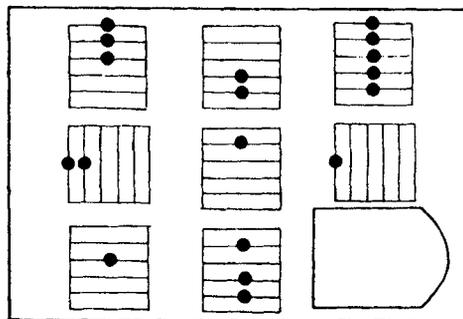

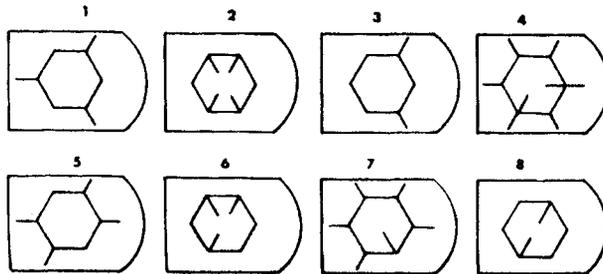

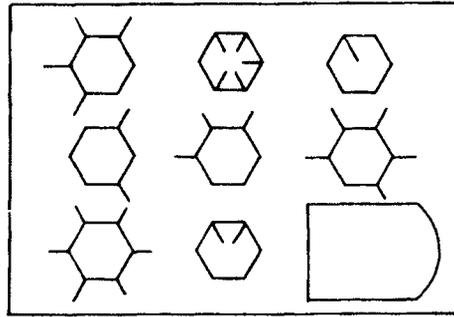

Figure 1. Example of Set Variations item from the LPAD. (Reprinted with permission)

Place the five children in their appropriate places.

- A. In the three places to the left are Don, Mike, and Tammy (not necessarily in that order).
- B. Mike and Allan are in the two outside places.
- C. John is on the right of Don.

Figure 2. Sample item from The Organizer (Skuy, Kaniel & Tzuriel, 1988).

year-old black students from ‘impoverished black ghettos’ participating in the SGCP.

The four variables accounting for 50% of the variance in SGCP performance were the VAT learning task (31%), school performance (a further 10%), the Organizer post-test (6%), and the Similarities post-test (3%). All of these measures, even for a group considered to be disadvantaged, reflect the type of verbal skills which consistently contribute to the academic success of superior students.

It is interesting that no mediated/non-mediated group differences were found on the LPAD tasks. The authors suggest this may have been due to the inexperience of the mediators, however this finding raises other questions as well. Considering the lack of ability-related differences on the VAT reported in the first study, the specter of ceiling effects looms, as do questions about the appropriateness of the mediation. It may be that mediation based on a deficit-oriented theory of cognitive modifiability needs to be revised to promote the growth of high functioning disadvantaged students.

The results of the study of temperament (Skuy et al., 1990b) indicated students judged to be high on Task Orientation (persistence) were higher academic achievers and high scorers on the LPAD learning tasks and post-tests. Those higher on Personal-Social Flexibility (more flexible and adaptable) performed better on the Organizer and Set Variations I and II, and the Ravens post-test. There were no group differences for Reactivity (frustration tolerance). These findings suggest personality variables need to be considered as factors affecting students’ learning potential.

Overall, the LPAD studies indicate the group administration of the Organizer has potential to screen ‘disadvantaged’ students for enriched learning opportunities. Perhaps one-to-one administrations in the future will enlighten efforts to revise the mediation offered in group administrations to enhance effectiveness when screening for potential giftedness. This work will also bring work with gifted students in line with

the original intent of the LPAD; it “seeks to determine the type and intensity of interventions that have to be offered to the examinee to produce a realization of that potential for change that may become revealed with the LPAD” (Jensen & Feuerstein, 1987, p. 395).

The consistent appearance of ceiling effects in all of these studies is evidence that even the ‘experts’ underestimate the learning potential of bright children when designing their research. Future research must attend to this and should give serious consideration to the controversies surrounding the use of gain scores (see Cronbach & Furby, 1970; Embretson, 1987; and Glutting & McDermott, 1990).

*Assessing Ability-Related Differences in the Zone of Proximal Development*

Like the LPAD, the post-tests in the next group of studies require demonstrations of transfer. Students continue to receive assistance if needed. The focus here is on the amount and nature of the assistance students need to achieve mastery (independent performance on the learning and transfer tasks). This distinguishes it from the work in the preceding sections, which has focused on the amount of improvement achieved from pretest to post-test (Brown & Ferrara, 1986). In addition, the samples in these studies were from ‘majority’, middle class, English-speaking backgrounds. Although the majority of Brown and her colleagues’ work has involved low functioning and disadvantaged students, only the work with high IQ children will be included here.

The theoretical orientation of Brown, Campione and their colleagues is explicitly Vygotskian and was stimulated by Brown’s first visit to the Institute of Defectology (Moscow) in 1978 (Brown & Ferrara, 1985). Brown and her colleagues interpret the ability to use learning from the first task to reduce the need for assistance (number of hints) on transfer tasks as an index of the breadth of the ZPD. In a study involving children having a broad range of normal and high IQs (88–150), Ferrara, Brown & Campione (1986) reported

evidence of the concurrent and predictive validity of graduated prompting procedures. In a graduated prompting procedure, the tutor provides the learner with a series of standardized supports. Examples of the tasks and hint procedures described below are from the Letter Series Completion task used in the validation study:

Original learning task: N G O H P I Q J \_ \_ \_ \_  
Far Transfer task: U C T D S E R F \_ \_ \_ \_

“... hints proceed from quite general or abstract hints to extremely explicit and concrete ones. The two initial prompts were general ones that redefined the task. The next five were more specific and pointed to the periodicity and relations among the letters. The following four hints were more concrete in that they involved colorful transparencies that made the relations and periodicity even more salient ... The last four hints gave the answer to the child one letter at a time” (Ferrara, Brown & Campione, 1986, p. 1090–1091).

Concurrent validity was established by the significant relationship found among the amount of assistance needed (number of hints), IQ, and age. The amount of assistance required decreased with increasing IQ and age. These relationships were not perfect, indicating that although intelligence and this measure of learning potential were related, the measures are not redundant. Predictive validity was evident in the significant relationship between gain scores and IQ.

In other studies using standardized prompts, Brown and her colleagues found consistent IQ related differences in children’s transfer propensity (potential to generalize their learning) (e.g. Campione, Brown, Ferrara, Jones & Steinberg, 1985). This relationship increases with greater transfer distance, i.e. children with higher IQs needed less assistance as the extent of differences between the learning and transfer tasks increased. Based on theirs and related work, they concluded that bright children have broader zones of proximal development, i.e. they learn more quickly and transfer more broadly. They explain that this is

“... because they know more about learning in general and *supply for themselves* the information that is not afforded. They apportion effort appropriately, continually monitor progress, know when and how to seek advice, and so on ... More capable students also prepare for transfer and engage in sophisticated reasoning aimed at accessing and using current knowledge. They prepare for transfer, for example, by regarding ‘new’ problems, not as isolated ones, but as instances of a general class (e.g. Scribner & Cole, 1973); they expect that what they learn may be relevant elsewhere and entertain hypotheses about where and when. Simply knowing that transfer is desirable from prior situations to the current one, or from the current one to future ones, is

itself part of the battle. Good learners perform thought experiments, seek appropriate analogies, and understand some of the principles involved in learning and reasoning from incomplete knowledge” (Campione & Brown, 1984, p. 286).

Kanevsky extended this work and its theoretical implications. She maintained the test-train-test-near transfer-far transfer procedure, yet differences were evident in the sampling strategy, the task, the hints and the addition of a qualitative analysis of the children’s behavior. Her analyses explored differences in young (ages 4–8) children’s problem solving related to chronological age, mental age, and IQ using an extremely high IQ comparison group (Kanevsky, 1990, 1992, 1994a). The mean IQs for the average ability students was 104 and 153 for the high. The high IQ preschoolers had been matched for mental age with the average ability Grade 2s.

Two versions of the Tower of Hanoi puzzle (hands-on and computer-based; see Fig. 3) were used because, according to Piaget (1976), young children would not be able to complete them independently. The goal of the ‘game’ was to move the three layers from one outside peg to the other outside peg, one layer at a time, in seven moves. The hints offered were concrete (direct instruction consisting of the best next move toward the goal) compared to Brown & Ferrara’s (1986) more strategic support.

Like Brown & Ferrara (1986), analyses of the total number of hints used indicated that the high IQ children had broader ZPDs, as they learned more quickly and generalized their learning to a greater extent (Kanevsky, 1990). The high IQ and older children were also found to be more accurate in the moves they made, they were more independent, understood their mistakes better, and learned from them. ‘Floor’ and ceiling effects were apparent. The ‘floor’ was too high for 11 average IQ pre-schoolers who found the computer-based puzzle too difficult. A ceiling effect arose among the high IQ Grade 2s. Their erratic performance and comments indicated the task was too easy (Kanevsky, 1994). Neitze & Rohr-Sendle-meier (1992) also found that levels of performance and effort deteriorated when gifted adolescents were given an unchallenging, but age appropriate version of the Catell Culture Fair Test.

Kanevsky’s (1992) qualitative analysis documented ability-related differences in the interplay of children’s goals, motivation, and metacognition. Some of the high-IQ children were intrinsically motivated to enhance their fun by monitoring and maintaining their own challenge level. They spontaneously elaborated on the basic task or connected the game with personal experiences. The average-IQ children appeared more extrinsically motivated by the researcher’s interest in their success. Scruggs (1986) also observed this pursuit of complexity in his examination of the learning

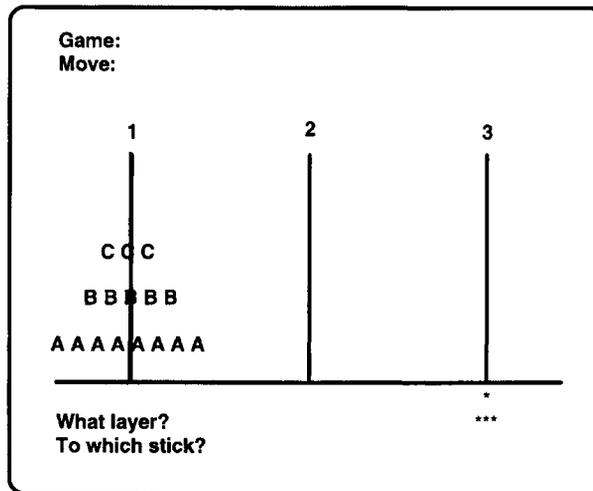

Figure 3. Screen display for the computer-based Tower of Hanoi (Kanevsky, 1990).

strategies employed by average and high ability seventh- and eighth-grade students. He reported: "The results were remarkable. These gifted students had transformed what appeared to be a rote learning task into a problem solving activity, in which the problem was: 'How can I learn these nonsense words most effectively?'" (p. 294).

Further evidence of their concern for efficiency was apparent when the high-IQ children spontaneously decided to pursue a quick, independent solution in the least number of moves (Kanevsky, 1992). A meta-cognitive interpretation of this group difference would be that while the OA child was asking herself, "What is any move I can make?" the high IQ child would be asking, "What is the *best* next move I can make?"

Ferrara et al. (1986) and Kanevsky (1994c) both found significant, but far from perfect correlations between IQ and hint totals, indicating static measures of general intellectual ability are related to the breadth of the ZPD, but are not perfect predictors. Thus, the ZPD and IQ provide related, but different views of learning. Additionally, the ZPD appears to be domain specific (Tissinck, Hamers & van Luit, 1993; Day et al., 1997) while most intelligence tests target more general cognitive abilities.

### Issues, Trends and Recommendations

#### *Psychometric Concerns*

The desire for levels of standardization and objectivity expected of psychological tests (Hamers & Sijtsma, 1993; Anastasi & Urbina, 1997) are vigorously challenged by those, like Feuerstein, who argue for flexibility. Certain individually administered domain- or task-specific DAs using standardized prompts (e.g. Brown) have come closer to achieving these goals than

group versions that rely on flexible interaction procedures (e.g. the group LPAD).

DA techniques have evolved to a point where researchers and advocates of each approach can no longer ignore calls for evidence of their reliability and validity (Embretson, 1992; Grigorenko & Sternberg, 1998). In clinical applications, it may be more appropriate to seek 'credibility' (as in qualitative research) rather than traditional forms of validity. Embretson (1987) and Sijtsma (1993a, 1993b) suggest DA research should move away from Classical Test Theory to Item Response Theory and latent trait modelling, because these techniques will more accurately test and reflect the complexity of interactive learning environments and the multidimensional nature of learning.

It seems every feature of DA has been criticized by psychometricians and often with good reason (e.g. Cronbach & Furby, 1970; Embretson, 1987, 1992; Sijtsma, 1993b; Guthke, Beckmann & Dobat, 1997; Grigorenko & Sternberg, 1998). Practitioners and researchers interested in measuring potential giftedness using this methodology would be wise to consult these sources to avoid the pitfalls of the research and development efforts that have preceded them.

#### *Methodological concerns*

*Samples.* Passow & Frasier (1996) pointed out, "A paradigm or model for identifying talent potential should have applicability to all students, not just the economically disadvantaged or the advantaged" (p. 200). All of the DA techniques here need to be tested with a broader spectrum of students. Eureka-style programs and the LPAD need to be applied to samples of 'advantaged' children, as well as ZPD studies of high functioning disadvantaged students.

*Differential effects of interventions/mediation.* Comparisons of the various interventions (e.g. Brown's graduated prompts vs. Feuerstein's mediated learning) with non-gifted students indicate that they differ in their effectiveness (Bransford et al., 1987; Jitendra & Kameenui, 1993). These studies should be extended to include gifted students so as to investigate potential interactions between the nature of the assistance (i.e. abstractness and complexity, feedback, metacognitive content, verbalization) and non-intellective variables (i.e. personality, creativity) (e.g. Carlson & Wiedl, 1992).

*Task difficulty.* To avoid the ceiling effects found in many of these studies, future research must raise or, if possible, remove the ceiling on task difficulty so the full breadth of the ZPD can be activated and explored.

*Scoring and coding.* Limiting analyses to pre-post changes in test scores ignores the potential of DAs to provide rich data regarding interactions among many variables: changes in the nature of children's knowledge and skill, their goals, interest, motivation, personality, etc. Reliable and valid coding systems can be developed to track these changes as well as those in the tutor/learner interaction. Clinicians and researchers are encouraged to consult Smagorinsky's (1995) discussion of the methodological challenges in assessing the ZPD, include subjectivity and purity of data, and identifying an appropriate unit of analysis.

*Ecological validity* is the extent to which the ability being assessed is authentically contextualized in 'actual working conditions' (Gardner, 1992). One approach to establishing the ecological validity of DA for school-based learning potential has been to assess learning potential and the differential influences of classroom instructional strategies (e.g. Campione & Brown, 1987; Palinscar et al., 1991; Kanevsky, 1994c; Jitendra & Kameenui, 1996).

*Individual and group assessments.* The test format must be appropriate to the purpose to be served by the results. In individual assessments, "A diagnostician has to concentrate on assessment using some qualitative criteria of the developmental stages of different functions, their interactive relationships, and individual profiles of processing capabilities" (Gajdamaschko, 1999, p. 90). This information can contribute to educational planning in ways that group test scores and gain scores cannot. In contrast, group dynamic testing can be useful in preliminary screening for enrichment (Rand & Kaniel, 1987).

#### *Theoretical concerns*

Vygotsky was "concerned about the development of processes that generalize across domains, processes

also referred to as meta-cognitive or executive, that express unique human characteristics of self-consciousness and permit self-regulation" (Lidz, 1995, p. 149). This concern for the shift from other- to self-regulation has not always been evident in the goals of instruction/mediation, data collected or its analysis. For example, gain scores may reflect change but show no concern for the interactions so essential to learning in the ZPD (Minick, 1987; Lidz, 1995) or the nature of the changes in learning or understanding.

Feuerstein has a theoretical and methodological commitment to overcoming cognitive deficits resulting from a lack of appropriate mediation. He has stated, "Children at a low functioning level in school can benefit most from mediated learning experience" (p. 206). It was never his intention to apply his theory of the LPAD with advantaged, high functioning, successful students. Inconsistent results found with the LPAD tasks raise doubts regarding the feasibility of extending his work beyond disadvantaged students. This suggests that DAs driven by Vygotsky's work, or other more inclusive, developmental theories may be more appropriate for work with gifted students.

#### *Practical concerns*

First and foremost, advocates must remember that DA is a methodology, not a complete identification procedure; it can act as one dimension of multi-dimensional identification procedure, as it does in Project Synergy and Eureka.

DAs have some practical obstacles to overcome. Individually administered tasks (pretest/baseline, teaching/learning, and posttest/transfer) are costly in terms of the time required to train examiners as well as the time required for administration and interpretation (Stanley, 1993; Borland & Wright, 1994). The range of tasks and materials available is limited and those that are available may have ceilings so low that they are ineffective with high functioning students. Developing a reliable, valid, standardized series of tasks, prompts, scoring and interpretation procedures is a monumental challenge.

On the other hand, the time, effort, and money may be the key to ensuring that the potentials of all students are fairly assessed. DAs can be designed to provide static and dynamic results, thereby reducing the need for separate static tests of domain knowledge. This is unlikely to happen, however, unless the demand increases for finding students with potential to become gifted in the future, in addition to those who are already outstanding.

Informal DA and instruction can be designed by teachers for particular skills, such as vocabulary building, summarizing (Paris & Jacombs, 1987), solving mathematical problems (Jitendra & Kameenui, 1996), and to suit the needs of particular communities. Bolig & Day (1993) suggest teachers can use it to "determine what a child has already learned (i.e. pretest

performance), how easily the child learns (i.e. the number of hints needed, the number of explanations required, or the amount learned from an instructional session), and how readily the child transfers newly acquired knowledge or skills following complete instruction” (p. 112).

In addition to these benefits, Tzuriel (1992) points out that DAs can reduce the ‘communication gap’ that often exists between educators and psychologists when discussing the results of a student’s assessment.

“Instead of talking with teachers about remote concepts that mainly concern psychologists (e.g. discrepancy between verbal and performance scales, the psychological meaning of figure drawings), I can talk about learning processes, behavior problems that might affect learning, mediational styles, strategies for effective change, and the educational philosophy that I believe should be adopted in dealing with learning problems” (p. 320).

## Conclusion

Learning is complex and so is the problem of assessing it well; DA has only begun to contribute to understanding, identifying, and responding to extraordinary learning potential. Future research should pay closer attention to the basic methodological and psychometric lessons learned by earlier researchers with non-gifted samples. We also need to take advantage of more sophisticated technology and statistical procedures when appropriate, and to analyze the rich process data available in DAs; this is happening outside of the gifted literature. One example of the DA research benefiting from the power of computer technology is apparent in the work of Guthke, Beckman & Dohat (1997). They have developed a computer-administered, individualized, standardized, adaptive battery of learning tests. In terms of the potential for improved statistical techniques, one can refer to the work of Embretson (1987). Among others, she has recommended and applied Item Response Theory and latent trait analyses to examine the data derived from her research implementing DA methods.

The flexibility of the test – learn – test paradigm offers teachers, psychologists, and researchers enormous opportunities to address their shared concerns for fair assessment, a better understanding of the learning process, and its role in talent development. With this tool, we can strengthen the theoretical and practical foundations of gifted education.

# Early Identification of High Ability

Christoph Perleth<sup>1</sup>, Tanja Schatz<sup>2</sup> and Franz J. Mönks<sup>3</sup>

## Introduction

### *Approaches to Identifying Early Indicators of Giftedness*

One of the first complex study designed to determine indicators of intellectual giftedness was carried out by Terman (1925) and his colleagues. The longitudinal investigation beginning in 1920 included 1528 school children having an IQ of 135 or above. Although one may criticize the Terman study for its lack of a control group, the selection procedure and other reasons (e.g. Rost, 1993), the researchers did determine—retrospectively—several differences between their more gifted and less gifted children. The more gifted children were able to walk about one month earlier and their language development began about 3.5 months earlier than the less gifted children. In addition, approximately 50% of the children studied could read before entering school. Parental interviews suggest that these children can be characterized by rapid comprehension, insatiable curiosity, familiarity with things, excellent memories, large vocabularies and an unusual interest in numerical relationships (Terman & Oden, 1947).

Following in the footsteps of Terman, giftedness researchers attempted to identify indicators which predict excellent performance in school or even in later life. In considering the promise of development, researchers have primarily worked on the following areas: sleep, habituation, memory, concentration or attention, information processing and accelerated development in individual areas, etc. Most of the research was done in a retrospective way, i.e. questionnaires with possible indicators were given to the parents of gifted children and youth asking about interesting aspects of the (early) development. On the basis of these, behavioral checklists (e.g. Stapf & Stapf, 1994) were then constructed for early identification of gifted or promising children.

When faced with the problem of identifying and fostering infant or early development of high ability

today, it is apparent that the traditional approach of identification has become increasingly questionable. Tannenbaum (1992), for example, compared different studies of child prodigies. He demonstrated that the hope placed in such children by researchers, teachers and/or parents was frequently misplaced.

This contribution will primarily emphasize a developmental or prospective perspective. It will to a considerably lower extent take a retrospective approach about the developmental relevancy of personality and environmental factors of infant prodigies as expertise researchers do (Perleth, 1997). Crook & Eliot (1980) showed that predictions of this sort are often faulty. A more fruitful approach is to prospectively examine indicators which can be used to predict the developmental course of gifted individuals.

When considering early identification of children with intellectual gifts and talents, one question should always be asked: Is it necessary to identify such children before school age, or as some research (e.g. habituation and sleep studies) indicates as early as infancy? Obviously, during the preschool years, the primary goal should be the guarantee of optimal child development. Decisions about the fostering of giftedness should be based on adequate diagnostic information about the status and prediction of personality development.

## Models of High Ability

In this chapter, our understanding of high ability or giftedness are those capacities and competencies found in the infant and child which are relevant for learning processes. We, therefore, do not subsume constructs such as musical or psychomotor giftedness under the term high ability, but view this, as Campione, Brown & Ferrara (1982) expressed, as: “the ability to perform well in school-like and test-like situations” (p. 392). In the following, we will therefore only deal with a segment of that which makes up modern conceptions of giftedness (e.g. Gardner, 1983, 1995; Tannenbaum, 1986; Perleth & Heller, 1994; Perleth, 1997, 2000).

### *Traditional Psychometric Approaches*

Traditional approaches to intelligence and giftedness continue to play the most important role in the research

<sup>1</sup> University of Rostock, Germany.

E-mail: christoph.perleth@philfak.uni-rostock.de

<sup>2</sup> University of Rostock, Germany.

E-mail: Tanja.schatz@philfak.uni-rostock.de

<sup>3</sup> University of Rostock, Germany.

E-mail: monks@psych.kun.nl

about and fostering of gifted children. These include psychometric measures, especially intelligence tests, which are the most often employed instruments for identifying gifted children in research and everyday practice. The most widespread tests are, with very few exceptions, e.g. the German Rasch-scaled test for 'Adaptive Intelligence Diagnosis' by Kubinger and Wurst (2000), based on formulas of classical test theory (e.g. Lord & Novick, 1974).

### *Information Processing Approaches*

In the framework of psychometric intelligence theories, primarily the relationship of various dimensions of intelligence as well as the concurrent and predictive validity of the tests is important. On the other hand, information processing or cognitive approaches aim at identifying and analyzing the components and processes which interact when cognitive tasks are solved (Waldmann & Weinert, 1990).

Frequently cited and reliable cognitive or information processing models of intelligence are those of Sternberg (e.g. 1985, 1993) and Campione & Brown (1978; see also Borkowski & Peck, 1986). Whereas Sternberg's model certainly initiated fruitful research in the area of giftedness, the Campione and Brown model seems useful for classifying some often cited early indicators of giftedness, despite the fact that this model was originally derived from research with retarded children.

In the Campione & Brown model (1978; see also Borkowski & Peck, 1986) the 'architectural' level, i.e. the 'hardware' of the cognitive apparatus, comprise a three-storage space memory model (sensory register, short-term memory STM, long-term memory LTM; for summary see Wessells, 1984). The characteristics of these entities, i.e. their capacity (number of entities that can be stored in the STM or LTM), duration, and efficiency, do not underlay developmental processes. Therefore, they are neither changeable nor trainable.

The speed of information processing and retrieval represents the operative efficiency of the system. While capacity and duration are—according to the authors—not related to intelligence, the efficiency is regarded by Campione et al. (1982) as a determinant of intelligent behavior. Other authors (e.g. Jensen, 1969; Neubauer & Knorr, 1998) put this speed of information processing in the center of their theoretical conceptions of intelligence. These and similar conceptions of intelligence refer directly to the unchangeable hardware properties of the cognitive apparatus.

The higher 'executive' system in Campione & Brown (1978) is made up of the following components: (a) The knowledge base in which the whole world knowledge of the child is organized and represented, whereby the knowledge can be regarded both as a symptom and as a determinant of extraordinary achievement. Further components represent (b) rules and strategies, and (c) metacognition/metamemory

(knowledge about strategies, knowledge about the task, knowledge about characteristics of one's own cognitive apparatus) and executive metacognitive control processes. The latter are used as metacognitive components in the regulation in memory tasks (see also Borkowski & Peck, 1986), processes of comprehension, or in problem solving. These components of the executive level which are considered, for example, to strongly influence memory performance, underlay 'dramatic development' processes (Campione & Brown, 1978, p. 284), and can also be improved by training measures.

### *Achievement Oriented Approaches*

A third approach for investigating gifted children is represented by the expert-novice approach (Ericsson, 1996; Ackerman, 1992; see also Schneider, 1993, or Perleth, 1997, who summarize theories and research of acquisition of expertise). In this research paradigm, the special abilities or skills of young experts, prodigies, or precocious children are investigated. Fields of interest for research on the gifted are early reading/writing, mathematics, music and arts, and so on (see e.g. Burns, Collins & Paulsell, 1991; Lamb & Feldhusen, 1992; Winner & Martino, 1993; Davidson & Scripp, 1994; Baum, Owen & Oreck, 1996; Robinson, Abbott, Berninger & Busse, 1996; Snowden & Conway, 1996; Stainthorp & Hughes, 1998).

Methodologically, research using this approach compares young experts in a specific domain with average children who do not possess the skills under investigation, or to a lesser extent. One research question is to analyze what precocious children do when solving tasks, so that aspects of the cognitive component and the cognitive correlates approach are touched upon. The other question is whether intellectually precocious children will maintain their advantage in later school years so that these extraordinary skills can be used as early indicators of high ability (see Perleth, 2000). Because of the limited space of this chapter, however, we have to refer to other chapters in this volume which cover areas of infant and child expertise or precocity.

### **Identifying Young Gifted Using Psychometric Methods**

Psychometric instruments for the assessment of high ability or rather intelligence are broadly used in research and practical attempts at identifying and nurturing gifted children. Nevertheless the psychometric approach in identifying the young gifted is crucial: We know from research with 'normal' samples that we cannot assume either high reliability of intelligence tests nor stability of measured traits in preschool children (see Sattler, 1988, for a comprehensive review). The following short descriptions of different tests focus on test properties which are most important for identification of gifted children: above all

reliability, norms, and predictive validity. Especially with regard to the latter, we have to face the fact that nearly no longitudinal studies have been conducted which followed preschool and early elementary school children for a minimum of several years to analyze possible indicators and determinants of giftedness and achievement. The volume by Subotnik and Arnold (1994) on newer longitudinal studies of giftedness, for example, lists only three projects which investigated the development of giftedness in young children (younger than 8 or 9 years); one of these is limited to the musical domain, a second to the evaluation of a gifted program, and only the third one covered a broad area of giftedness factors and achievement areas (Perleth & Heller, 1994; see also Perleth, 1997, 2000).

### *Tests of 'General' Intelligence*

Although newer conceptions of giftedness or intelligence more frequently make use of multidimensional models, the tests generally used in the identification of gifted children represent measures of general intelligence subsuming verbal, mathematical, figural, memory, and other tasks in one or few global scores. While such a procedure can be criticized when applied to youth and adolescents, it can be considered less problematic in young children because factor analytic research seems to show that the structure of intelligence become more differentiated with increasing age. Therefore, multidimensional tests such as the Cognitive Abilities Test series (Thorndike & Hagen, 1987) propose global intelligence scores for young children. In the following we provide an overview of the intelligence tests most frequently used with young gifted children including information available on their reliability and predictive validity in this population. See Sattler (1988) for a comprehensive critical overview of intelligence tests available in English-speaking countries.

### *Stanford-Binet Intelligence Scale*

The Stanford-Binet Intelligence Scale: Fourth Edition (SB:FE) by Thorndike et al. (1986) is the current version of the Stanford-Binet intelligence test originally developed by Terman on the basis of Binet and Simon's scale. The SB:FE is the successor of the 1960 Stanford-Binet: Form L-M (SB:L-M) for which new norms were published in 1973 by Thorndike. These 1973 norms were used for much of the research reported in this chapter. According to the very informative manual by Thorndike et al. (1986), the new SB:FE provides the examiner with an overall score for general intelligence which is composed of three dimensions measuring crystallized abilities, fluid abilities, and short-term memory. The crystallized abilities contain two scales for verbal and quantitative reasoning, while fluid abilities are made up of items of

abstract/visual reasoning. The test can be used with children from the age of 2 years.

Since Terman (1925) used the Stanford-Binet (SB) in his classical giftedness study, the SB is still very popular in the field of giftedness-research and practice, although the modern version has not too much in common with the SB Terman used. Many authors stress that the SB differentiates better in the extremely high range of intelligence. This additional advantage could be concluded from the fact that the norm tables provide values up to IQ 170 (e.g. Freeman, 1979). In our view, this is too optimistic for the following reasons. First, the standard deviation (s) of the SB is 16 so that in comparison with the 'normal' IQ-scale (mean:  $M = 100$ ,  $s = 15$ ) the SB provides slightly higher values. A SB-IQ of 130, for example, is equivalent to an IQ of 128 measured by a Wechsler test. Second, the standardization samples of both the SB:L-M and the SB:FE are much too small to calculate IQ scores above 130 (see below).

To judge the predictive validity of the SB for gifted children, the classical study by Terman & Oden (1959) is often cited. These authors discovered a good concordance between childhood and adult IQ scores. Interpreting this, however, you must take into account that Terman (1925) did not begin his study solely with young children but with 4–14 year olds (median between 9 and 10). Kangas & Bradway (1971) report for the preschoolers of the 1937 standardization sample of the SB correlations of  $r = 0.59$  and  $r = 0.41$  with SB-scores measured 25 ( $N = 109$ ) and 38 years ( $N = 48$ ) later.

Perleth, Lehwald & Browder (1993) report a number of studies in normal samples which showed that the prognostic validity of the SB between early childhood or preschool age at the one side and primary school age at the other is quite low (not higher than about  $r = 0.35$ ). For samples of gifted children Robinson (1987) reported a retest correlation of  $r = 0.75$  for preschoolers assessed at age 2 and 6 ( $N = 16$ ),  $r = 0.59$  between children of age 3 and 6 ( $N = 117$ ),  $r = 0.61$  between age 4 and 6 ( $N = 74$ ), and  $r = 0.71$  between age 5 and 6 ( $N = 25$ ). Although Robinson (1987) judges these results as 'relatively low' (p. 162), they show in our opinion that intelligence as measured by the SB is a relatively stable trait even in the preschool age. Laurent, Swerdlik & Ryburn (1992) also give a positive judgement about the usefulness of the SB:F-E for diagnostic in gifted children.

Shapiro, Palmer, Antell, Bilker, Ross & Capute (1989) tried to predict WISC-R IQs measured at age 7.5 (a sample of 200 children containing 36 gifted) with developmental indicators assessed at 7–12 months and SB:L-M scores evaluated at 3 years. While the correlation between the SB-scores and the WISC-R were medium at least for the WISC-R full-scale, it was not possible to predict giftedness at age of 7.5 with the SB in a discriminant analysis. The results were not

better for the other indicators in the study. The authors conclude that “the expectation for precocious infants to become precocious children, while appealing, is not supportable” (Shapiro et al., 1989, p. 209).

Sometimes short-form versions of the SB are used (e.g. McCallum & Karnes, 1990, for the SB:F-E). In some studies these forms turned out to perhaps be appropriate for screening purposes (see Perleth et al., 1993; McCallum & Karnes, 1990, found—on average—slightly higher results with the full form). In any case we would completely agree with Robinson (1992) who argues that the SB:L-M should not be used any longer in the identification of gifted children.

### Wechsler Intelligence Scale

The Wechsler Preschool and Primary Scale of Intelligence—Revised (WPPSI-R) (Wechsler, 1989; the WPPSI was published in 1967) and the Wechsler Intelligence Scale for Children—Third Edition (WISC-III) (Wechsler, 1991) which succeeded the WISC-R (Wechsler, 1974) are the second most widely used intelligence tests in gifted children. The tests measure ‘the aggregate or global capacity of the individual to act purposefully, to think rationally and to deal effectively with his environment’ (Wechsler, 1958, p. 7). In consequence, the most frequently used indicators derived from the tests are the total score and the global scores for the verbal and performance scale. Although there have been some studies of the factor structure of the test (see Sattler, 1988, for a comprehensive overview; also Brown, Hwang, Baron & Yakimowski, 1991; Wilkinson, 1993; Masten, Morse & Wenglar, 1995), alternative scores or the profile are seldomly used for scientific or practical purposes. As in the Stanford-Binet, the Wechsler scales have been shown to be sufficiently reliable and valid for the assessment of general intelligence in gifted children (Kaufman, 1992; Kaplan, 1992; Bracken & McCallum, 1993; Spangler & Sabatino, 1995; Sparrow & Gurland, 1998).

A major problem in using the Wechsler test for studying gifted young children occurs when longitudinal research is planned. The WPPSI-R covers an age range from about 3 to 7 years while the WISC-III is constructed for 6 to 16;6 year-olds. As the WPPSI-R does not contain all subtests of the WISC-III and the two tests overlap only for the 12 month period between 6 and 7 years, it is problematic to switch between the two tests. Sattler (1988) questions the general interchangeability of both scales (referring to the WISC-R of course, the argument, however, can be extended to the WISC-III).

From their factor analytical findings, Schneider & Gervais (1991) conclude that the verbal and non-verbal part of the WPPSI-R should be considered separately (see also Wilkinson, 1993). According to Mark, Beal & Dumont (1998) a short form of the WISC-III can be used as a screening method for identifying gifted

children. Linville, Rust & Kim (1999) showed that even a single subscale of the WISC-III (picture completion) could be applied as such a screening tool.

### Tests of Specific Abilities

#### Kaufman Assessment Battery for Children

The Kaufman Assessment Battery for Children (K-ABC) (Kaufman & Kaufman, 1983) can be used with children from 2;6 to 12;6. The four scales available give information on the sequential and simultaneous information processing, the child’s factual knowledge and skills (so-called Achievement Scale), and non-verbal reasoning abilities (score composed of subtests from the sequential and simultaneous processing scales). The K-ABC was normed with 200 to 300 children for each age group. The reliability of the test is as sufficient as those for the SB or WPPSI/WISC-R, the validity with regard to the underlying information processing model of intelligence seems unclear (see Sattler, 1988, for a critical review of the test).

Swanson, Brandenburg-Ayres & Wallace (1989) investigated the construct validity of the K-ABC in children from gifted classes (N=169). They found a factor structure of the test which differs from the one reported for normal children in the manual. In the sample of Swanson et al. (1989) a hierarchical model was established by exploratory factor analysis. The model subsumed a verbal memory, non-verbal memory and non-verbal reasoning factor under a (weak) factor of general intelligence. Therefore, the usual K-ABC factor structure supporting the model of simultaneous and sequential processing was not confirmed for gifted children. From the methodological point of view, however, it has to be stated that the intercorrelations between the K-ABC subtests were very low (<0.25). Analyzing the K-ABC subtests, Cameron, Ittenbach, McGrew, Harrison, Taylor, Hwang (1997) found support for Cattell’s or Horn’s distinction between fluid and crystallized ability.

With respect to the fairness of the K-ABC, Nolan, Watlington & Willson (1989) could not find indications of a systematic bias in the K-ABC items against gender and race in gifted and non-gifted children (using the standardization sample of the test). This confirms the results of McCallum, Karnes & Edwards (1984) who found hints that the K-ABC is more suited for the identification of minority children than the WISC-R or the SB. Meanwhile, however, a verification of the norms with respect to gifted children seems to be necessary.

### Tests of Nonverbal Reasoning Abilities

The Progressive Matrices (Raven, Court & Raven, 1983, 1986) measure non-verbal reasoning abilities (inductive reasoning) without verbal, quantitative, or memory aspects. Therefore they are sometimes classified as tests for general intelligence in the sense of Spearman (Heller & Perleth, 2000). The Colored and

Standard Progressive Matrices are available for the purpose of assessing intelligence in gifted young children. They cover an age range from 5 to 11 and 6 to 17 years, respectively. The fact that there are no verbal items makes the tests attractive for the assessment of children from minority groups or risk groups (e.g. foreign children, children from underprivileged families and so on).

#### Peabody Picture Vocabulary Test

The Peabody Picture Vocabulary Test—Revised (Dunn & Dunn, 1981) or the British Picture Vocabulary Test (Dunn, Dunn, Wetton & Burley, 1997) is—in spite of its exclusively verbal character—sometimes used as a screening test for the selection of gifted children (see Hayes & Martin, 1986). Norms are available from 3 to 16 years. Sattler (1988) judges the reliability and validity as sufficient, warns, however, against the use of the PPVT-R as a “screening device for measuring intellectual level of functioning” (p. 350). Bracken, Prasse & McCallum (1984) give an overview of research available on the PPVT-R. The use of the test as a (screening) instrument for identifying gifted children, however, can be criticized from methodological point of view (e.g. Hayes & Martin, 1986; Tarnowski & Kelly, 1987) as well as because of the exclusively verbal character of the test.

#### Developmental Tests

As the intelligence scales described above are not available for very young infants, developmental scales such as the Bayley Scales of Infant Development (BSID-II, Bayley, 1993; original version published 1969) are sometimes used for the estimation of the cognitive level of gifted children. The Bayley Scales, from which an index for mental development can be derived, for example, can be applied from 1 months to 3½ years of age. In this age, however, the course of development is inter- and intraindividually very unstable, and thus the use of these scales is questionable for the detection of early signs of giftedness.

Results of the prospective studies using developmental tests indicated, all in all, that developmental indicators of early infancy are not appropriate for prognosis of later intelligence or ability in gifted children (Perleth et al., 1993). The overview by McCall (1979) for normal children shows that higher correlations could be obtained with children older than 18 months because in the first month the developmental tests assess sensorimotor more than cognitive functioning (Sattler, 1988; Shapiro et al., 1989).

#### Comparison of Different Measures and Problems Related to the Psychometric Approach

Nearly all studies in gifted young children employ tests of cognitive functioning. The results of these tests are, on the one hand used as indicator of intelligence, high abilities, or giftedness itself. On the other hand, if an

alternative definition of giftedness is used, intelligence or abilities tests are used as reference variables, e.g. to make the samples of different studies comparable. There are several problems to be regarded if the psychometric approach is used in giftedness research.

As mentioned above, many practitioners and researchers look for tests which provide them with differentiated norms in the upper extreme. Concerning the SB, the SB L-M is therefore sometimes preferred to the newer SB:FE because of better discrimination in gifted children (Kitano & DeLeon, 1988; Silverman & Kearney, 1992). A similar argument was, for example, expressed against the K-ABC by Roberson (1988, cited by Storfer, 1990). In our opinion, this seems to be an unrealistic expectation. The 1973 standardization of the SB was done on the basis of about 2,100 testees, the one of the SB:FE on the basis of about 5,000. This means that, on the average, the norms for each age group were computed on the basis of only 100 or 300 persons. In samples of that size, you find on the average 2 or 6 persons with an IQ higher than 2 standard deviations (s) from the mean (M), and you probably find no person with an IQ higher than  $M + 3s$  (i.e.  $SB-IQ > 148$ ). To be sure that a sample contains 10 gifted persons with an IQ over  $M + 2s$  ( $SB-IQ > 132$ ) you have to collect a representative sample of  $N = 438$ . In order to find a single person with an IQ higher than  $M + 3s$  ( $SB-IQ > 148$ ), respectively  $M + 4s$  ( $SB-IQ > 164$ ) on the basis of the deviation IQ you need a sample of 741 and 31,546 persons respectively. These examples show that it is not at all realistic to gain valid IQ-scores that are able to finely differentiate between persons with an IQ higher than  $M + 2s$  ( $SB-IQ > 132$ , Wechsler-IQ  $> 130$ ). Thus, norm tables that provide you with such extreme values are constructed on the basis of random extrapolation and smoothing but not on the basis of empirical data of representative samples.

As a consequence, profile analysis with gifted children is in most cases very difficult or even impossible as these children may score beyond the ceiling of the subtests. Reynolds & Clark (1986) propose a procedure with the help of which the subtest scores can be restandardized intraindividually using the norms of older children or those from higher grades and thus making profile analysis possible. Prerequisite for this is that age or grade norms of the test are available and the reliabilities and the structure of the subtests across age or grade are the same.

There is a great deal of evidence that there has been a shift in the mean IQs of children and adults (Flynn, 1987; see also Storfer, 1990). There also was a shift in the IQs from the SB L-M of about 10 points from the 1960 to the 1973 norms (see e.g. Roedell et al., 1989). As can be read in the SB:FE manual (Thorndike et al., 1986), a sample of gifted individuals which was administered the SB L-M and the SB:FE scored 13.5 points higher on the 1973 SB L-M than on the 1986

SB:FE (similar results are reported by Robinson, Dale & Landesman, 1990; Kluever & Green, 1990; McCall et al., 1989). With respect to the other tests, the SB:FE manual contains information that children classified as gifted by their schools reached a mean composite IQ of 123.2. In comparison with the WISC-R full scale score, the SB composite score turned out to be slightly lower (1.4 points), while children scored even lower in the K-ABC composite score than in the SB:FE (4.7 points). As can be seen from Thorndike et al. (1986), the differences are smaller for samples of individuals with average ability.

Findings on mean differences between tests was confirmed for gifted by McCallum et al. (1984) who report that gifted children score lower on the K-ABC than on the WISC-R or the SB L-M. With respect to the PPVT, Knoff & Blednick (1986) found a difference of more than 10 points between the older PPVT and the newer PPVT-R, while in a study by Bondy et al. (1984) gifted children scored 8–20 IQ points higher in the Slosson test than in the McCarthy test.

Results of such studies are of major importance for giftedness practice and research as severe consequences for recruited samples of gifted children are related to the question of which test and which norms were used. If the IQ shift between the SB L-M and the SB:FE is 13 points in the upper extreme, a gifted sample gathered using  $IQ > 132$  using the old SB L-M in 1985 does not contain the top 2% of the population but the best 10%.

Apart from the problem of the test norms, comparing samples recruited by different measures of intelligence requires 'comparable' instruments. The question of concurrent construct validity, however, is difficult to solve for gifted children. For average, heterogeneous samples, Thorndike et al. (1986) report high correlations between the SB:FE and the WISC-R ( $r=0.83$ ), the WPPSI ( $r=0.80$ ), as well as the K-ABC ( $r=0.89$ ) which is even higher than the correlation between the SB:FE and the SB L-M which is  $r=0.81$ . Such correlations are necessarily lower with gifted samples because of the reduced variance in such samples (Perleth & Sierwald, 2000). McCallum et al. (1984), for example, report a correlation of  $r=0.5$  between the WISC-R and the K-ABC for gifted samples. For a sample of 82 gifted primary school students, Thorndike et al. (1986) found a correlation of only  $r=0.26$  between the SB L-M and the SB:FE which has to be explained by reduced variances and invalid IQ scores in the extreme upper range of the SB L-M. Comparing tests for identifying gifted children should also include a comparison which children are identified as gifted by the respective tests and which not. The results of Beal (1995) show that for example the WISC-III and the Otis-Lennon assign children to similar giftedness groups.

Modern approaches in constructing measures of cognitive functioning—apart from the further develop-

ment of traditional, well-accepted tests—can be described by at least three important trends. First, the results of the information processing approaches should be used in a stronger way to establish measures for components of intelligence. The K-ABC may be given as a first attempt for of this, other examples of genuine information processing character, however, have still to be developed (see Pyryt, 1996).

The second trend refers to the placing of training and transfer in the center of theories of intelligence. Using a pretest-treatment-posttest design, Guthke (1974, 1992) began in the sixties to develop so-called learning tests which assess the 'learning potential' of the child in the sense of Vygotsky's theory of zone of proximal development. Later, a similar test-teach-test approach was developed independently in the Anglo-American countries under labels such as dynamic assessment or learning potential assessment device (Feuerstein, 1980; see also Campione et al., 1982; Bolig & Day, 1993; Borland & Wright, 1994; Kirschenbaum, 1998). The ideas common to both the German and the American tradition is the assessment of the level a child can achieve given ideal teaching or the advancements that can be obtained through training. But up till the present time, no real usable tests of this kind are available (see Pyryt, 1996).

A third trend is the development of adaptive or tailored tests. If tests of this kind are given to children, the children work only on these items that are best suited to measuring their ability. This means that gifted children only complete rather difficult items. This normally necessitates computer-aided testing. With the help of probabilistic test theory, ability parameters for each child are available and comparable, even if completely different subsets of items are administered to every child (e.g. Embretson, 1985; Embretson & Hershberger, 1999). For German-speaking countries, Kubinger & Wurst (2000; see also Kubinger, 1998) presented a paper-pencil-test for adaptive intelligence diagnosis. Following a concept similar to the WISC-R, this AID II enables the measurement of intelligence in gifted primary school children with good precision.

With regard to the question of the extent to which later (superior) performance can be predicted on the basis of tests administered during preschool and early school years, we have to state that no precise answer can be given based on the presently available (or rather lack of) empirical evidence. There are far too few prospective studies or at least combined longitudinal-cross sectional studies which could provide practitioners and researchers with respective data.

In general, the abilities measured by intelligence tests are quite unstable in preschoolers. While Sattler (1988) found a correlation of  $r=0.5$  from 7 to 8 years of age with youth and adult intelligence and achievements, the same author states: "The older the child is when first tested and the shorter the interval is between tests, the greater the constancy of the IQ" (p. 73). Thus,

IQ scores measured prior to 5 years of age must be interpreted cautiously. Fluctuations of as much as 20 IQ points are possible, even if the oscillation of the IQ for the majority of children is lower after age 5 (Sattler, 1988; Cahan & Gejman, 1993, report quite stable IQ-scores for primary school children; similar Perleth & Sierwald, 2000). The same holds true for the relationship between intelligence and achievement (which can be moderated, for example, by external factors).

In view of this state of the art, further evaluation of relatively well-known tests in samples of gifted children are preferable to the construction of new instruments for identifying young gifted children. On the other hand it should be stated that the situation is totally different for older students. Perleth (1997, 2000) for example found for the German CAT high stabilities of intelligence scores over 2 years in samples of over average and gifted students. The intelligence measures also showed satisfactory prognostic validity with school completion grades over up to 8 years.

Nevertheless, practitioners and researchers should be sceptical of too much optimism about the possibility of predicting high ability and high achievement from early age. According to Howe's (1990; see also Ericsson, 1996) critical summary prognoses must be made with extreme caution. This holds even more true as most of the research was done with older children or youth. Also considering the results from the Terman study, Howe (1990) concludes that "such tests are especially ineffective at making predictions that concern the achievements of individuals who are highly able" (p. 202).

### Information Processing of the Young Gifted

The subsequent section follows the outlined information processing model of intelligence presented above. Since parameters of information processing in newborn and infants are measured primarily in habituation studies, we have included a subsection on this. We have also included a section on sleeping behavior under the topic architectural level as this is frequently reported as an important early indicator of giftedness, especially in German-speaking countries. Possible links of sleep parameters to giftedness have to be on this 'hardware' level. With concern to the higher order components, we summarize knowledge base and strategies as declarative and procedural knowledge on the one hand and strategy use, metacognition, and executive control on the other hand.

#### *Architectural Level*

##### Attention and Habituation

As infant intelligent tests have little predictive validity, researchers have turned to other areas promising better results. Indeed it would seem that cognitive functioning makes great developmental leaps during the first two years of life. In habituation studies, a (generally visual)

stimulus is repeatedly presented until the subject ceases to attend to it. Typically, infants placed in otherwise homogenous environments will orient and attend to a novel stimulus. This attention will diminish if the stimulus is presented continuously or repeatedly. Bornstein (1988, 1989) explains habituation using a two-component process: The infant develops a mental image of the stimulus and continually compares the mental image to the stimulus presented. A representational match will not hold the baby's attention, but mismatches maintain it. Abroms (1982) reported that high newborn cry counts, rapidity of visual habituation, and other parameters of early attention and information processing might precede advanced cognitive development.

From our point of view, it is important that habituation studies have linked intelligence or cognitive functioning to early habituation results. Lewis & Brooks-Gunn (1981) view habituation to redundant information and recovery when stimulus is changed as perceptual-cognitive ability or information processing. These are abilities who can be examined even in very young infants. The developmental theory upon which their research is based assumes that different skills develop at different ages and 'those central to a specific age group are most likely to be predictive of the next major skill, even though the next skill might be quite different from the preceding one' (Lewis & Brooks-Gunn, 1981, p. 132).

To put it briefly, cognitive ability is a transformation of skills from one age level to another. The research of Lewis & Brooks-Gunn (1981) did, in fact, provide a better prediction of intellectual functioning at 24 months (Bayley scores) from 3-month habituation/recovery than 3-month (Bayley scales) global intelligence or object permanence scores. Their research results are also supported by Bornstein & Sigman (1986), who showed that attention focussing at six months may be used as a predictor of subject's IQs between two and eight years of age, and Rose & Wallace (1985), Fagan & McGrath (1981), and Fagan and Singer (1983) also discovered a relationship between preference for novel stimuli and mental abilities. Bornstein & Sigman (1986) explain the early habituation and the later intelligence as both reflecting effectiveness in encoding information. Thus, more intelligent infants encode everything of interest or perhaps they more quickly match it to their mental representation. Lécuyer (1989), however, judges these correlations as less substantial and argues that—amongst other methodological problems—the '0.05 syndrome' (p. 149) might have suppressed the publication of lower correlations or studies in which no relationships between habituation and later cognitive indicators were found.

Of course, as Tannenbaum (1992), points out, neither habituation nor response to novelty actually requires reasoning or logic, but rather are viewed as

being measures of efficiency in information processing. That is, they are a means of predicting later intellectual functioning without explaining the relationship between habituation and IQ. But all in all the amount data is rather small with respect to young gifted children.

#### Memory Capacity and Durability

Although it has often been shown that gifted children's memory performance is better than that of average children (Abroms, 1982), these results are generally not interpreted as meaning higher memory capacity or memory durability in gifted children. Memory capacity here means the number of 'slots' of the working and long-term memory rather than measures of the memory span where the number of recalled words or numbers can be increased, for example, by using appropriate strategies. On the contrary, there is much evidence that there are hardly differences in the capacity and durability of the short-term or working memory as well as the long-term memory of children and adults of different level of giftedness and of different ages (Howe, 1990).

All differences in memory performance reported in the literature have to be attributed to differences in speed of information processing (memory or cognitive efficiency) or in higher order components as knowledge, metamemory, and executive control which lead to a more efficient use of the limited capacities of the short-term memory (see e.g. the surveys of Campione et al., 1982; Jackson & Butterfield, 1986; Borkowski & Peck, 1986; Brewer, 1987; Torgesen, Kistner & Morgan, 1987). In addition, Schneider & Pressley (1997) argue that intraindividual development changes in memory performance cannot be linked either to changes in capacity or to speed of information processing.

#### Memory Efficiency

Although Schneider & Pressley (1997) deny a causal relationship between intraindividual development of memory performance and speed of information processing, the efficiency of the memory system is considered to be the main cause on the architectural level of interindividual differences in the achievement of gifted, average, and retarded children (see literature cited in the last paragraph). Memory or cognitive efficiency refers primarily to the speed of information processing. This includes properties of the sensory system and the short-term memory and, in consequence, the speed of registering, identifying, and analyzing incoming information, the speed of storing new information in long-term memory as well as the speed of retrieving information from memory, the speed with which information in the working memory is processed etc. All in all, cognitive efficiency enables one to make better use of the limited capacities of the

working memory. Memory efficiency increases as cognitive processes become more and more automatic: Automation frees capacity of the working memory and at the same time attention for more complex problems. Thus, the superiority of gifted children may be attributed to higher cognitive efficiency, i.e. to a higher basic speed of information processing and a higher level of automation.

While aspects of attention, memory, and cognitive efficiency are regularly included in checklists for the early identification of gifted children, there is not much empirical evidence for the concurrent and predictive validity of these indicators in young children. In our opinion this is a consequence of the methods employed. Information processing in infants up to one year is measured using the habituation paradigm (see above; for a methodological discussion see Daehler & Greco, 1985) while recognition tasks, reaction time tasks and so on have normally been applied in children older than nine or ten years. Thus, there are few studies with children under eight or nine years of age investigating cognitive efficiency in gifted children. On the other hand, there are many more studies dealing with retarded or learning disabled children. Possible relations between cognitive efficiency and later achievements were demonstrated, for example, by Jackson & Myers (1982) who could show for 37- to 66-month-old preschoolers that rapid letter naming and backward digit span was a predictor of reading skills six months later while no relationship could be found between measures of IQ (e.g. Stanford-Binet, WPPSI-subscores).

There is some evidence that memory efficiency concerning retrieval processes cannot be associated uniquely with differences in the basic speed of information processing (Brewer, 1987). The superiority of the gifted in cognitive efficiency may be also caused by enhanced attention processes, a superior organization of the knowledge base, more effective strategies, a better motivational structure, longer and more intensive practice, or the complex interaction of all these and other components.

#### Sleep

Occasionally, descriptions of young gifted children include the idea that the gifted child sleeps less than other children and/or has sleep problems (see Freeman, 1979; also Louis & Lewis, 1992). Frequently, behavioral checklists, especially ones for the hand of parents and teachers, include an item such as the following from Geuss & Urban (1982): Needs comparatively little sleep and this irregularly (p. 94, checklist for early identification of giftedness). This continues to be reported by parents, practitioners, and is reflected to a certain extent in the literature. As a consequence of this reduced need of sleep and irregular sleeping times of gifted newborns and infants—according to respective literature—the parents of the gifted may be under

considerable strain (e.g. Webb, Meckstroth & Tolan, 1985; Stapf & Stapf, 1988; Heinbokel, 1996).

The empirical evidence for these indicators is rather poor. Despart (1949, cited along with Busby & Pivik, 1983), for example, reported shorter sleep periods of the gifted but did not present any statistical or polygraphical evidence for this statement. On the contrary, Terman (1925) stated that his sample of gifted children (age 7 to 14) slept even longer than normal children. In accordance with this result, Freeman (1979) reports that in her study no differences were found concerning sleep behavior and sleep problems between gifted controls and non-gifted control children. Only the parents of the children of the so-called 'target group' which consisted of gifted children whose parents were members of the English National Association for Gifted Children reported a lower amount of sleep and more sleeping problems for their children. In a similar way, the sample of Stapf & Stapf (1988), who also report a low sleep need for young gifted children, was collected in a counseling center. Browder (1993), on the other hand, could not find a difference in the sleep length between gifted and average children, using reports of the parents who did not know that their children were gifted.

Freeman (1983) suggests that sleep problems tend to be more an indication of parental attitudes: The parents of the gifted children tend to be middle class, and at the same time expect their children to sleep more than working class parents. Thus they put their children to bed earlier. "Quantity of sleep depends on what parents expect and on the children's psychological adjustment" (Freeman, 1983, p. 30) and, therefore, in her opinion sleep cannot be regarded to be an indicator of giftedness.

This view is confirmed by a look at the general sleeping behavior of infants and toddlers. As Wolke (1993) points out, the variance of sleeping behavior is intra- and interindividually, as well as interculturally, extremely high. Twenty to 38% of all parents, for example, consider night-waking a mild or serious problem for their families' life; about 6–10% of all toddlers wake more than twice per night.

A major problem in the research on the sleeping behavior of gifted infants is the retrospective way in which the indicators were collected. To our knowledge, there are no prospective studies investigating the relationship between sleeping behavior of newborn or young infants which turned out to be gifted in later childhood or in primary school. On the other hand, there are some longitudinal studies on representative samples or on children at risk which can provide some information about the correlation between sleep behavior and intelligence and other indicators of cognitive capacity in school time. Pollock (1992), for example, reports that the British Birth Survey (17,196 children) "has failed to show any association" (p. 165) between sleeping behavior at early infancy and intellectual

abilities at age ten, only a slight superiority of the children with sleeping problems in a vocabulary test at age of five and a reading test at age ten was found.

Researchers who compared not sleeping behavior but sleep patterns and sleep variables of mentally retarded and normal children were a little more successful. From such research it seems to be obvious that the REM latencies are longer, the REM sleep is shorter, and the eye movement density during REM sleep is less in the mentally retarded (Busby & Pivik, 1983; Grubar, 1985). Studying normal children alone, however, Borrow, Adam, Chapman, Idzekowski & Oswald (1980) could not find any association between these parameters and intellectual ability. In general, however, the reliability and validity of such research is critical as the recording of physiological functions is stressful and often unacceptable in infants and young children so that their ecological validity has to be questioned (Wolke, 1993). In consequence, sleep studies with gifted children under the age of eight years are, to our knowledge, not available.

All in all, the evidence from the sleep studies of Busby & Pivik (1983) and Grubar (1985) is small, contradictory and drawn from samples of older children. Considerably more efforts have to be undertaken to clarify the sleep characteristics of gifted infants or children. At the present state of research, sleep variables cannot be taken as early indicators of giftedness, even if Grubar (1985) hopes that the measurement of sleep variables may enable a new way of assessment of intellectual potential. In consequence, corresponding items in checklists reflect myths or more or less subjective impressions of the staff in counseling centers rather than empirical findings.

### *Higher Order Components*

#### *Knowledge Base and Strategies*

The knowledge base is frequently regarded as an important component of giftedness (e.g. Chi, 1984). Muir-Broaddus & Bjorklund (1990) see differences between gifted and average children not so much in the use of strategies or executive processes but in non-strategic aspects, above all the knowledge base (also Harnishfeger & Bjorklund, 1990). The authors report that their research results show that 'typicalness' evaluation of concepts with regard to their categories of more intelligent 10 to 14-year-old children are similar to those of adults. In comparison with average children, this adult-like knowledge base can be observed primarily in the reproduction time of words of different categories, while no differences between giftedness groups could be found concerning words of the same category. On the other hand, with regard to clustering behavior, Muir-Broaddus & Bjorklund (1990) found no significant differences between the groups, whereby a trend in favor of the average students had to be reported. Hasselhorn (1996) concludes on the basis of a series of well designed studies that during primary

school time there is a substantial change from non-strategic, knowledge base driven 'clustering' to intentional strategic behavior. This might indicate that cognitively advanced children use more strategies but respective studies are rare, last but not least because studies investigating strategies, knowledge and metacognition (see next section) in young children are very critical from the methodological point of view (Schneider & Sodian, 1988). Meanwhile Bjorklund and coworkers also reported a strategic superiority—at least partly—of gifted children (e.g. Gaultney, Bjorklund & Goldstein, 1996).

Bjorklund & Schneider (1996) gave an overview of the research investigating the connections between intellectual ability, knowledge base, strategic behavior and memory achievement. The authors stress that measures of intelligence include aspects of metacognition and processing speed, both of which also exert an influence on memory and learning. So a large, elaborated and well structured knowledge base can be considered as a core function of all (intellectual) achievements even if one does not follow the extreme position of Ericsson (1996; see above). Concerning aspects of the knowledge base in (young) gifted children, still too few studies are available. McFarland & Wiebe (1987) already stated that "there is a certain irony here: the complexity and methodological sophistication used to study mentally retarded children clearly surpasses that used to study cognitively superior children" (p. 109).

#### Strategy Use, Metacognition and Executive Control

In the tradition of Flavell & Wellman (Flavell, 1971; Flavell & Wellman, 1977; Flavell, 1978, 1984), we use the term metamemory or metacognition, on the one hand, to refer to the knowledge about the capacity/efficiency and about the function of one's memory or the whole cognitive set-up. Seen from an alternative theoretical point of view (e.g. Brown, 1978, 1984), metacognition means the cognitive processes which—referring to the respective demands—plan cognitive processes, which choose adequate cognitive strategies, which execute and control them in reference to their efficiency.

As demonstrated above, metacognitive knowledge and metacognitive control processes play an eminent role in newer theories of intelligence and giftedness (Campioni & Brown, 1978; Sternberg, 1985, 1991; Ferretti & Butterfield, 1992). Quite surprisingly, however, there are only a handful of studies on metamemory or metacognition in younger gifted children. Studies with gifted pupils have been carried out mainly with primary school children or adolescents older than 8 years (for a summary see Perleth et al., 1993). One of the reasons for this might be the fact that research in metacognition—especially if one focuses on knowledge aspects—calls for a certain reflection

ability which emerges only gradually during the course of childhood development. This would indicate that it should be even easier with gifted children whose language might be more elaborate.

Some research, however, has been conducted in young children investigating metacognitive control processes. Here the way children cope with a problem, whether they adopt a trial-and-error strategy or whether they switch to systematically checking and comparing different possibilities, or whether they reflect on the problem-solving processes are aspects of metacognitive control with direct relations to success in the respective task. Such control activities are acquired in interaction with parents or other persons while the child is brought up (Karnes, Shwedel & Steinberg, 1982; Kontos, 1983; Browder, 1993).

In order to increase our understanding of how the antecedents of metacognition are structured, we must deal closely with the caregiver-child interaction, in which metacognitive directions are provided as verbal or non-verbal aids. They help the child wake up to his/her own storage capacities. Gifted children eagerly seize on such metacognitive directions provided by a caretaker (information about task and strategy characteristics, and about the child's personality characteristics that interfere with the problem-solving process). Without subjecting them to much experimentation, gifted children use directives to expand their repertoires of verification procedures (Lehwald, 1992).

Moss (1990) and Moss & Strayer (1990) investigated the problem-solving behavior of three to four-year-old gifted and average nursery school children of a (upper) middle class area in Montreal. They examined their play with blocks when the problem was solved in the presence and with the help of the mothers. As a result, Moss & Strayer (1990) determined that the mothers of the gifted focussed the attention of their children on important relations between problem aspects while the mothers of the average gave more hints about concrete solutions. All in all, the mothers of the gifted provided their children with a more favorable environment for the formation of metacognitive competencies. The gifted children used metacognitive strategies after the modelling of their mothers, but also more and more spontaneously during the task (see also Browder, 1993).

With respect to primary school children Perleth (1994) conducted a series of studies to investigate differences in strategy use and metamemory (related to a sort-recall-task) between groups of different levels of giftedness and to analyze whether training and transfer effects depend on the level of giftedness. As main results Perleth (1994) had to state that the differences in strategy use between gifted and normal children were smaller than expected, especially less apparent among second-graders (about 8 years old) but relatively larger in more distant transfer tasks. Intelligence

correlated better with memory performance than did metamemory.

As a result of his compact survey, on a very general level one can state (e.g. Heller, 2000), that gifted can be distinguished from the average by their better information-processing competencies. They make use of relevant information for problem solving, they perform comparison processes more quickly, and spend, however, more time for the encoding phase (more careful problem analysis). Gifted use more and better strategies for problem solving in different areas, they substitute more favorable strategies for unsuitable ones more quickly, and their cognitive monitoring is better (for summary see Waldmann & Weinert, 1990; Robinson, 1993; Shore & Kanevsky, 1993; Sternberg, 1993).

Some authors, however, could not find superiority of gifted children in metacognitive variables in general. Swanson, Christie & Rubadeau (1993), for example, report good strategic behavior of gifted children or youth which, however, was independent of metamemory. Swanson (1992) attributes the superiority of gifted children to their superior central processing system. Carr, Alexander & Schwanenflugel (1996) summarize the research on metacognition in gifted children by conceding better declarative metacognitive knowledge and strategy transfer but they do not outperform average children in strategy use and monitoring abilities in general. The metacognitive superiority of gifted children is above all obvious in high achievement in specific domains. Coyle, Read, Gaultney & Bjorklund (1998) could show that cognitive stability and low variability in strategy use was the prominent characteristics of gifted children which lead to higher achievement in memory tasks.

Up till now there is a body of evidence worth mentioning which shows that gifted children profit from strategy use and metacognitive abilities especially in more complex and more demanding tasks. So efforts for improving especially strategy use and metamemory of gifted children (see Manning, Glasner & Smith, 1996, or Van Der Westhuizen & Rautenbach, 1997) seem to be promising.

### *Motivational Characteristics*

While motivational aspects are regarded as core presumption of excellence in general from all theoretical positions—see for example the controversy between Ericsson & Charness (1994) and Gardner (1995)—motivational aspects play a smaller role in investigations in preschool or young children (also Porath, 1996). More information is available for primary school and older children (e.g. Clinkenbeard, 1996). In his representative and methodologically well controlled study in primary school children, Rost (1993) found that gifted children can be positively distinguished from average controls with respect to

achievement motivation and causal attribution. Moreover, their strategies of working through their failure are more favorable. Concerning other aspects of personality, only a few differences were found, but when, then to the advantage of the gifted children.

As motivational characteristics develop to a great extent during primary school time, most studies in motivational variables concentrate on older children and youth. At the end of primary school gifted children show higher intrinsic motivation (Gottfried & Gottfried, 1996).

An important motivational aspect important for development of high ability can be seen in the curiosity and interest of even the young infant, i.e. the attention and preferences which are given to objects in the environment (Howe, 1990; Johnson & Beer, 1992). These motivational characteristics manifest themselves in a child's behavior. Because of their curiosity, gifted children already attract attention in early stages of development (Schneider, 1987). Berg & Sternberg (1985) view curiosity as an integral part of giftedness. In a meaningful and profound manner, the gifted children typically integrate the information acquired into their knowledge base. On the basis of their knowledge and a critical analysis of the consequences of their knowledge, they make decisions on courses of action geared to their original intention (acquisition of knowledge). Even at an early age, the behavior of gifted children is marked by a clear goal orientation. That orientation and its development is facilitated by these children's enhanced concentration power (Freeman, 1990).

During childhood, curiosity manifests itself in exploratory behavior. Therefore, the latter may be used as an early indicator of intellectual functioning. Exploratory acts are forms of active learning typical of young or preschool children. We are dealing with these when children expand and differentiate cognitive structures or when they incorporate these into a wider system (Keller, Gauda, Miranda & Schölmerich, 1985). In the course of mental development, the forms of exploratory behavior undergo change. These forms range from simple experimentation (mouthing, beating, shaking things) through functional/relational manipulations (assembling and integrating objects) to the asking of questions, a language-based information-seeking process. For differential diagnostic purposes, exploratory behavior may be used in a particularly impressive way, as a 'response to novelty'. In such situations gifted children focus their attention on relevant pieces of information. It may be that this has to do with the exceptional ability of gifted children to identify problems (Renzulli & Delisle, 1982).

Empirical work (Lehwald, 1990) has shown that gifted, curious children make impressive use of their exploratory skills in puzzles. They relate single objects to complex units significantly more frequently than do less curious children. Thus, in a largely unstructured

situation (at play, for example) they generate information themselves, and in doing so are engaged in an intensive information gathering process about the properties of objects, how objects are interrelated, what functions they have, and what functional relationships can be established. In the long run, such active learning is conducive to the development of cognitive abilities. Follow-up studies using an intelligence test showed curious children to be clearly superior to less curious children. Thus, the exploratory actions which gifted, curious children engage in are of high 'cognitive relevance'. If environmental conditions are fortunate, they perform a developmental function. If a child's social environment provides an abundance of information, exploratory actions will build up a rich knowledge base, which is characteristics of gifted children (Siegler & Kotovsky, 1986).

### **Social Environment of the Young Highly Able Child**

As Tannenbaum (1992) pointed out, many children showing signs of giftedness in toddlerhood or in the preschool age, do not achieve an outstanding level at school or later achievement in life. According to Lewis & Michalson (1985), one explanation for this discrepancy between promise and fulfillment can be the family background and educational-career opportunities. Families select and produce opportunities and experiences for the development of their children, and thus play an essential part in the growing of giftedness. Consequently, the development of giftedness is a function of individual characteristics, environmental experiences, and the interaction between both factors (also Bloom, 1985; Perleth, 1997, 2000)—apart from the role of mentors and models for the development of gifted children (Pleiss & Feldhusen, 1995).

Analyzing the socio-economic background of the families of gifted children and adults, a number of typical factors were identified. The majority of the students identified and traced by the classical Terman study turned out to stem from a wealthy and intellectual milieu. These findings of above-average education and socio-economically well placed families of the gifted was replicated regularly in giftedness studies (see Lewis & Michalson, 1985; Bix, 1988, for mathematically talented).

Howe (1990) points out that among extremely successful scientists (e.g. winners of the Nobel prize) religion, size of the home city, etc. distinguish them from the population in general. Considering these findings that so many identified gifted children come from the middle and upper socio-economic classes, Roedell et al. (1989) address the problem of identification of gifted from other social and educational classes, a topic on which more research was done during the last decade (Ford & Harris, 1990; Rhodes, 1992; Scott, Deuel, Stoyko & Urbano, 1996; Passow & Frasier,

1996; Tomlinson, Callahan & Lelli, 1997).

According to Howe (1990), individuals who later became scientists in particular come from intact families, enjoyed their childhood, and their career was straight and not interrupted by (family caused) critical life events. The parents of the gifted children from Berger's (1984) sample reported that their children were planned, and that pregnancy and birth were free from worries and problems. Most children had attended kindergarten.

The more sociological family characteristics described, however, cannot explain why they favor the development of highly able children. To obtain more insight into the shaping of giftedness, factors such as educational style, family climate, or attitude about learning and schooling have to be analyzed. According to Lewis & Michalson (1985), for example, an optimal amount and balance of freedom and pressure most favorably influences a child's motivation to learn and to explore the environment. Sometimes, however, gifted stem from families where parents stress discipline from the early childhood on (Berger, 1984). Gruber, Weber & Ziegler (1996) report that many members of A-class orchestras as the Munich symphonic orchestra were forced to exercise during their youth crisis by their parents.

Beginning with a representative sample totaling more than 7000 eight-year-old pupils recruited all over Germany (all of whom were tested individually), Rost (1993) compared 151 gifted elementary school children with 137 average control children which were matched by social class, age, school, grade, and sex. In contrary to other findings comparable family structures and family relationships were found in both the gifted and the control group. Moreover, the fathers and mothers of both groups had the same educational goals, and no differences were found with respect to patterns of parental behavior and parental beliefs.

Based on an example of Jewish families descending from Europe, Howe (1990) describes mechanisms of how giftedness can be fostered by the family environment and background factors such as educational aims, attitude towards achievement, religion, and so on (see also Storfer, 1990). The Jewish families are mostly intact and stable, with two parents at home. Their living circumstances in urban or suburban environments provide good cultural opportunities. As demanded by the Talmud, the fathers are the first to teach their children and this takes place at an early age. The parents encourage activities that lead to success at school, while little emphasis is placed on sports. The whole lifestyle is one where scholastic activities are enjoyed and respected, the families witness the successful outcomes of sustained efforts to learn new skills. Most interestingly, studying is allowed on Sabbath but other activities are forbidden.

Roedell et al. (1989) draw the conclusion from research on the family environment of the gifted that

parents should spend a great deal of time with their children, read frequently to them, answer their children's questions in a proper way, support their children's own reading attempts and interests, and all in all, demonstrate a positive basic attitude towards intellectual learning. According to Howe (1990), however, girls are often confronted with traditional role models and encounter severe opposition to careers from their families. Encouraging and helping every child to acquire knowledge and skills should be focus of parental educational efforts. On the other hand, Howe (1990) warns that some parents are too anxious and too ambitious about the development of their children (see also Perleth & Sierwald, 2000). In any case, families of gifted children have to be seen as to be at risk (Robinson, 1998)

### Practical and Research Desiderata

Early identification of young gifted children necessitates methods which are able to discover those children who promise high achievement in later school or professional careers. With respect to psychometric tests and as well to other early indicators of giftedness described in this chapter or in (behavioral) checklists, this necessitates first of all high reliability, fairness, and high predictive validity. To prove that a test has sufficient reliability for purposes of identifying promising children, it is not enough to determine its parallel test or consistency reliability. Instead one has to show that the retest reliability is high since the assumption is that the measured trait or indicator is stable over the course of time.

For identifying young gifted children, proving prognostic validity of the test and the giftedness indicators used plays a central role. This seems to be a main problem as the predictive power of a method can only be demonstrated in longitudinal studies. In the case of identifying gifted children, such studies would require very large samples and the tracing of the sample over many years. Moreover, all tests and questionnaires should be completed under the supervision of trained researchers, as for example Rost (1993) did in his study. To check the prognostic validity of an instrument, it is namely not enough to watch a sample of gifted and checking whether they indeed achieve outstanding but it is necessary to do such research with appropriate design including different control groups (if not representative samples). If identification methods are used for selecting children for special programs, for example, at the very least, the levels of achievement which selected children are able to achieve with and without the program need to be examined, as well as the progress made by the non-selected with and without the program.

Therefore longitudinal studies with representative samples are extremely crucial for the evaluation of methods suited for the early identification of gifted

children. Unfortunately, such research is difficult to organize, expensive, and requires a great deal of manpower. A possible solution therefore could be to reanalyze data of big representative longitudinal surveys to obtain information on the usefulness of the identification methods (e.g. the British Birth Survey cited earlier). Such studies collect numerous variables on the motor and cognitive development as well as on the academic achievement of the children. Their size enables the investigation of groups of gifted children recruited without dubious screening by parents or teachers as has to be done in most giftedness studies for practical reasons.

Information obtained by checklists, however, have to be used carefully. Especially for young children, the competence of teachers to identify gifted children is often questioned (e.g. Fatouros, 1986) or nearly denied (e.g. Rost, 1993). Rost (1993) also judges peer and self nomination as totally useless for the identification of gifted (primary school) children (also Fatouros, 1986; Gagné, 1989). Although some authors argue that the best information on gifted preschool children is available from their parents (e.g. Hagen, 1989), according to the results of Johnson & Lewman (1990), parental perception of giftedness indicators in three- to four-year-old boys and girls has to be doubted, as the answers of parents showed drastic role stereotypes: While, in comparison with girls, boys are nominated considerably more frequently in the categories 'remarkable abstract thinking', 'extraordinary curiosity', and 'problem solving', while girls are perceived as possessing a 'large vocabulary' (30% more nominations).

If indicators of giftedness—for example in the form of (behavioral) checklists (Robinson, 1993; Stapf & Stapf, 1994)—are used, effective and practical statistical methods for the combination and weighting of the single information have to be used (see e.g. Hany, 1993). One possibility could be Bayes' rule which combines given probabilities of the occurrence of indicators in gifted and non-gifted children to evaluate the probability that a single child exhibiting some indicators and not exhibiting others is gifted. Modern statistics has provided more methods for combining probabilities. The mechanisms of these (e.g. the modern Shafer-Dempster theory) should be cautiously examined by practitioners and researchers.

At any rate, such combination of probabilities demands knowledge about the frequency of the indicator in gifted and unselected or non-gifted population (or in every group which is diagnostically relevant) and therefore necessitates respective research with representative samples. It should be noticed, that especially with indicators used for checklists, sometimes myths arise and are spread (e.g. Tannenbaum, 1992, cites a table from Lewis & Louis, 1991, who report that Freeman, 1985, found that gifted children are characterized by their sense of humor, although

Freeman, 1985, states the opposite; or see the section on sleep above).

As a quintessence, identification of young gifted children is problematic. Psychometric measures as well as diverse indicators of giftedness have up till now not proven to be suitable to identify these children which promise exceptional achievements later in school or in professional career. As early as 1896, the German founder of the experimental psychology, Wilhelm Wundt (1914) wrote: "The experimental method is almost without application for early childhood, and the results of experiments which have nevertheless been undertaken should be more or less considered purely coincidental because of the unbelievable weighting of error sources" (p. 364). Even if, nevertheless, much research with high standards has been undertaken, psychometric measures as well as diverse indicators of giftedness have, to date, not proven to be suitable for identifying those children who promise exceptional achievements later in school or in professional life.

Aside from possible principal obstacles to early identification, this is due to a considerable lack of appropriate research: There are too few prospective longitudinal studies and too few studies with representative samples or at least with adequate control groups (see Subotnik & Arnold, 1994). Giftedness research in young children too often fall back on to samples of counseling centers with their highly preselected clientele, thus finding and generalizing results which are not representative for the population of gifted children (see for example, the different results which Freeman, 1979, found for her gifted target and her gifted control group). In addition, too little effort in giftedness research is made in minority groups, in underprivileged children, in the handicapped, and in other risk groups. A possible way out of this dilemma could be the reanalysis of data from large surveys and other representative studies at least to generate hypotheses which can be tested in following giftedness studies.

Finally we have again to ask the question of why and for what purpose gifted children in infancy, preschool age or in the early elementary school years are to be identified. Usually answers refer to the danger that children who are not identified early are not adequately stimulated so that their gifts will not develop (e.g. Karnes & Johnson, 1990). Concerning infants and toddlers, however, Robinson (1987, 1993) is skeptical about the usefulness of early training to force the development of giftedness. Nevertheless the author draws the conclusion 'that successful parents are flexible, in tune with their children's progress, and ready to introduce a new idea when the child is ready, but that even those who are most planful also work with the children's own skills' (Robinson, 1987, p. 164). This means gifted children need stimulation, and they may require a variety of material so their intellectual needs can be fully met.

# Prediction of Excellence in School, Higher Education, and Work

Günter Trost<sup>1</sup>

## Introduction

How predictable is exceptional performance in school, higher education, and work? What is the predictive value of a variety of information gathered in a variety of ways with respect to excellence in these three areas? In attempting to provide answers to these questions by reviewing the literature, this contribution will focus on person-related predictors (abilities, motivation, further personality variables), while environmental factors will also be taken into account.

Before the empirical data can be reviewed, a brief discussion of the criterion referred to as 'excellence' seems appropriate.

## The Criterion of Excellence

'Excellence' is not a scientific term, and a clear-cut, unanimously accepted definition of it does not exist. In none of the standard textbooks on giftedness except one (Sternberg & Davidson, 1986) does the key-word 'excellence' appear in the subject index. Nevertheless, the term is frequently used in literature and mostly in the sense of outstanding achievement, brilliant performance, or 'eminence' (Hunt, 1983; National Commission on Excellence in Education, 1983; Feldhusen, 1984; Tannenbaum, 1986). Ochse (1990) uses the term 'excellence' in the title of her book as a synonym of creativity: "creative people excel—they go beyond what others have done" and "produce something of cultural value" (p. 3).

The borderline between 'excellence' and 'above-average achievement' has been drawn at very different points of the achievement continuum, depending on the author. Some set it extremely high, admitting only the epoch-making achievement of a genius brought forth once in a century. Others use listing in *Who's Who* as a criterion for that person's excellence, and still others rely on more or less exclusive awards or on peer nomination. Another approach is to define excellence

statistically, e.g. as achievement that can be measured on a discrete scale and exceeds a certain value, or as a characterization of persons who, when rank-ordered according to their respective accomplishments, reach positions beyond a certain percentile rank.

The small common denominator of all definitions is achievement far above average. Consequently, excellence can be observed in all domains of human performance. The scope of this chapter is restricted to the predictability of excellence in school, in higher education, and in work. (For a discussion about the methodological problems faced by empirical research into the determinants of excellence, see Subotnik and Arnold in this handbook.)

## Prediction of Excellence in School

Excellence in school, defined as outstanding overall achievement, can be measured by grade point average, by rank in class, or by teacher ratings. Excellent performance in particular subjects is reflected in top grades, teacher ratings, or achievement test scores. The predictors that have gained the most attention in this context are measures of intelligence, scholastic aptitude, creativity, interests, motivation, and other personality traits as well as parent and teacher ratings.

Lewis Terman (1925) started his famous longitudinal study in 1922 on 1,528 children who had scored at least 140 on an intelligence test before the age of 12; he and his co-researchers followed the persons in this sample over their entire life span. On an average, the highly intelligent children performed very well in school, but not exceedingly so (Terman, 1965).

In the context of the Munich Study of Giftedness (Heller & Hany, 1986; Perleth & Heller, 1994) the predictive validity of a battery of cognitive ability tests and creativity measures was determined on three samples of 11,13, and 15 year old secondary school students. The criterion was the average of school grades in German, mathematics, and English three years after the assessment of the predictor data. The validity coefficients for the combined test score were 0.48, 0.45, and 0.32.

<sup>1</sup> Institute for Test Development and Talent Research Ltd., Bonn, Germany. E-mail: ITB.GmbH@t-online.de

In the well-known Study of Mathematically Precocious Youth (SMPY) initiated by Julian Stanley and carried on under the directorship of Camilla Benbow, the predictive value of the quantitative section of the Scholastic Aptitude Test (SAT-M) with respect to high school achievement could be examined. The SAT-M proved to be a good predictor of excellent performance in mathematics and science, even when applied to 12-year-old students (Benbow & Minor, 1986).

Teacher ratings on achievement in a special mathematics course offered to gifted tenth-graders were the criteria in the Hamburg study on mathematically precocious youth carried out by Bix (1988). Among the predictors were the score in a German version of the quantitative section of the Scholastic Aptitude Test (GSAT-M) and the total score on an intelligence test. For two cohorts and a prediction period of two and three years, validity coefficients of 0.43 and 0.17 were found for the scholastic aptitude test score, and of 0.37 and 0.17 for the intelligence test score.

From the many studies covering the whole range of general cognitive abilities it can be concluded that intelligence and related ability test scores are satisfactory predictors of success in school with correlations around 0.40 to 0.50 (cf. Cattell & Butcher, 1968; Bloom, 1976; Parkerson et al., 1984; Kuusinen & Leskinen, 1988). The findings indicate, however, that even though high intelligence is a necessary prerequisite for top achievement in school, it is by far not sufficient. Other, non-cognitive factors are needed in addition (cf. Helmke, 1992; Schiefele et al., 1992).

Not surprisingly, teacher ratings turned out to be fairly good predictors of later achievement in school. In the Munich Study of Giftedness, a combined teacher rating of students' cognitive and creative abilities proved better than the combined results of a battery of ability and creativity tests as predictors of participants' grades in German, mathematics and natural sciences, assessed in secondary school after one-year and two-year intervals. In primary school the tests were superior to teacher judgments (Perleth & Heller, 1994). Denton (1986) reports good agreement between teacher ratings of excellent students and their classroom achievement two years later.

In a meta-analysis, Schiefele et al. (1992) examined the results of longitudinal studies from 18 countries that addressed the predictive validity of interest scales with respect to achievement in school, as measured by grades or achievement test scores. As this review includes a great number of studies initiated by the International Association for the Evaluation of Educational Achievement (IEA) using achievement tests with a fairly high ceiling as criteria, the authors' conclusions deserve to be mentioned here, even though the studies were not specifically focused on outstanding achievement. The mean value of 121 correlation coefficients was 0.31, after correction for attenuation it amounted to 0.40.

Basing their findings on the analysis of 40 studies, Uguroglu & Walberg (1979) reported an average coefficient of 0.34 for the correlation between measures of motivation and self-concept on the one hand and achievement in school on the other. Hansford & Hattie (1982), in their meta-analysis of data from 128 studies on the predictive validity of self-concept measures, found an average value of 0.21. In Bloom's study (1976), "self-concept of ability" was the strongest predictor of success in school among three types of self-concept. For 'affective characteristics' as predictors of school achievement, Fraser et al. (1987) found in their meta-analysis of 335 studies a mean validity coefficient of 0.12.

In sum, the findings suggest that teacher ratings, cognitive tests, and measures of non-cognitive features such as interests, motivation, and self-concept can be used for the prediction of outstanding achievement in school and that they should be used in combination. What the optimal combination is cannot be derived from the available data; however, cognitive abilities far above average seem to be indispensable for excellence in school.

There is only indirect evidence as to the contribution parent ratings can make to the prediction of outstanding achievement in school. Jacobs (1971) and Ciha et al. (1974) report findings indicating that parents are reasonably successful in identifying gifted children. Other studies raise doubts about the predictive value of parent judgments (e.g. Ferdinand, 1961; Miles, 1965). In general, parents tend to overestimate their children's giftedness (Ferdinand, 1961), while highly-educated parents tend toward underestimation (Martinson, 1975). In all, parent ratings do not seem to be very valid predictors of achievement in school. However, parents are apparently in a position to identify, at an early stage of their children's development, high potential in music or in the arts (Sloane & Sosniak, 1985; Sosniak, 1985a).

### Prediction of Excellence in Higher Education

Excellence in higher education can be operationalized by outstanding grade point averages or marks in intermediary or final examinations as well as by awards and honors degrees. It was possible to follow up on the participants in the above-mentioned Study of Mathematically Precocious Youth (SMPY) for another five years after graduation from high school. They had been selected at age 12, primarily on the basis of above-average performance on the quantitative section of the Scholastic Aptitude Test that had been designed for a much older age group (Stanley & Benbow, 1986). As college graduates, almost half ranked among the top 10% of their class, 11% reported awards or honors in mathematics, 10% in science (Benbow & Arjmand, 1990; Lubinski & Benbow, 1994). The canonical correlation for the SAT-M—when administered at high school age—as a predictor of university achievement

was 0.30. Other important predictors were attitude toward mathematics and science, encouragement to pursue academic and career goals, and paternal educational level (Benbow & Arjmand, 1990).

In a four-year follow-up study of 1,200 German students who had ranked among the top 10% in the final class of upper secondary school, low but highly significant correlations were found between grades in the 12th school year and grades on the first university examination (0.25), and also between the total score in a scholastic aptitude test and the same criterion (0.16). Forty per cent of those whose test scores were in the top quartile within the pre-selected group subsequently earned top grades at university (Trost, 1986).

Chauncey and Hilton (1965) examined validity studies on samples of highly able students. They concluded that scholastic aptitude tests can discriminate reliably even among very gifted students and predict their academic performance.

Willingham (1985) summarizes his review of empirical data on the predictability of success in college as follows: "The two traditional academic predictors, high school rank (HSR) and admissions test score (SAT) were by far the best at forecasting the scholastic types of achievement. In a comparison of the two, HSR was a somewhat better predictor of college honors (based on cumulative grade average), while the SAT was a somewhat better predictor of departmental honors. The latter were based on independent scholarship, arguably more characteristic of pre-professional work in the discipline than is grade point average" (p. 179). Willingham also presents data demonstrating that both high school records and scores on the Scholastic Aptitude Test have their highest predictive validities within student sub-samples above the 90th percentile (p. 29). In a more recent survey Lubinski & Dawis (1992) came to similar conclusions.

There is also some evidence of the relationship between superior intelligence and outstanding achievement in higher education. Hollingworth (1942) studied the educational development of 12 children up to their early twenties who had scored 180 or above on the Stanford-Binet intelligence test before the age of 12. They did exceedingly well in college and won a long list of prizes and honors.

Feldman (1984) identified those 26 persons in Terman's group of highly intelligent children with IQs above 180 and compared their educational careers with those of 26 subjects selected at random from Terman's original group of 1,500. On the whole, both groups were highly successful throughout their college years, with a markedly larger percentage of persons winning honors and receiving advanced degrees in the above-180 IQ group. For his total sample of highly intelligent persons Terman (1965) reports that "close to 90% entered college and 70% graduated. Of those graduating, 30% were awarded honors and about two-thirds remained for graduate work" (p. 12).

The relative importance of non-cognitive factors for achievement in higher education has been demonstrated in various studies (see, e.g. the reviews by Lavin, 1965; Cattell & Butcher, 1968; Khan, 1969; Mabe & West, 1982; Steinkamp & Maehr, 1983; Schiefele, Krapp & Winteler, 1992).

Nichols & Holland (1963) and Nichols (1966) attained considerable improvement in the prediction of college grades of a highly selective sample of finalists and scholars of the National Merit Scholarship program when they included attitude, interest, and personality scales in the set of predictors: "For predicting college grades, high school grades were the best predictor (average validity 0.33), followed by the non-intellective scales (average validity 0.27), and finally by the aptitude test (average validity 0.12)" (Nichols, 1966, p. 911).

The overall conclusions which may be drawn from the findings on the predictability of excellence in higher education are: achievements in secondary school and performance on scholastic aptitude tests are the best predictors; high scores on intelligence tests also have satisfactory predictive validity. Other factors, particularly interest, motivation, and self-concept, have, on their own, a lower predictive power. However, they do add to the overall prediction of academic success, and among highly intelligent students, these factors seem to differentiate between the very good and the excellent.

### Prediction of Excellence in Work

Authors operationalize excellence in work in a variety of different ways including: recognition as geniuses who have revolutionized their fields in some way, distinguished awards persons have won for their work, outstanding ratings by experts in the field, high number of publications, patents, or exhibitions, etc.

One of the ways to uncover the determinants of excellence in work is analyzing biographies of eminent persons. The first study of this type was Sir Francis Galton's work on 'hereditary genius' (1869). He found three common elements: capacity, zeal, and the power of hard work. His study on eminent scientists (1874) led to the conclusion that "these people were endowed with superior intellectual ability, tremendous energy, good physical health, a sense of independence and purposefulness, and exceptional dedication to their fields of productivity", as Tannenbaum (1986, p. 27) summarizes.

As part of Lewis Terman's genetic studies of genius, Catherine Cox (1926) reported on the early development of 300 famous persons from the past 450 years who had made outstanding contributions to their cultures. The sample included Byron, Cromwell, Darwin, Kant, Luther, Michelangelo, Mozart, Newton, and Robespierre. From the information given in the biographies, estimates were made as to the persons' IQs and more than sixty other personal traits. Within

her sample, Cox compared a subgroup of the most creative subjects with the total group. The intelligence ratings assigned to the persons in the total sample were high: for the subgroup of eminent philosophers the average IQ estimate in childhood was 173, for the scientists 164, for the statesmen 159, and for the soldiers 133. However, the estimated IQ did not differentiate between high and exceptionally high achievement. Cox concluded from her data that given high intelligence, persistence, motivation, and effort influence whether the highest level of accomplishment will be achieved or not. Other features that she found particularly characteristic for the 100 leading geniuses in her sample were confidence in their abilities, and 'strength of character' (p. 50).

Twenty-five years after the Cox study, Anne Roe (1952a, 1952b, 1953) selected, on the basis of nomination by panels of experts in each field, 64 of the most eminent living American scientists: 20 biologists, 22 physicists, and 22 social scientists (psychologists and anthropologists) and examined them comprehensively by interviews and tests. Although there were marked group differences between the natural scientists and the social scientists, and between the biologists and the physicists, certain common patterns did appear in the group as a whole.

The scientists typically came from middle-class and upper middle-class families. Of the individuals surveyed, 53% were the sons of professionals, another 19% the sons of businessmen. Learning for its own sake was highly valued in their families. They developed early independence, read a lot, and enjoyed school and university. The intelligence level of the eminent scientists—as measured at the time of the study—was very high, their average scores in verbal and quantitative tests corresponding to an IQ of approximately 160. Furthermore, the interviews revealed that one of the features all 64 eminent scientists had in common was the "driving absorption in their work" (Roe, 1952a, p. 25).

MacKinnon (1960, 1978) conducted a series of both retrospective and cross-sectional studies on creative architects, engineers, industrial researchers, mathematicians, physical scientists, and writers nominated by experts in the fields. Apart from features that were characteristic to each of the respective groups, he found the following traits common among the highly effective persons in all of these fields: openness to experience, independence in goal-setting, enthusiasm, and high tolerance for frustration in the course of solving problems.

Goertzel & Goertzel (1962) and Goertzel et al. (1978) examined the biographies of 314 eminent personalities of the twentieth century, stressing environmental rather than individual factors. Their results confirmed many of the previously mentioned findings. In contrast to other authors, however, they found that 85% of the eminent persons came from disturbed

homes. Nevertheless, parents—as well as other mentors—seemed to play a significant role in evoking the children's and adolescents' motivation to achieve.

Walberg et al. (1981) asked biographers working for the *Encyclopedia Britannica* to rate the presence or absence of traits in the childhood of those persons from Cox's sample whose biographies the authors had written. According to the ratings, the most distinctive trait common to 97% of the 221 eminent men was intelligence; they also had superior communicative skills. Eighty-two per cent were permitted by their parents to explore environments on their own. Eighty per cent were very successful in school.

Simonton (1984, 1987) re-analyzed the Cox and the Goertzel family data. According to his findings, the eminent persons came from intellectually and culturally stimulating homes; they acquired numerous demanding hobbies and were omnivorous readers. In their later educational and professional careers they displayed immense productivity. Simonton also gathered evidence that "intelligence is the single best personological predictor of leadership in general" (1988, p. 399). For all subgroups of eminent persons except for "celebrities" (including athletes, businessmen, editors, and performers) he found an inverted U-shaped curve for the relation between attained educational level and eminence.

A series of retrospective studies on 120 living persons who, before age 40, had attained distinction as concert pianists, sculptors, swimmers, tennis-players, research mathematicians, and research neurologists was carried out under the directorship of Benjamin Bloom (1985). Interviews with the individuals and their parents revealed a number of communalities over the groups under study. The majority of the parents placed high value on achievement, success, and persistence at work. They encouraged and supported the interests their children pursued and were willing to devote time, resources, and energy to providing the best conditions for the development of their children's talents. They viewed their children as gifted and expected hard work and high attainments from them. In terms of parental interests and activities the climate was consistently favorable: the parents of the swimmers and tennis-players were interested in athletics (Kalinowski, 1985; Monsaas, 1985); in the homes of the concert pianists music played an important part (Sosniak, 1985a); there was a certain emphasis on the arts in the sculptor's homes (Sloane & Sosniak, 1985); the parents of the mathematicians and neurologists had themselves attained high levels of education and offered a wide range of intellectual stimulation to their children (Gustin, 1985; Sosniak, 1985b).

The children can be characterized as rather self-guided and independent in their interests and activities; they had soon become highly self-confident with respect to their abilities. In their adolescence they were strongly motivated to learn, to practice, and improve

upon their accomplishments. The academic records of the pianists, sculptors and athletes were inconspicuous; those of the research neurologists were very good but not necessarily brilliant; most of the research mathematicians had attained excellent results both in secondary and higher education.

Harriet Zuckerman (1977) examined the biographies of 92 Nobel laureates, partly by means of interviews, and concluded that their socio-economic backgrounds were considerably higher than those of 'non-eminent' scientists, that they were significantly influenced by role models ('elite masters') and had a particularly high level of self-confidence.

Several retrospective studies comparing exceptional managers with average managers yielded fairly consistent results as to the predictors of outstanding managerial achievement: superior cognitive abilities, high interpersonal skills, vigorous desire for achievement, and strong self-confidence (Klemp & McClelland, 1986; Cascio, 1987; Northouse, 1997).

While the studies mentioned so far were designed as retrospective analyses, other studies started with more or less selected samples of children or adolescents who were followed up until life achievement could be measured.

The most famous longitudinal study of this kind, is the one by Lewis Terman begun in 1922 with a sample of 1,528 six- to twelve-year-old children with IQs of at least 140 (Terman, 1925). The 800 males in his sample (only a minority of the women had pursued professional careers at that time) developed impressive records of adult life achievement: "By 1950, . . . they had published 67 books, . . . more than 1,400 scientific, technical, and professional articles; over 200 short stories, novelettes, and plays. . . . They had also authored more than 150 patents. . . . Of the scientists, 47 are listed in the 1949 edition of *American Men of Science*. Nearly all of these numbers are from 10 to 20 or 30 times as large as would be found for 800 men of corresponding age picked at random in the general population" (Terman, 1965, p. 12). According to Terman, these figures prove that tests of general intelligence, given at school age, "tell a great deal about the ability to achieve either presently or 30 years hence" (1965, p. 13). Notably, the 150 most and the 150 least successful men in the sample did not differ in their average measured intelligence. They did, however, differ in personality traits such as "persistence in the accomplishment of ends, integration toward goals, self-confidence, and freedom from inferiority feelings, all-round emotional and social adjustment, and . . . drive to achieve" (Terman & Oden, 1959, p. 148).

By comparing the professional careers of the 26 persons from Terman's sample—persons who, before age 12, had scored above 180 in the intelligence test—with the careers of a control group of 26 persons drawn at random from the same sample, Feldman (1984)

found only "some margin of benefit from the extra IQ points" (p. 520) in terms of professional achievement.

Tomlinson-Keasey & Little (1990) factor-analyzed data gathered by Terman—parent and teacher trait ratings from the year 1922, family of origin characteristics described retrospectively by the subjects, and variables of adult accomplishment—and represented the relationships in a path model. Of all the 'early' predictors, the factor 'parental education' showed the highest correlation to the criterion factors 'educational attainment' (0.26) and 'occupational achievement' (0.13).

In another re-analysis of the Terman data, Walberg et al. (1994) differentiated between relatively fixed and relatively alterable predictor variables. They found that alterable variables (e.g. hours of instruction, health, leisure activities) contributed little to the prediction of educational and occupational outcome beyond that already afforded by the fixed variables (including abilities and socio-economic status).

Two studies carried out recently at the Institute for Test Development and Talent Research in Bonn, Germany deserve mention in this context. Heilmann (1999) investigated the educational and professional careers of all national winners of the German Federal Mathematics Competition for grades 11–13 since 1971, the year the competition was introduced. Every year, some 10 national winners emerge from a total of 1,600 participants. In her retrospective analyses Heilmann included several control groups: One was a sample from the most selective German scholarship program for highly gifted university students, matched to the 'winners' group in terms of age, gender, and choice of courses in higher education. Another comparison group consisted of a representative sample of 2,220 persons—matched to the 'winners' group with respect to gender—who had graduated from upper secondary school in 1973 and had been followed up since that year in a longitudinal study (Trost, 1987).

The winners' parents offered their children significantly more support than the parents of the students in the representative group, both in terms of assistance in developing their abilities and pursuing their interests, and in terms of emotional warmth. As to the parents' academic backgrounds, the proportion of parents who held university degrees was nearly three times as high for the mothers of the winners and nearly twice as high for the fathers of the winners than for the mothers and fathers of the persons in the representative group.

Throughout school age the winners were highly committed to working on mathematical problems and earned top grades in mathematics. It should be pointed out that their performance in other subjects was also exceptional: Their average grade in the school-leaving certificate ranged more than two standard deviations above the average grade of the representative group. Of the winners, 1 in 6 had skipped one school year, as

compared to 1 in 12 National Merit scholarship recipients and 1 in 63 members of the representative group. With respect to extra-curricular interests during the school years, the 'winners' differed from the 'scholars' in that the latter were much more interested in the political/social field (comparable data for the representative group was not available).

A comparison of the career-related motives and values of the groups under study yielded marked discrepancies. The career goals of the representative group were more 'extrinsic' in nature (earning money, job security), and associated with social values (working for changes in society, working on a team). The winners clearly favored 'intrinsic' aims (tackling challenging tasks, pursuing personal interests, contributing to progress in personal area of specialization).

The Mathematics Competition winners' post-secondary careers are characterized by outstanding achievement: they earned top grades in university, 81% completed their doctoral dissertations (representative group: 12%) and they were, on average, two years younger than the persons in the representative sample upon receipt of their doctoral degrees. The 'winners' group was able to list about three times as many indicators of success in science and technology (e.g. number of publications, participation in inventions, awards) as the representative control group.

In another retrospective study, Sieglen (1998) identified 121 adults who have been exceptionally successful as scientists (41), engineers (40), and businessmen (40). Here the control group consisted of a nationally representative sample of about 3,600 Germans who had graduated from secondary school in 1973—persons who had been included in the same long-term follow-up study that provided control data for Heilmann's 1999 investigation.

The outstanding scientists, engineers, and businessmen differed from the representative group with regard to a variety of features characterizing their behavior and motives at school age, during the period of higher education, and at the time of their entry into professional life, as well as their home environments. The patterns were very similar for outstanding scientists and engineers while the outstanding businessmen differed largely in other respects from the unselected control group.

At school age, both the outstanding scientists and engineers developed scientific curiosity, perseverance, concentration, and a desire to seek intellectual challenge to a much greater extent than the control group; they also had a wider range of interests. Their academic achievements both in school and in higher education were far beyond those of the representative group, and their career motives were much more achievement-oriented and 'intrinsic'. The outstanding managers also differed from the control group in terms of the desire to seek intellectual challenge at school age; their academic achievements, however, were not distinctly

superior. The aspects most significantly distinguishing this top group from the representative group at school age were the striving to influence others and the ability to take initiative. With respect to career motives, the outstanding businessmen were—like the scientists and engineers—achievement-oriented and 'intrinsically' motivated; at the same time they differed from the control group to an even greater extent in their appreciation of the 'materialistic' rewards of their work and in their general professional ambitions. In terms of home environment and parental support, the three top groups differed from the representative group much less than they did in terms of the aspects mentioned above.

To sum up, the evidence gathered from these two recent studies emphasizes the relevance of individual predictors such as cognitive abilities, interests, and motives as well as academic achievement for exceptional performance in the professions. The results also support the notion of 'differential predictability': The sets of information that prove to contribute best to the prediction of outstanding success in differing career paths are to some extent themselves different, i.e. whereas a certain set of abilities, interests, or motives is best suited for prediction of excellence in one domain, a partially or wholly different set of traits may be the best predictors in another, etc.

Torrance (1988) also conducted longitudinal studies on unselected groups. He operationalized 'creative adult achievement' as "quantity of publicly recognized and acknowledged creative achievements" and "quality of creative achievements" (p. 58) according to three judges' quality ratings of what the subjects had identified as their most creative achievements. For a sample of 254 high school seniors who had taken creativity, intelligence and school-based achievement tests in 1959 and were followed up until 1979, Torrance (1988) obtained the following correlations with the quantitative and the qualitative criteria of adult creative achievement respectively: 0.32 and 0.36 for the total score in the creativity test battery, 0.21 and 0.38 for the total intelligence score, and 0.27 and 0.47 for the total achievement test score. For another sample of 211 subjects tested at elementary school level and followed up for 22 years, Torrance found validity coefficients of 0.46 for the total creativity score with respect to the quantitative criterion and 0.58 with respect to the qualitative criterion of achievement.

Empirical findings as to the predictability of job success in general (i.e. not only in view of excellence) complete the picture. The results of a meta-analysis indicate that overall cognitive ability is the best single predictor with an average correlation coefficient of 0.45 (Hunter & Hunter, 1984). The correlation between college grade-point average and job success is considerably lower, the average correlation coefficient being 0.30 (Roth, BeVier, Switzer & Schippmann, 1996).

Among non-cognitive variables, biographical data on past attainments in particular areas tend to be the best predictors of similar attainments in adult life, the mean validity coefficient being 0.37 (Taylor & Ellison, 1967; Hunter & Hunter, 1984). The predictive validity of interests as measured by questionnaires is lower, the respective values ranging around 0.20 or below (Hunter & Hunter, 1984). The relation between general personality traits as they are assessed by personality inventories and measures of job success seems to be rather weak: the average correlation coefficient amounts to 0.15 (Hunter & Hunter, 1984; Klitgaard, 1985).

### Summary and Conclusions

What, then, are the characteristics which can be assessed at earlier stages of a person's life that contribute to the prediction of excellence at later stages? In the first place, the results of all pertinent research clearly show that there is no such thing as one exclusive predictor of outstanding achievement. Instead, excellent performance is the product of a highly complex intra-individual interaction of a variety of traits (cognitive and non-cognitive abilities, motivational and emotional attributes, additional personality variables), as well as of an interaction between these individual traits and environmental factors (influences of family, peers, school, university, extra-curricular experiences, the media, etc.). The prevailing conceptions of giftedness as they are proposed, for instance, by Feldhusen (1986), Gagné (1991), Heller (1989) and Tannenbaum (1986) emphasize these interactions and thus are in line with the findings reported in this chapter (see also Gagné; Hany & Weinert; Ziegler & Heller in this handbook).

Second, there is hardly any single predictor that accounts for more than 30% of the variance in any criterion of achievement if predictors and criteria are measured in longitudinal studies. In cross-validation studies, even optimal combinations of several predictors rarely explain more than 50% of the variance in later achievement. These figures reflect the degree of predictability of achievement in unselected populations where the full range of individual achievements, from very low to very high, can be observed. In cases of highly selected groups where we aim at predicting extraordinary performance, our expectations concerning the degree of predictability must be placed even lower. One of the reasons for this is the restriction of variance with regard to both the predictors and the criteria, a circumstance that tends to diminish the correlations between the variables under study. It is therefore safe to say that, even by using the best predictors available (both individual and environmental) and combining them in the most appropriate way, less than half of 'what makes excellence' can be accounted for (see also Subotnik & Arnold in this handbook).

Within these limits, though, certain variables have fairly consistently proved to be more predictive than others. For a large number of areas of excellence, intelligence and other cognitive abilities are the most important single predictors, particularly in terms of outstanding performance in school, in higher education, in vocational training, in the professions, in business, and in all fields of scientific research. "It appears that individuals who end up known in history as highly productive achievers in those fields requiring extensive formal schooling are likely to have an IQ of at least 145" (Albert & Runco, 1986, p. 349). Other abilities, e.g. psychomotor, perceptual and social abilities, hold the highest rank positions as predictors of exceptional performance in sports, in the fine arts and the performing arts, in music, and in some areas of leadership. Abilities assessed by tests are better predictors than abilities rated by parents or teachers, at least in the cognitive domain. Whenever the accomplishment of something novel is the criterion, creativity is an important additional predictor. However, a fairly high, though not exceptional level of intelligence is also necessary for high degrees of creative achievement (Roe, 1952b; Cattell, 1963; Barron, 1969).

Although the predictive value of specific abilities can be different, depending on the particular domain of achievement, some motivational, affective, and environmental characteristics are obviously relevant predictors across domains. Aside from ability variables, a high and task-oriented motivation is probably the most powerful predictor of excellence. Its importance has been confirmed in practically all studies searching for the determinants of outstanding achievement. Aspects of it are the willingness to work hard and persistently on things that are of particular interest to the individual, perseverance in the face of obstacles, a high level of aspiration, competitiveness, and ambition. High motivation without high abilities will not bring about extraordinary accomplishments; inversely, even persons endowed with maximum abilities but who lack 'task commitment' (Renzulli, 1986) will never excel.

The connecting link between ability and motivation seems to be the individual's self-concept, another relevant predictor of excellence. It is a set of perceptions and evaluations of one's own traits. Persons characterized by outstanding accomplishments were, as a rule, quite aware of their extraordinary capabilities at the time of their childhood and adolescence. As a consequence, their self-confidence was boosted which encouraged them to set their stakes higher and improve their achievements.

There are some further personality traits in which persons who later excel, be it in their educational records, their extra-curricular achievements, or their vocational accomplishments, already differ from their peers in childhood and adolescence. One of them is independence, both emotionally and intellectually. They are more self-directed in setting their goals and in

choosing the objects of their activities and the problems they are going to tackle; they are more willing to work alone and to accept responsibility for their products. A tendency toward non-conformity, unconventionality, even radicality of thinking goes along with this independence. However, the predictive validity of these personality traits, as they are assessed by interviews or questionnaires, is not very high.

Interests as measured by inventories can make a useful contribution to the prediction of outstanding achievement. They are obviously domain-specific predictors; in general, the predictive validity of interests is considerably lower than the validity of abilities.

Lastly, there are some aspects of the home environment that can serve as predictors of excellent achievement, not as isolated factors but rather as 'catalysts' (Gagné, 1991), aiding in the gradual manifestation of potential and development of abilities. One relevant aspect is the parents' value system: Positive attitudes toward learning, practice, and achievement in general shape and foster children's achievement motivation. A second aspect is exposure to a variety of experiences—e.g. frequent discussions, shared hobbies and other leisure time activities—serving the children as incentives in the discovery and development of their own interests and abilities. A third aspect is the relative freedom with which the children are allowed to pursue their interests. The fourth relevant contribution is the parents' support for the development of their children's abilities. In the course of adolescence and thereafter, the importance of the home environment diminishes as the influence of role models outside the home increases; it has been pointed out earlier that virtually all of the research data leading to these conclusions were obtained retrospectively. The degree to which information on the home environment can contribute to the prediction of excellence in longitudinal studies is presumably very modest, for two reasons: first, the home environment is a moderator rather than a genuine predictor variable; second, it is difficult to assess reliable indices of the situational factors mentioned above.

A further group of predictors might be called 'second-order predictors', as they are in a sense both predictors and (early) criteria of achievement: performance in school, in higher education, and extra-curricular accomplishments during all stages of education. Quite naturally, past achievement is the best predictor of similar future achievement. This is why teacher ratings of classroom performance are good predictors of school grades, school grades are good predictors of college grades, early accomplishments in sports, music or the arts are good predictors of later accomplishments in the same areas, etc., especially in the upper part of the achievement continuum. Both society and researchers, however, have a keen interest in identifying the potential of (future) outstanding performance at a point in time when high accomplish-

ment in the respective (or closely corresponding) area cannot yet be observed. Where this is the case, there is no choice but to try and assess the individual traits (abilities, motivation, interests, self-concept) and the environmental predictors discussed above.

### An Outlook

Much has been done to uncover the predictors of excellence since Galton set out to study geniuses more than a century ago. Several interesting investigations have been carried out since the first edition of this handbook appeared in 1993; yet much remains to be done. Most of the knowledge available on this subject has been gathered by means of retrospective studies; throughout the history of research into giftedness, longitudinal studies have been scarce. It seems, however, that within the past decade or so efforts to conduct longitudinal research have been increasing (see Subotnik & Arnold and Ziegler & Heller in this handbook). Still there is a need for more long-term longitudinal studies based on large unselected samples and assessing a broad spectrum of predictor variables. In cases where the samples have already been highly selected, unselected control groups ought to be included. In the latter respect, progress has also been made since the handbook was first issued.

Better assessment instruments are needed as well: instruments such as complex tests of information processing and problem solving, with good discriminative power in the upper range of the performance continuum. Computer-based adaptive ability tests and complex problem scenarios we already have at our disposal should be further developed and applied to investigations of the predictability of exceptional performance. In addition, we require more reliable instruments for assessing the motivational, affective, and environmental variables that have proved essential for outstanding performance.

Finally, more use should be made of methods for modeling the complex interactions of predictors and their relationships to achievement criteria (see, e.g. Jöreskog, 1979). To date, few researchers have applied such structural models to the analysis of longitudinal data on the predictability of extraordinary achievement.

With the help of longitudinal studies, better instruments of assessment, and the application of complex structural models to longitudinal data, we can further enhance our understanding of the sources of outstanding achievement and thus create a more solid basis for the identification and support of individuals with extremely high potential.

# Conceptual Foundations and Theoretical Lenses for the Diversity of Giftedness and Talent

LeoNora M. Cohen<sup>1</sup>, Don Ambrose<sup>2</sup> and William N. Powell<sup>3</sup>

Conceptual foundations include definitions and conceptions of giftedness; philosophical bases and ethical issues; theories and models; historical, social, political, and economic considerations; influences from outside the field; and trends, issues, and future directions for the field. Other chapters in this book deal with some of these aspects, particularly chapters by Tannenbaum, Heller and Ziegler, Simonton, Gagné, and Monks and Mason. This chapter will therefore focus largely on philosophical and theoretical considerations.

Philosophical frameworks and theoretical lenses provide guidance for coordinating meaningful research and for building coherent practices in gifted education. Without a solid conceptual base and theoretical awareness, researchers and practitioners tend to develop conceptual blind spots and ignore important aspects of giftedness and talent. Worse still, they can perpetuate current socio-political power structures and give no voice to the gifted in under-represented groups.

These blind spots arise from tacit entrapment within dominant philosophical frameworks or favored theoretical perspectives. For instance, mechanistic philosophical beliefs (reality as machine-like) encourage assumptions that intelligence is objectively measurable and culture-transcendent. Such assumptions obscure alternative conceptions of intelligence and perpetuate long-established sorting practices that ignore gifts and talents valued by minority populations. At their worst, these practices have reinforced the power of dominant classes, while promoting exploitation, racism, and even eugenics policies (Powell, 1999). The prominence of these assumptions and practices in the historical development of gifted education eventually led to the quagmire in which the

field currently finds itself, namely, under-inclusion of children from racial and ethnic minorities and impoverished groups (Passow & Frasier, 1996; Rudnitski & Kearney, 1996).

Gifted education is still based on dominant-culture conceptions of giftedness. What continues to be ignored are ways to understand and define giftedness and talents of non-mainstream children outside of the dominant hierarchical social order. Their gifts and talents may be overlooked, according to Passow & Frasier (1996), due to overemphasis on standardized tests, narrow definitions of giftedness, failure to consider attributes and specific behaviors in cultural context, deficit orientations, and lack of dynamic assessment through learning opportunities. This is in spite of major focus in the field in the 1960s and 1970s and efforts by Frasier, Garcia, and Passow (1995), Frasier et al. (1995), Ford (1996), Ford & Harris (1999), Maker (1996), Maker and Schiever (1989), Peterson (1999) and others to conceptualize giftedness in diverse groups and to identify and serve diverse children.

Although there has been some progress in developing conceptual underpinnings for the field of gifted education, the issue of diversity has not yet been sufficiently addressed. Several researchers and practitioners have focused on addressing under-represented groups, particularly the identification of children from these groups, but there has been little attention to the related theoretical or philosophical dimensions of the field that shape exclusionary, possibly Eurocentric definitions of giftedness and talent.

Theorists, researchers, and practitioners need to critique their own assumptions in efforts to ensure that they are not ensnared in insular, ethnocentric thinking about giftedness and talent. One way to carry out such a critique is to explore the philosophical and theoretical roots of thinking in the field. Another is to look beyond the borders of the field to discover research findings, theoretical frameworks, and philosophical perspectives that can reveal new ways of thinking about optimal development of creativity, intelligence, and other aspects of children's potential. This chapter is

a broad-based exploration of conceptual foundations and theoretical lenses for the diversity of giftedness.

### **Current Fragmentation and Incoherence of Approaches to Education of the Gifted and Talented**

Reflection about the core assumptions and the evolution of the field has been emerging (see Ambrose, 1998a, 1998b; Ambrose, Cohen & Coleman, 1999; Borland, 1990, 1996; Callahan, 1996; Cohen, 1996; Coleman, Sanders & Cross, 1997; Gallagher 1996; Pendarvis & Howley, 1996). Much of this deliberation has to do with equity issues, perceived lack of purpose, and qualitative differentiation concerns in quick-fix programming and instruction, as well as the viability of gifted education per se. Attacks from outside the field (e.g. Oakes, 1985; Sapon-Shevin, 1994; Margolin, 1996) have catalyzed some of this reflection.

In spite of the development of several excellent conceptual models (e.g. Benbow, 1986; Betts, 1985; Clark, 1992; Feldhusen, 1998; Gagné, 1993; Jellen and Verduin, 1986; Kaplan, 1986; Milgram, 1989; Piirto, 1999a; Renzulli, 1986, 1994; Renzulli & Reis, 1985; Tannenbaum, 1983, 1986; Taylor, 1986; Treffinger & Sortore, 1994; VanTassel-Baska, 1992; Ward, 1980), simplistic approaches to programming and instruction are too often implemented with the claim that they are specifically designed for the gifted. Yet these 'easy' approaches pay little attention to the nuances of, or rationale for, these models. Practices disconnected from strong, conceptual underpinnings open gifted education to criticism. Even though important meta-analyses have clarified research-practice connections (e.g. Shore, Cornell, Robinson & Ward, 1991; Kulik & Kulik, 1992; Rogers, 1992), justification of qualitatively different programming and practices for gifted children is built on shifting sands due to a lack of coherent theory and philosophical awareness. Moreover, the needs of children from diverse cultures and socio-economic backgrounds remain obscured.

#### *Limitations of Research*

Research paradigms partially determine what will be studied in a field (Ambrose, 1998a; Borland, 1990; Coleman, Sanders & Cross, 1997; Lincoln & Guba, 1985). For instance, the positivistic paradigm biases research toward analytic investigation of decontextualized variables while the post-positivist paradigm embraces the complexities of context. The contexts for gifted education include the larger school system and the socio-economic, political, and cultural aspects of society. If most of the research in a field is positivistic, that field may ignore important contextual influences.

Renzulli (1991) points out that the dominance of traditional research designs and instruments limit what can be studied in gifted education, and that this obscures visibility of the needs of minority and

economically-disadvantaged groups. Cross (1994) notes that gifted education lags behind general education in the employment of alternative research methods (e.g. constructivism, critical theory, or varied qualitative methodologies). The dominance of the traditional research paradigm, he claims, protects the research base from unconventional ideas, data, and theories. In addition, research in the field has been largely atheoretical, dealing with small issues often in a piecemeal approach that misses the whole picture. Without theoretic guidance, the 'so what' of research does not become integrated into practice (Cohen & Ambrose, 1993).

### **Philosophical Underpinnings of Gifted Education**

One reason for fragmentation and insularity of theory, research, and practice in the field is that opposing world views tacitly influence the thinking of scholars and practitioners at the philosophical level. World views are broad, meta-theoretical conceptual lenses based on root-metaphorical filters through which individuals perceive reality (Gillespie, 1992; Overton, 1984; Pepper, 1942). These world views, which include mechanism, organicism, contextualism, and formism, implicitly shape basic assumptions about theory, research, and practice.

Tacit entrapment within the conceptual framework of one world view can cause scholars and practitioners to misunderstand or devalue the work of others whose world views differ from their own. The broad scope of each world view can mislead a scholar or practitioner into thinking that his or her perspective provides a sufficient view of the whole, but each world view highlights some aspects of phenomena while obscuring others. For example, the mechanistic view, based on the root metaphor of a machine, encourages perceptions of reality as stable and fixed, predisposing researchers to reductive analyses and the search for the simplest cause-effect explanations. It promotes reductive conceptions of mind, such as behaviorist theory or strictly inside-the-cranium computer metaphors of mind, while denying the validity of holistic or contextual accounts.

Actually, each world view has sufficient breadth of scope to provide useful alternative explanations, and complex phenomena require multiple investigations based on more than one world-view (Ambrose, 1996, 1998a; Gillespie, 1992; Overton, 1984; Pepper, 1942). Table 1 provides an overview of the essential characteristics of the world views, their connections with well-known philosophical paradigms, and some examples of their influences on conceptual foundations.

### **Paradigm Shifts in Gifted Education**

An investigative paradigm is a collection of implicit assumptions that influences scientific research and shapes the formation of theories and conceptual models (Kuhn, 1970). Treffinger & Sortore (1994) claim that

Table 1. *Root-Metaphorical World Views: Their Tenets, Limitations, and Influences on Conceptions of Giftedness* © 1999 Don Ambrose.

World View	Organicism	Contextualism	Formism	Mechanism
Root metaphor	<ul style="list-style-type: none"> <li>- Organism developing through stages toward a particular end</li> </ul>	<ul style="list-style-type: none"> <li>- Ongoing event within its context</li> </ul>	<ul style="list-style-type: none"> <li>- Similarity</li> </ul>	<ul style="list-style-type: none"> <li>- Machine</li> </ul>

Preferred mode of inquiry	<p><b>Postpositivist:</b></p> <ul style="list-style-type: none"> <li>- Seeks big-picture, qualitative essence patterns in multiple interpretations (constructed realities) of complex, holistic phenomena.</li> <li>- Assumes that elements and processes in these phenomena are inextricably intertwined, mutually shaping, and inescapably influenced by context</li> <li>- Assumes inseparability of researcher and the object of study. Clarifies values and biases of the researcher on assumption that research is not value-free</li> </ul>			<p><b>Positivist:</b></p> <ul style="list-style-type: none"> <li>- Seeks prediction and control of linear cause-effect relationships between isolated variables</li> <li>- Uses objective, value-free experimental, quantitative analyses</li> </ul>
Examples of research projects primarily influenced by the world view	<ul style="list-style-type: none"> <li>- In a case study of a creative individual, a researcher seeks ways in which intrasystemic, mutually shaping interactions among cognitive, affective, and conative subsystems promote long-range purpose</li> </ul>	<ul style="list-style-type: none"> <li>- Qualitative researcher seeking effects of socioeconomic influences on talented minority children who show resilience in dealing with unpredictable environments</li> </ul>	<ul style="list-style-type: none"> <li>- Complexity theorists discovering patterns of similarity in the dynamics of human brains and the US economic system</li> <li>- Philosophical analysis of metaphors that underpin research in gifted education</li> </ul>	<ul style="list-style-type: none"> <li>- Experimental, quantitative analysis of effects of instructional strategy on students' achievement scores</li> </ul>
Perspectives on intelligence and giftedness (derived from Fischer et al., 1996)	<p><b>Social Construction Paradigm:</b></p> <p>Intelligence is a socially constructed and changeable consequence of political choices. It is (a) a complex collection of interactive and context-dependent elements, (b) plastic and developing, (c) amenable only to approximate assessment. Cross-cultural similarities in children's reactions to deprivation (e.g. anxiety, resignation) suppress the development of intelligence. 'Giftedness' encompasses the skills, knowledge, and dispositions that are valued or needed in a given society in a given era. Finding diverse talents in diverse settings is preferable to 'sorting' children for giftedness on the basis of a few narrow academic measures.</p>			<p><b>Natural Inequality Paradigm:</b></p> <p>Intelligence is innate and largely immutable. It can be objectively and precisely measured. The 'gifted' can be sorted out based on test scores.</p>

paradigms in gifted education shape the attitudes and beliefs that dominate the field. Undergoing paradigm changes in gifted education is necessary and natural; the field is part of a larger system of education and an aspect of a much larger system of global evolution. Currently, fundamental changes in values and beliefs are influencing the evolution of societies around the globe (Inglehart, 1997). These changes are fueling a major paradigm shift that is altering educators' values and assumptions; shifts such as this are abrupt and disturb the status quo, causing periods of instability and unrest.

There have been several paradigm shifts in the gifted child movement (Cohen, 1998). The traditional paradigm in gifted education was based on assumptions of clearly defined, measurable, culture-transcendent intelligence and the selection and labeling of the gifted (usually through IQ tests) for their inherent abilities.

The second paradigm was derived from special-education emphases on individual educational plans and least restrictive environments based on assessments of students' individual needs. This paradigm ran counter to the one-size-fits-all programming emphasis of the traditional paradigm and was more sensitive to the nuances of individual development, but it was detrimental wherever it over-emphasized students' weaknesses.

Aspects of the as yet ill-defined third paradigm shift seem to include emphases on multidimensional talents (Feldman, 1992; Piirto, 1999; Treffinger & Feldhusen, 1996), multidimensional and context-sensitive conceptions of intelligence (Gardner, 1983, 1993, 1999; Perkins, 1995; Purcell, 1996; Sternberg, 1990, 1993, 1997, 1999b), and awareness of diversity and societal context (Ford, 1996; Ford & Harris, 1999; Frasier, 1995a, 1995b, 1995c; Frasier et al., 1995; Maker, 1996; Peterson, 1999; Piirto, 1999a). If educators of the gifted come to understand the nature of paradigm shifts in the field, they will be able to appreciate the ways in which their work fits into broader educational and societal contexts. In addition, they are more likely to recognize the limitations of earlier paradigms for identifying and serving diverse learners.

### **What Is Theory and Why Is It Important?**

Research appropriately provides much of the direction in any academic field. But by its very nature, most empirical research emphasizes specific pieces of phenomena and cannot adequately address big-picture frameworks. This is especially the case in complex fields. Research in gifted education has not portrayed the whole picture because it tends to address important but small-scale issues in a scattershot approach while phenomena in the field pertain to the most complex system in the universe: the human mind.

Theory can provide big-picture guidance for researchers and practitioners by transcending and connecting the important, but fragmented empirical

findings upon which researchers necessarily focus. Theory is also needed to: (a) account for extant research findings and organize these into a cogent whole, (b) provide research heuristics and suggest new directions for research by highlighting gaps in the knowledge base, (c) provide explanatory frameworks that can help educators discern the special nature and needs that do or do not manifest in gifted and talented children, and (d) clarify the scope and scale of phenomena deemed important to research and practice.

Theories of narrow scope tend to have clarity of detail and strong predictive capacity; theories of broad-scope tend to have strong descriptive and explanatory potential and context-sensitivity. It seems important to embrace both narrow- and broad-scope theoretical perspectives when studying complex phenomena such as the human mind.

The scale of a theory refers to the level of analysis at which it operates; theorists can focus on different levels ranging from macrolevel philosophical frameworks and panoramic, overarching theories, to levels dealing with thought processes and other factors influencing mind development, to practical instructional frameworks and specific learning processes. In order to fully understand the comprehensiveness of conceptual foundations, scholars must appreciate the levels in which their theories fit, and ensure that theorizing in the field addresses all levels (see Cohen & Ambrose, 1993 for more detail about theoretic scope and scale).

### **Competing Views About Methods for Theory Development**

Unfortunately, strengthening conceptual foundations through theoretic awareness is not so simple. While there are varied ways of making philosophical sense of a field, there are also diverse, often conflicting perspectives on theoretic work. Some scholars believe that formal theory usurps too much attention in educational inquiry, and has detrimental effects on practice. For instance, Thomas (1997) claims that theory can be seductive, trapping investigators in preconceived idea frameworks and inhibiting creative solution of educational problems. In a similar vein, Grant and Piechowski (1999) claim that attending to theory development in gifted education may not do much for gifted children, or may even be counter-productive. They claim that formal social-science theory does little good unless that theory is rooted in student-centered, case-based naturalistic inquiry. Without this rooting, much of the theorizing in the field tends to promote morally problematic outside-the-child visions of achievement and productivity as opposed to the inner life and emotional well being of the child.

Others see positive roles for theory in educational investigation. For instance, Ambrose (1996, 1998a) claims that it is necessary to expand and clarify the conceptual foundations that underpin the field in order

to overcome the insularity of our own assumptions about complex phenomena such as creativity and giftedness. Expansion can come from broad searches for relevant formal and implicit theories both within and beyond the field. Clarification can come from careful consideration of the specific contributions each theoretical perspective can make to our understanding of a phenomenon as a whole.

Based on similar assumptions, Sternberg (1990, 1993) develops metaphors of mind that reveal diverse perspectives from which theorists can view intelligence. Sternberg claims that many intelligence theorists mistakenly overgeneralize their theories to the entire phenomenon of intelligence when, in reality, each theory applies to a part of the whole. The metaphorical representations of intelligence make explicit the diverse perspectival differences while collectively enabling more comprehensive visions of mind.

There are proposals to integrate theory in the field; for instance, Cohen (1988, 1992) advocates non-competitive interdisciplinary dialogue and comparisons of diverse theories of giftedness and creativity. Cohen and Ambrose (1993) map out influential theories of intelligence, creativity, and giftedness, categorizing them into theory families according to the tenets of the mechanistic and organismic world views, and highlighting some integrative connections among the diverse theories.

Others point out that complex phenomena of mind require investigation from multiple levels of analysis because theorists, researchers, and practitioners tend to lock into one level while assuming that they have adequate perception of the whole (Ambrose, 1998a; Midgley, 1995, 1998; Wahlsten & Gottlieb, 1997). For instance, Wahlsten and Gottlieb (1997) claim that the intricate systemic interconnections among genetic and environmental influences on intelligence can become visible only if we consider research at multiple levels of analysis including the cultural, societal, anatomical, hormonal, cellular, and genetic, among others.

There are additional reasons for large-scale mapping of theoretic perspectives. For example, Newell (1990) claims that while much impressive 'local' cognitive theory currently provides frameworks for interpretation of small bodies of data in cognitive science, global, integrative, broad-scope theorizing is needed to bring together dissonances and contradictions. It is contradiction that promotes problem-solving and insight in a field.

Sternberg (1999a) uses the dialectical process, advocated by philosopher Georg Hegel, to expose and capitalize on contradictions among diverse philosophical and theoretical camps in cognitive psychology. In the dialectical process, a dominant perspective in a field (the thesis) brings forth an opposing reaction (the antithesis). The dynamic interplay between thesis and antithesis can bring about a productive synthesis of the

two perspectives. From this vantage point, conflicting conceptions of giftedness and talent (e.g. general intelligence vs. multiple intelligences) represent golden opportunities for progress in the field.

Unfortunately, theoretic aspects of education for the gifted and talented are too often ignored by researchers and practitioners. In spite of valid points made by those who caution against the hypnotic effects of formal theory in education (e.g. Grant & Piechowski, 1999; Thomas, 1997), research and practice without theory tends to be banal, superficial, fragmented, and insular. Acknowledging and integrating the necessary and reciprocal relationships of theory, research, and practice can give the field a stronger foundation (Cohen & Ambrose, 1993).

We advocate an eclectic approach to clarification and expansion of theoretical perspectives in gifted education because such an approach is consistent with emerging meta-theoretical insights in other fields and because only through diverse perspectives can we discover the multiple realities of giftedness among diverse groups. These insights imply that large-scale theoretic mapping is necessary because the entirety of any complex phenomenon is simply not visible from a single perspective or a single level of analysis. For instance, in the field of neuroscience, Rose (1998) argues for a more expansive research agenda that would incorporate but go well beyond currently dominant reductive studies of electrochemical processes within individual crania to include socio-cultural shaping influences on mind. At the same time, eclectic does not mean stirring together random bits and pieces, lest we fall into the same traps of fragmented practices. Instead, it is the careful consideration of these various theoretical perspectives and the mapping of the luminous elements within their area(s) of explanation/ vision onto a large frame that differentiates what we advocate from sloppy thinking.

In order to gain a comprehensive grasp of a complex phenomenon, it seems necessary to map as many as possible of the elements of that phenomenon in order to provide big-picture guidance to those who prefer to incisively analyze small subsets of its elements. Interdisciplinary conceptual navigation throughout multiple levels of analysis can promote big-picture appreciation of the intricacies of, and contradictions in, complex phenomena such as intelligence, creativity, and giftedness while preventing scholarly entrenchment and insularity. Expanding our view of a complex phenomenon makes it less likely that theorists and researchers will overgeneralize their own local theories to the whole phenomenon, and less likely that educators will be misled by such overgeneralizations.

### **Influential and Promising Theories Pertaining to Giftedness and Talent**

Gifted education largely rests on theories of intelligence, creativity, and giftedness. In the first edition of

this book, we outlined many of the diverse theories that were influential at that time in gifted education, or that had the potential to influence the field. Due to their number and complexity, these theories are not described again in detail here (see Cohen & Ambrose, 1993 for an extensive overview). Instead, the following outlines some representative recent developments in theories of intelligence, creativity, and giftedness, as well as some potentially informative theories from beyond the field.

*Developments in intelligence theory.* The debate over IQ-based definitions of intelligence continues to rage unabated. The publication of *The Bell Curve* (Herrnstein & Murray, 1994) set off yet another round of altercations between those defending the credibility of the general intelligence factor (e.g. Gottfredson, 1999) and those highlighting the limitations of IQ-based definitions while portraying intelligence as much more multidimensional and context-situated (e.g. Gardner, 1999; Perkins, 1995; Purcell, 1996; Sternberg, 1999b). In the midst of this debate, other related controversies swirl; for instance, recent developments in genetic research are prompting new rounds of nature-nurture debates. Proponents of behavior-genetic theories of intelligence emphasize the role of genetics, and proponents of socialization theories emphasize the importance of socio-cultural influences (see Sternberg & Grigorenko, 1997 for an overview of these theories).

Yet another debate rages among cognitive scientists who argue over the credibility of two artificial-intelligence-based models of cognition (Baumgartner & Payr, 1995). Proponents of the symbolist view of mind (e.g. Newell, 1990; Simon, 1979) portray cognition as the result of linear, primarily logical, symbolic information processing in the brain. Proponents of the connectionist view (e.g. Churchland & Sejnowski, 1992) highlight nonlinear thought by portraying cognition as arising from parallel distributed processing within the brain's intricate neural networks. Both of these viewpoints are based on computer metaphors of mind.

Still other cognitive scientists believe that the computer metaphors ignore strong contextual effects on human thought. For instance, Cicourel (1995) claims that cognition is embedded in, and strongly influenced by, the subtle nuances of interpersonal interaction and cultural belief systems. Lakoff (1993, 1995) demonstrates ways in which metaphorical frameworks from our shared language systems exert subtle yet strong contextual shaping influences on cognition.

There are some other notable developments in intelligence theory. For instance, Gardner (1999) has expanded his theory of multiple intelligences by adding the naturalist (ability to recognize and categorize natural objects) to his seven original intelligences

while proposing the existential (recognition of deep, fundamental questions) as a potential candidate for yet another intelligence.

In recognition of the abstract, somewhat school-bound, decontextualized nature of most intelligence theories, Sternberg (1997) posits practical intelligence as a necessary theoretical perspective. Practical intelligence is the dimension of mind that enables one to artfully navigate the problem-solving requirements of the real world.

*Developments in creativity theory.* Some scholars claim that early research on creativity erroneously portrayed the creative process as dependent on domain-transcending traits, skills, or dispositions and that recent research corrects this misconception. Instead, creativity should be considered domain-specific (e.g. Baer, 1993, 1998). Others (e.g. Cramond, 1994; Plucker, 1998) argue that claims about the domain-specificity of creativity are premature.

Some recent theory blurs the boundaries between creativity, intelligence, and giftedness; for instance, Heller (1995) suggests that creativity and intelligence are complementary components of mind, which in tandem support complex problem solving. Along similar lines, various scholars explore the ways in which critical, convergent, thought processes support divergent, creative thinking (see Runco, 1998).

Much recent theory portrays creativity as emergent from the complex, systemic intermingling of diverse elements. For instance, Feldhusen & Goh (1995) claim that an understanding of creative development requires an integrative view of cognitive processes (e.g. critical thinking, decision making, metacognition), interests, motivation, attitudes, the nature of creative products and performances, and the shaping influences of environment. In a similar argument, Amabile (1995) and Urban (in press) advocate for systemic views of creativity, which encompass the characteristics of the individual and the nature of the environment instead of narrow conceptions of one or the other.

Others highlight the diversity-creativity nexus. For instance, Arnold, Noble & Subotnik (1996) incorporate a wide range of perspectives that reveal the effects of race, class, and other aspects of social/historical context on the manifestation of women's creative potential. Esquivel & Houtz (1998) provide a similar forum for explorations of the ways in which creativity emerges in culturally and linguistically diverse populations.

*Developments in theories of giftedness and talent.* The major recent theoretical shift in the field of gifted education is the growing emphasis on talent development, which highlights multiple talents at multiple levels of development. For instance, Treffinger & Feldhusen (1996) describe "a strong shift away from the limited academic-intellectual orientation of gifted

education toward a recognition of the nature and importance of talents in the arts, vocational domains, and social-interpersonal areas of human activities” (p. 182).

Gagné (1985, 1993) helped catalyze the shift to talent development with a theoretical model portraying talent as emergent from genetically determined gifts that, under the influence of intrapersonal and environmental impacts, develop into more and more specific talents. Feldhusen (1998) uses Gagne’s construct, among others, in his model of talent development. In Feldhusen’s model, the interaction of genetically determined abilities with environmental stimulation produces emerging aptitudes, abilities, and intelligences, which integrate to support the pursuit of career goals.

Piirto (1999a) presents yet another talent development model, which incorporates genetic foundations, emotional-personality elements, a minimum IQ threshold, and environmental influences (home, school, community, culture, chance, and gender). Given these constraints and influences, the individual’s domain-specific talents are selected and developed according to a calling or vocation.

Rea (2000) borrows from motivation theory to create a different theory of talent development. According to Rea, children can become engaged in counterproductive cycling between anxious overexcitement and apathetic boredom, or highly productive cycling between exciting exploration and calm, serious reflection. The latter cycling emerges from interactions among optimal challenge, undivided interest, and optimal arousal.

As in creativity and intelligence theory, most theorists are recognizing that giftedness and talent emerge from the complex interaction of diverse elements; consequently, they are using broad-scope perspectives to incorporate the expansiveness and intricate complexities of mind-related phenomena. For instance, Simonton (1998) uses three disciplinary vantage points (biology, sociology, psychology) to explain differing developmental processes leading from childhood promise to adult achievement. Simonton claims that biological-genetic factors, socio-cultural and economic influences, and specialized expertise and motivation all intertwine to enhance or suppress the development of specific talents.

### **Some Promising Theories from Outside the Field of Gifted Education**

As Piaget (1981) noted, reading around a field mitigates against parochialism and promotes creativity in that field. Consideration of the established theoretical terrain pertaining to giftedness and talent helps clarify conceptual foundations. But a truly eclectic, epistemologically diverse treatment of theoretical perspectives would push back the edges of the map to

explore potentially fruitful theories from disciplines normally thought of as beyond the field. This section includes some examples of outside-the-field theories and constructs that could influence thinking about giftedness and talent; these examples are by no means exhaustive of potentially influential interdisciplinary connections.

*Complexity theory.* The rapidly growing interdisciplinary science of complexity is one body of knowledge with potential implications for conceptions of giftedness and talent. Complexity theory includes broad-based, interdisciplinary searches for patterns of similarity in the structure and dynamics of complex adaptive systems. These systems evolve unpredictably through states of orderly stability and chaotic turbulence, sometimes finding new patterns of order at higher levels of complexity (Axelrod, 1997; Jervis, 1997; Kauffman, 1995). Kelso (1995) and Sterling (1992) promote theories of the brain as a nonlinear dynamic system in which new thought patterns emerge from self-organization. These theories highlight the importance of environmental influence, ambiguity, and unpredictability in creativity.

*Cognitive science.* Some scholars are continuing the recent trend of borrowing insights from cognitive science to expand conceptions of giftedness and talent. For instance, Pelletier & Shore (in press) use comparisons of novices and experts to illuminate the nature of giftedness. They use research findings on flexibility, metacognition, and knowledge organization to clarify processes that promote development from novice levels to expert levels in a domain. Sternberg & Hovarth (1998) also explore the expertise-giftedness nexus, delineating eight different ways in which conceptions of expertise correspond with conceptions of giftedness. These include differential degrees of knowledge accumulation, knowledge organization, automaticity of skills, metacognitive capacity, creative capacity, and practical savvy among others.

*Quantum physics.* Theories of mind based on quantum physics have been operating at the fringes of mind-related fields (Eccles, 1996; Goswami, 1988, 1990, 1995, 1996; Penrose, 1994). These theories detail ways in which the strange paradoxes of the submicroscopic quantum world (e.g. non-local causality) can operate within microstructures of the brain, thereby contradicting traditional eliminative-materialist assumptions that the mind is little more than an epiphenomenon of electrochemical actions within individual crania. If on target, quantum theories of mind eventually could undermine the dominant mechanistic theories of cognitive science. They raise the possibility that underlying, holistic interconnections influence those processes beyond the scope of sensate perception and material causality.

Table 2. Some Recent Developments in Theoretical Perspectives in Gifted Education and some Foreign Theories: Potential Luminous Elements and Potential Problems. © 1999 Don Ambrose.

Theoretical Perspective	Source Discipline(s) and World-View Derivation (The latter is in italics)	Current or Potential Luminous Elements for Understanding Giftedness and Talent and Some Potential Problems with the Perspective
<b>Talent-Development Theories and Models</b> (Feldhusen, 1998; Gagne, 1985, 1993; Piiro, 1999b; Rea, 2000)	Primarily psychology, gifted education <i>organicism, contextualism, and some mechanism</i>	<ul style="list-style-type: none"> <li>- Reveal dynamics conducive to development of diverse talents.</li> <li>- Could 'democratize' gifted education by supporting talent development for all.</li> <li>- Could over-emphasize precocity.</li> </ul>
<b>Multidimensional, Systemic, Context-Situated Theories of Intelligence</b> (Gardner, 1999; Sternberg, 1999b), <b>Creativity</b> (Amabile, 1995; Feldhusen & Goh, 1995; Heller, 1995), and <b>Giftedness</b> (Simonton, 1998)	Primarily psychology <i>organicism, contextualism</i>	<ul style="list-style-type: none"> <li>- Raise awareness that gifts and talents can be diverse and mutually shaping.</li> <li>- Highlight influences of socioeconomic, political, and cultural environment.</li> <li>- Undermine mechanistic-reductionist assumptions.</li> </ul>
<b>Behavioral-Genetic Theories:</b> Specific genes are the basis of cognitive abilities. (Plomin, 1997; Scarr, 1997)	Molecular biology <i>primarily mechanism</i>	<ul style="list-style-type: none"> <li>- May specify heritability factors that underlie variance in some cognitive abilities.</li> <li>- Could obscure influence of context on intelligence.</li> </ul>
<b>Critical and Socialization Theories of Intelligence:</b> Societal context shapes the development of intelligence (Fischer et. al., 1996; Wahlsten & Gottlieb, 1997)	Psychology, sociology <i>contextualism, organicism</i>	<ul style="list-style-type: none"> <li>- Could keep genetic determinists honest at a time when new technology is highlighting genetic discovery.</li> <li>- Could aid in considering attributes and behaviors of giftedness in cultural context.</li> </ul>
<b>Artificial-Intelligence, Computer-Based Models of Cognition</b>	Cognitive science (an interdisciplinary field) <i>mechanism, formism (symbolist) contextualism, formism (connectionist)</i>	<ul style="list-style-type: none"> <li>- Symbolists refine our knowledge of logical cognitive processes.</li> <li>- Connectionists emphasize the importance of unpredictable connection making in creative thought processes.</li> <li>- Both symbolists and connectionists promote the belief that cognition derives from inside-the-head computation.</li> </ul>
<b>Context-Embedded Models of Cognition from Cognitive Science:</b> Culture and language strongly shape and partially structure cognitive processes (Cicourel, 1995; Gillespie, 1992; Lakoff, 1993, 1995)	Sociology, linguistics, and psychology <i>strong contextualism, some formism</i>	<ul style="list-style-type: none"> <li>- Could prevent entrapment within the computer metaphor by showing that cognition is more than inside-the-head computing. Highlight sociocultural influences on giftedness and talent.</li> </ul>
<b>Economic Theories of Creativity:</b> Supply and demand processes influence creative work (Rubenson, in press; Rubenson & Runco, 1992; Sternberg & Lubart, 1993)	Economics, psychology <i>contextualism, some formism</i>	<ul style="list-style-type: none"> <li>- Reveal motivational patterns in creativity.</li> </ul>

Table 2. Continued.

Theoretical Perspective	Source Discipline(s) and World-View Derivation (The latter is in italics)	Current or Potential Luminous Elements for Understanding Giftedness and Talent and Some Potential Problems with the Perspective
<p><b>Creativity Through the Lenses of Gender and Cultural-Linguistic Diversity</b> (Arnold, Noble, &amp; Subotnik, 1996; Esquivel &amp; Houtz, 1998)</p>	<p><i>contextualism</i></p>	<ul style="list-style-type: none"> <li>- Strengthen awareness of environmental opportunity and shaping influences on manifestation of creativity.</li> </ul>
<p><b>Postmodern Theory:</b> rejects mechanistic assumptions such as objectivity and reductionism; Highlights sociocultural and political influences such as effects of power and privilege on 'identification' of the gifted (Piirto, 1999a; Cahoone, 1996)</p>	<p>Interdisciplinary, but primary influence is from philosophy <i>primarily contextualism</i></p>	<ul style="list-style-type: none"> <li>- Challenges basic assumptions (e.g. the giftedness construct, the 'gifted' as a national resource).</li> <li>- Highlights 'gifts' of collaboration and altruism while putting competitive, self-interested individual achievement in better perspective.</li> <li>- Could mitigate greed, conflict, and social stratification in society.</li> <li>- Challenges dominance of positivistic inquiry.</li> </ul>
<p><b>Complexity Theory:</b> Minds, children, classrooms are complex, self-organizing, context-sensitive, unpredictable, chaotic-orderly, dynamic systems (Kelso, 1995; Sterling, 1992)</p>	<p>Originally physics and chemistry, now applied in diverse fields such as biology, economics, and political science <i>primarily contextualism, formism</i></p>	<ul style="list-style-type: none"> <li>- Highlights context-sensitivity and spontaneous cognitive transformations</li> <li>- Undermines prediction and control.</li> </ul>
<p><b>Quantum Theories of Mind:</b> Consciousness is a fundamental aspect of mind with causal influence, not simply an epiphenomenon of electrochemical, cranial processes (Eccles, 1996; Goswami, 1988, 1990, 1995, 1996; Penrose, 1994)</p>	<p>Theoretical physics and neuroscience <i>formism, organicism, contextualism</i></p>	<ul style="list-style-type: none"> <li>- Emphasize intuitive processes of mind.</li> <li>- Raise possibility that cognition has very deep, untapped levels, with holistic, transcendent effects beyond the scope of mechanistic tools and constructs.</li> <li>- Could transcend world views.</li> <li>- Could undermine mechanistic, materialist theories.</li> </ul>

*Economic theories.* Economic concepts have been influencing theories of creativity. For instance, two emerging economic perspectives highlight the motivational aspects of creative activity. The psycho-economic model (Rubenson, in press; Rubenson & Runco, 1992) portrays creative activity as emergent from supply and demand interactions between the individual, the field (which determines market demand for creative activity), and a particular domain (the market itself). According to another economic perspective, the investment theory of creativity (Sternberg & Lubart, 1993), successful creators tend to recognize ideas that are undervalued and invest themselves in these ideas, using aspects of their intelligence, intellectual style, knowledge, personality, motivation, and environmental context to produce creative ideas.

*Philosophical developments.* The often ignored field of philosophy can contribute important perspectives on giftedness, creativity, and intelligence. For instance, postmodern theory is challenging modernist (primarily mechanistic) assumptions in most of the social and behavioral sciences, and the field of gifted education is not immune. Postmodern theorists regard most of the mechanistic tenets of modern scholarship as obsolete, illegitimate, or at least inadequate bases for inquiry (Cahoone, 1996). For instance, They reject assumptions that investigators can achieve objectivity, simplicity, completeness, and certainty, and that the study of human phenomena can be based on or reduced to the methods of the physical sciences. They point out that socio-cultural and political contexts strongly shape the assumptions of scholars, as well as the nature of the phenomena they study.

Piirto (1999a) details some overarching themes from postmodern scholarship, and uses them as critical lenses for analysis of education of the gifted and talented. For instance, the theme of constitutive otherness highlights the ways in which commonly accepted constructs such as giftedness are maintained through exclusion of those labelled nongifted. Exclusion obscures the 'gifts' of women, minorities and others while highlighting the abilities of those whose gifts more closely match modernist (i.e. mechanistic) values.

*Critical theory.* While not purporting a theory per se, Fischer et al. (1996) report compelling evidence from sociological theory and research that encourages second thoughts about traditional theories of intelligence and giftedness. They show how systems of socio-economic stratification around the world depress the opportunities and initiative of underprivileged racial and ethnic groups. Deprivation, segregation, and stigmatization of lower-caste groups in many nations produce consistent patterns of anxiety, fatalism, and resignation in underprivileged children. These patterns, combined with inequality of educational opportunity,

undermine intelligence test scores and academic achievement. Of most pertinence to conceptions of giftedness, patterns of low intelligence and achievement scores persist in populations that were initially captured or conquered by ancestors of the dominant culture because these populations face long-term stigmatization. In contrast, low intelligence and achievement scores rise to levels comparable with the dominant populations within a few generations in immigrant groups for whom socio-economic deprivation is temporary. Fischer et al. (1996) claim that race or genetics cannot explain the dramatic intergenerational rebound in intelligence among the immigrant groups, but dramatic changes in socio-economic status can explain it. These patterns highlight the importance of societal power-control structures in showcasing the abilities of some children while suppressing those of others.

In general, these theories and perspectives from beyond the field raise some new possibilities for conceptions of intelligence, creativity, and giftedness; they also raise some issues about research methods, philosophical assumptions, and political issues in the field.

#### **Clarifying and Expanding Conceptual Foundations Through Luminous Elements of Theory**

It is important to scrutinize new theoretical developments in the field and interesting theories from beyond the field for their philosophical bases and biases, and for their potential impact on gifted education. In terms of philosophical bias, if we analyze new theoretical developments for their consistency with the tenets of the four root-metaphorical world views and discover that most or all of them are rooted in one world view, we can surmise that new theory suffers from entrapment within a single perspective, or that it is compensating for a prior world-view imbalance. If, on the other hand, some new theories are consistent with one world view, while others are consistent with another, we can assume that new thinking in and outside of the field makes room for diverse perspectives. If so, there is more hope for comprehensiveness and structural corroboration in our emerging understanding of giftedness and talent and more opportunity to embrace both diverse conceptions of giftedness and diverse gifted and/or talented learners.

In terms of potential impact on the field, wide-ranging considerations of diverse theories can tease out luminous elements that stretch our thinking about intelligence, creativity, or giftedness. Cohen (1992) calls the strengths of a given theory its 'luminous elements', as they have an aesthetic rightness and light-shedding quality that resonates with knowledgeable theorists, researchers, or practitioners. In recognition that no single theory captures all important aspects of mind (Ambrose, 1998a; Newell, 1990; Rose, 1998;

Sternberg, 1990, 1993, 1999a; Wahlsten & Gottlieb, 1997) it can be helpful to carry out an active search for luminous elements of theory from diverse interdisciplinary sources with relevance to intelligence, creativity, and giftedness: a search such as the rudimentary example in the previous section.

The beauty, truthfulness, and relevance of these luminous elements enables them to reveal the depths, nuances, and the importance of specific phenomena. Such revelations can provide important keys to understanding the entirety of a complex phenomenon such as optimal mind development. They can help reveal gaps in the knowledge base and establish connections among diverse theoretical perspectives while keeping important aspects of mind development at the forefront of our attention.

Table 2 is an embryonic example of a search for luminous elements in recent theory, and in theories beyond the field. The overview highlights some emerging conceptual conflicts and possibilities for syntheses. It also details the current or potential impact of each perspective on conceptions of giftedness and talent and possible problems from these perspectives.

Theorists, researchers, or practitioners exposed to diverse theoretical luminous elements such as those outlined in Table 2 have the opportunity to expand their conceptions of giftedness and talent while preventing implicit entrapment within any single perspective. Consistent with advice to employ more than one world-view perspective when analyzing complex phenomena (Ambrose, 1996, 1998a; Gillespie, 1992; Overton, 1984; Pepper, 1942), Table 2 enables considerations of giftedness and talent from all four world-view perspectives. Also, consistent with advice to consider complex phenomena from multiple levels of analysis (Ambrose, 1998a; Midgley, 1995, 1998; Wahlsten & Gottlieb, 1997), Table 2 enables conceptions of giftedness and talent from the microlevels of molecular biology and neuroscience to the macrolevels of sociology, economics, and political science. It is the macroperspectives that reveal the subtle influences of socio-economic and political contexts, thereby revealing the conceptual blind spots that obscure the gifts and talents of minority populations. In addition, conflicting viewpoints in the table (e.g. behavioral-genetic vs. socialization theories of intelligence) create opportunities for attempts at dialectical syntheses such as those advocated by Sternberg (1999a).

We advocate for a largely philosophical meta-discourse in and around the field: a dialogue with the purpose of discerning emerging new big-picture patterns, and how these augment, extend, or work against the old. It should be a search for new connections and new possibilities.

We agree with the critics of theory who warn against blind acceptance of ideologically saturated social-science theories as tools for prediction and control of human phenomena (e.g. Thomas, 1997; Grant &

Piechowski, 1999). Instead, diverse theories should be used collectively as potentially useful clues that can guide our investigations of the many facets of human potential. A consideration of a wide range of diverse theories and philosophical perspectives can provide new perceptions of varied dimensions of giftedness and talent in diverse populations.

# Theory and Research on Curriculum Development for the Gifted

Joyce VanTassel-Baska<sup>1</sup>

## Introduction

How can educators help a gifted student to excel? The answer to this question is a complicated one because much of our research on what impacts the lives of gifted individuals relates more to the role of parents (Feldman, 1985; Bloom, 1985), the role of internal factors such as motivation (VanTassel-Baska & Olszewski-Kubilius, 1989; Csikszentmihalyi, Rathunde & Whalen, 1993), the role of crystallizing experiences (Gardner, 1985), the role of conative factors such as will and passion (Snow, 1994), or the role of chance (Tannenbaum, 1983).

Yet what happens to a child in school should have a significant positive effect on the processes of learning. Gifted and talented students, like all students, have the right to a continuity of educational experience that meets their present and future academic needs. When an organized, thoughtful curriculum plan is in place and when that curriculum is supported by an articulate, informed educational leadership, the probability of capturing the interest and energy of our ablest young thinkers is markedly enhanced. Certainly an organized and appropriate curriculum is a key ingredient in this complex blending of circumstance so central to the transformation of a gifted learner's initial capacity for intellectual activity into a mature competence for academic and professional accomplishment.

Key beliefs and assumptions have guided the thinking of most curriculum theory in gifted education (Passow, 1982; Gallagher, 1985; Maker & Nielson, 1996; VanTassel-Baska, 1998). These beliefs may be stated succinctly as follows:

- (1) All learners should be provided curriculum opportunities that allow them to attain optimum levels of learning.
- (2) Gifted learners have different learning needs compared with typical learners. Therefore, curriculum

must be adapted or designed to accommodate these needs.

- (3) The needs of gifted learners cut across cognitive, affective, social, and aesthetic areas of curriculum experiences.
- (4) Gifted learners are best served by a confluent approach that allows for accelerated and advanced learning, and enriched and extended experiences.
- (5) Curriculum experiences for gifted learners need to be carefully planned, written down, and implemented in order to maximize potential effect.
- (6) Curriculum development for gifted learners is an ongoing process that uses evaluation as a central tool for future planning and revision of curriculum documents.

Over twenty years ago, national reports in the United States ushered in a new era for educational and curricular change, predominantly in science and mathematics. Today, educators are still faced with a barrage of reports that describe deficiencies in the current instruction in mathematics and science and in other content disciplines as well. *A Nation at Risk* (National Commission on Excellence in Education, 1983) reported on the abysmal failure of public education in exposing students to full secondary programs in science and mathematics. The Carnegie Report (1986) further documented the need for more advanced course taking in these subjects by larger numbers of the secondary school population. The College Board's *Project Equality* (1983) outlined maximum competency skills in academic areas that require mastery in today's technologically advanced world. The most stringent recommendations on curriculum were reported by the National Science Commission (1983) which prescribed four full years of science and mathematics for the majority of students in American schools.

In the early 1990s, the American reform movement had taken on global significance; all countries focused on the importance of education. All countries see their future economic hopes linked to an educated citizenry,

<sup>1</sup> College of William and Mary, Williamsburg, Virginia, USA.  
E-mail: jlvant@facstaff.wm.edu

skilled in the world technologies. Moreover, the demographic make-up of many developed countries is pluralistic, thus instantly globalizing the issues. The results of the Third International Math and Science Study (National Center for Education Statistics, 1997) attest to the sense of importance attached to student performance at elementary and secondary levels worldwide.

Based on the proliferation of reports on problems and remedies, it is clear that education has and is experiencing significant pressure for reform and curricular change. In particular, there is a strong interest in focusing efforts on raising the level of performance for all learners and a belief that the successful approaches to the achievements of the gifted can also enhance the educational enterprise for those who are less able.

Although many local school efforts have not been responsive to the perceived needs of a modern technological society, curriculum for the gifted and talented provides a starting point to upgrade these efforts, particularly in areas that reports have cited as most deficient: mathematics, science, technology, and foreign language. Yet practitioners of theoretical ideas about curriculum for the gifted must be sensitive to the organizational structure of the schools, contemporary K-12 curriculum needs, and the recommendations for change being advocated by these major studies.

### **The Forces That Drive Curriculum**

Based on the calls for reform at steady rates over the last decade, one would expect a commensurate interest in curriculum development projects. Yet very few large-scale curriculum projects have been funded since the splurge of the 1960s. However, curriculum development in math and science is now in the forefront of educational reform. Examples include the Amoco Foundation's \$50 million grant to the University of Chicago to change the shape of American mathematics education at the elementary and secondary levels, new NSF-funded projects in science and mathematics with a heavy focus on technological application, and AAAS science projects that capitalize on new science concepts. Within gifted education, major curriculum development projects have been funded by the United States Department of Education under the Javits Gifted and Talented Act. These projects presage a renewed interest in serious curriculum work for gifted learners.

What has caused this resurgence of interest in curriculum? One of the social forces at work is our concern as a nation for meeting future workforce needs. Wirsup (1986) reported on the dismal status of America's students in math and science when compared to their Russian, Japanese, and West German counterparts. Numerous reports over the last few years continue to document similar deficiencies in performance (Darling-Hammond, 1990; Stevenson & Stigler, 1992). At the national level there has been a pronounced shift in focus from issues like discipline and

community involvement to hard questions about the content and sequence of curriculum. The egalitarian philosophy that dominated the last twenty years of educational policy altered curriculum standards, reduced requirements, and created an elective system that spawned low test scores and gaps in traditional knowledge. A concomitant focus on the education of the disabled sparked an examination of our educational priorities. The billions of dollars allocated to tailoring educational programs to the special needs of disabled children as a result of the passage of PL 94-142 raised consciousness about the cost of responding to individual needs of learners at appropriate levels. The current concerns about changing demographics, work force, competency issues, and negative international education comparisons further exacerbate the need for reform.

Juxtaposed with these social, political, and economic forces within educational systems is new research that affects thinking about the nature of curriculum change desired. New studies about intelligence (Gardner, 1983; Sternberg, 1985) and how children learn are available to shape the curriculum process.

While limited research has been conducted on curriculum for the gifted *per se*, current research in teaching and learning appears important to our conceptual framework for understanding appropriate curriculum for the gifted. For example, curriculum planners for the gifted have long advocated the optimal match between learner capacity and level of experiences provided; new evidence for this principle has emerged from studies of human development where it was found that when both personal skill level and challenge level are correspondingly high, adolescents experience a state of 'flow' which allows for optimal learning (Csikszentmihalyi, 1990).

Current learning research is also deeply rooted in the basic disciplines of reading, writing, mathematics, and science. Much on-going research is attempting to explain how children master complex knowledge structures and procedures (Brown & Campione, 1986). In both reading and mathematics, current research has supported a meaning-based approach that provides appropriate drill and practice in key activities (Resnick, 1984; Anderson, Herbert, Scott & Wilkinson, 1985).

Studies of thinking also contribute to understanding curriculum directions for the gifted. Expert-novice comparisons in various fields (Sommers, 1980; Berliner, 1985) have yielded differences favoring experts in metacognitive acts like planning and revising. A collection of research on expertise has revealed that the successful utilization of these skills may be content-specific. Rabinowitz & Glaser (1985) found that expert performance entailed a large knowledge base of domain-specific patterns, rapid recognition of situations in which these patterns apply, and the use of forward reasoning based on pattern manipulation to reach solutions. Ericsson & Lehman (1996) in studies

of athletes and chess masters assert that domain specific expert behavior emerges out of a triad of experience, instruction, and practice.

Further support for such domain-specific research comes out of studies which use general content-independent cognitive strategies and which find no clear benefits outside the specific domains in which they are taught (Pressley, Snyder & Carigha-Bull, 1987). Thus, research on transfer suggests that "thinking at its most effective [level] depends on specific context-bound skills and units of knowledge that have little application to other domains" (Perkins & Saloman, 1989, p. 119).

Curriculum is also being affected by larger social and political contexts. Computer technology has found its way into the curriculum as a 'basic' subject rather than as a peripheral. Global interdependence has become a major organizational theme of special programs in all content areas, not just social studies. On the other side of the ledger, moral majority advocates have brought about the dissolution of values education, and other educational foci that encouraged free and open inquiry by students.

A number of years ago, Goodlad (1979) posited that curriculum decision-making is done at two levels, each in isolation from the other. School boards effect curriculum policy, and teachers implement classroom curriculum. Little curriculum leadership is provided at a middle level by building principals or central office staff. Consequently, curriculum implementation as a standardized process does not occur in most public school settings. Even skeptical parents are not likely to challenge teachers in an area heavily loaded with issues of expertise and academic freedom.

But curriculum is still mostly driven by the inertia of the status quo, a system of skill-based areas of inquiry that proceeds on a continuum from first grade to twelfth grade, buttressed by basal texts and little examination of the 'why' of a curriculum offering at a particular point in the sequence. For example, algebra was not in the school curriculum sixty years ago, and now the debate rages as to its appropriateness at the ninth-grade level where it was initiated and has tended to stay. Reading continues to follow a similar illogical path of development based on a curriculum model that ignores individual readiness issues.

Since curriculum is at a point of potential change, the opportunity for educators of the gifted to take a strong role in defining what it should be for the most able, the process by which it is formulated, and the diversity of products or outcomes to be anticipated is at hand. It is through appropriate curriculum design and delivery for the top five per cent of the population that the whole of curriculum can be upgraded and enhanced. The curricular work for the gifted can spearhead higher standards and more rigorous methodologies in addressing the needs of the rest of the student body.

### *A Curriculum Philosophy for the Gifted*

Eisner & Vallance (1974) presented five conceptions of curriculum that have shaped the thinking of many educators, and represent strong philosophical orientations for what a view of curriculum for the gifted might be. Moreover, educators of the gifted have influenced curriculum philosophy through both the venue of new conceptions of intelligence (Sternberg & Davidson, 1986; Gardner, 1991) but also through new ways of thinking about nurturing our best learners in schools (Gagne, 1995; Piirto, 1999).

1. *Curriculum as the development of cognitive process.* This orientation in the education of the gifted has focused on process skill development and has led to the adoption of curriculum materials organized around higher level thinking skills. Having its roots in cognitive psychology, it has fostered an information-processing model of curriculum that uses cognitive and meta-cognitive skills as the centerpiece of all learning activities. Implicit in this view is the assumption that learning cognitive skills will translate across, apply to, and enhance any field of inquiry a student may encounter. Many programs for the gifted, which reflect this orientation, have emphasized critical thinking, creative thinking, and problem solving as the substance of their curricula, treating these process skills as content dimensions in their own right. Research would support this orientation if there are also ample opportunities for applying cognitive skills directly to content (Perkins & Saloman, 1989; Sternberg, Torff & Grigorenko, 1998a).

2. *Curriculum as technology.* This approach to curriculum is also process-oriented, but focuses on the organization of curriculum into student inputs and outputs. This view of curriculum relies heavily on stated behavioral or performance objectives with measurable outcomes that can be tested in order to determine educational progress or achievement. Learner outcomes developed in individual states and by several national groups attest to the current centrality of this curriculum orientation. It assumes that curriculum standards must be explicit, taught to, and tested for. This view of curriculum sees curricular effectiveness and efficiency realizable if a learning system is adopted by schools rather than piecemeal changes (Spady & Marshall, 1991; O'Day & Smith, 1993). Clearly this view of curriculum dominates the work of the reform movement calling for systemic changes at all levels of existing educational systems (Fuhrman, 1993).

3. *Curriculum as personal relevance.* This orientation promotes a child-centered model that values curriculum experiences which are tailored to individual student needs. The interest of students in specific areas guides the curriculum. The goal of such curriculum is to be personally engaging and to offer consummatory

experiences that will provide growth at each student's level of understanding. Several curriculum models in gifted education employ this orientation. Renzulli & Reis (1994), Moon & Feldhusen (1994), and Betts (1991), favor this orientation because of its emphasis on self-directed learning. Gifted students become responsible for their own curriculum through contracts with a facilitator who assesses interest and ability. The interaction of student and facilitator in mutually agreed upon work form the central core of curriculum experiences.

*4. Curriculum as social reconstruction.* This view of curriculum holds that the purpose of educational institutions is to be an agent for social change and that the content of curriculum should be viewed within the larger social and cultural realm. Banks (1999) has identified four levels of a curriculum that moves toward social action. At the first level, students encounter specific material related to diverse cultures; at a second level they encounter an understanding of the contributions of various cultures; at a third level they transform their understanding based on exposure to multiple perspectives and viewpoints of diverse cultures. At this level, key concepts like discrimination, tolerance and social justice become a central focus. At the fourth level, social action occurs. Engaging students in social action such as drafting a piece of legislation, taking a poll of neighborhood opinions regarding nuclear energy, or organizing a school anti-pollution campaign typify the curricular experience as part of social reform. Most multicultural trends in curriculum have their philosophic roots in this orientation (Hernandez, 1989; Ford-Harris, 1996).

*5. Curriculum as academic rationalism.* This curriculum orientation has its roots in the Western tradition of rational humanism. Specifically, it adheres to an ideal of education as a way of providing students with an understanding of great ideas and an ability to analyze and synthesize past achievements. It recognizes a core of work as central to our evolution as a culture (Hirsch, 1989). It further espouses a belief in the structure of knowledge as embodied in the organization of academic and artistic fields of inquiry, and seeks to instruct students within those content disciplines. Most of the 'durable' curriculum that is used in gifted programs flows from this general orientation. Both Advanced Placement (AP) and International Baccalaureate (IB) curriculum focus on this view. This philosophy is heavily oriented toward a discipline- or content-based approach to learning and organizes experiences accordingly. In many respects the multiple intelligences view of curriculum is also grounded in this philosophical orientation (Gardner, 1995).

Although educators are free to choose among these curriculum philosophies, the most effective curricula incorporate all of them to some extent. Yet the

academic rationalist's view most closely accommodates the current curricular organization of schools, and has guided most long-term curriculum efforts. The major challenge to the traditional view in gifted child education has come from those models favoring individual student-centered approaches to curriculum (e.g. the School-wide Enrichment Model, and the Autonomous Learner Model). This viewpoint has impacted greatly the thinking of gifted child education worldwide.

#### *Research on Curriculum Models*

The history of curriculum development for the gifted has been fraught with problems just as the general history of curriculum development in this country has been. The curriculum enterprise in general has suffered from neglect since the Sputnik craze in the 1960s. Only with the new national standards movement have we seen a renewed interest in the issue of curriculum. Such contemporary interest, however, has also spawned additional concerns about differentiating for gifted learners rather than raising the standards for all learners. Negotiating between the need to respond to advanced learners as a group and the need to provide high level equitable access to all learners creates an interesting challenge for gifted educators.

The most successful curriculum models for gifted learners have been developed based on acceleration principles for advanced secondary students (VanTassel-Baska, 1998). The International Baccalaureate program and the College Board Advanced Placement Program are perceived by many American school districts to represent the highest levels of academic attainment possible for secondary students and are thought to provide important stepping stones to successful college work. Thus one approach to curriculum development for the gifted may be seen as a 'design down' model where all curriculum at K-12 is organized to promote readiness for college and the process is both speeded up and shortened along the way for the most apt.

Alternatives to this viewpoint abound, however, and tend to focus on learning beyond or in lieu of traditional academics. Most of the curriculum models cited in this chapter ascribe to an enriched view of curriculum development for the gifted, one that addresses a broader conception of giftedness, taking into account principles of creativity, motivation, and independence as crucial constructs to the development of high ability (Renzulli, 1986; Maker & Nielson, 1995). These enrichment views also tend to see process skills such as critical thinking and creative problem solving as central to the learning enterprise, with content choices being more incidental. Evidence of student work through high quality products and performances is also typically highly valued in these models.

Most of the enrichment-oriented approaches to curriculum development for the gifted emanated from

the early work of Leta Stetter Hollingworth, and her curriculum template for New York City self-contained classes. Strongly influenced by Deweyan progressivism, she organized curriculum units that allowed students to discover connections about how the world worked, to discover the role of creative people in societal progress by having students study biography, and promoting the role of group learning through discussion and conversation about ideas (Hollingworth, 1926). In some respects, contemporary curriculum development efforts have not surpassed her early work in scope, purpose, and delivery.

Accelerative approaches to learning owe much to the work of Terman & Oden (1947), Pressey (1949), and early developers of rapid learning classes which enabled bright students to progress at their own rate. Early educational examples of auto-didacticism and tutorials also encouraged a view of learning that promoted independent interest and a self-modulated pace (VanTassel-Baska, 1995). Thus current curriculum models are grounded in a history of research, development, and implementation of both accelerative and enrichment approaches, typically implemented in self-contained classes since the level of content instruction could be modified based on the group. Chief differentiation approaches early in the history of this field then lay in attention to differences between gifted and non-gifted populations. One might argue that today's views of differentiation tend to center far more on individual differences among the gifted in respect to aptitudes, predispositions, styles, and experiences (Gardner, 1995; Benbow & Stanley 1996; Lubinski, 1996; Snow, 1989) than on the group difference paradigm, for both curriculum employed in and out of school.

### *Analysis of curriculum models*

As curriculum has become more a centerpiece of program activity for the gifted, the field has deepened its connections to key criteria that constitute a viable curriculum model. Curriculum models have to provide a system for developing and designing appropriate curriculum for a target population. As such they have to identify elements of design and show how they interact in a curriculum product; a model has to be utilitarian in that it can be easily applied to all major areas of school-based learning. A model also has to be flexible in respect to age groups to which it would apply; the central elements need to work for kindergarten age gifted children as well as high school students. A curriculum model must also have relevance in multiple locations and learning settings; it would need to work in tutorials as well as large classes. Finally, curriculum models for the gifted have to differentiate the particular needs of this population for curriculum and instruction.

Each of the models discussed in the following section meet these criteria. The two most researched

models and best known are described first, the talent search model and the School-wide Enrichment Model (SEM), because both have defined the major curriculum efforts of the gifted education field since the middle 1970s and both also represent well the persistent programmatic division in the field between accelerative and enrichment approaches. Moreover, each of these models has over a decade of research, development, and implementation behind it; none of the other models described have enjoyed such longevity, widespread use, or research attention.

### *The Talent Search Model of Talent Identification and Development*

The overall purpose of the talent search model is to educate for individual development over the lifespan (Benbow & Stanley, 1983; Benbow, 1986; Stanley, 1991). Major principles of the model include: (1) use of a secure and difficult testing instrument that taps into high level verbal and mathematical reasoning to identify students, (2) a diagnostic testing – prescriptive instructional approach (DT-PI) in teaching gifted students through special classes allowing for appropriate level challenge in instruction, (3) use of subject matter acceleration and fast-paced classes in core academic areas, as well as advocacy for various other forms of acceleration, and (4) curriculum flexibility in all schooling (Daurio, 1978; Stanley & Benbow, 1983). The model has been developed at key university sites across the country with some adoptions by local school districts who have established fast-paced classes.

The Study of Mathematically Precocious Youth (SMPY) officially started in September of 1971 at Johns Hopkins University (JHU) and is now being continued, since 1986, at Iowa State University. From 1972 through 1979, SMPY pioneered the concept of searching for youth who reason exceptionally well mathematically (i.e. a talent search) (George, 1976; Stanley, 1976, 1977, 1978). In 1980, the talent search was extended to verbally gifted youth by others at JHU. For the students identified by the talent searchers, SMPY provided educational facilitation by utilizing acceleration or curricular flexibility and by developing fast-paced academic programs. Gifted students in 7th and 8th grade can participate in these talent searches by taking the College Board's Scholastic Aptitude Test (SAT) or the ACT; almost 150,000 gifted students do so every year. Residential and commuter academic programs in several disciplines are also offered by these centers and other universities and organizations to qualified students.

The research work of SMPY has been strong over the past 27 years, with more than 300 published articles, chapters, and books about the model. Findings of these studies have consistently focused on the benefits of acceleration for continued advanced work in an area by precocious students (Stanley, Keating & Fox, 1974; Kolitch & Brody, 1992), a clear rationale

for the use of acceleration in intellectual development (Keating, 1976), and the long-term positive repeated impacts of accelerative opportunities (Benbow & Arjmand, 1990; Hendricks, 1997). Case study research has also been undertaken to demonstrate how these processes affect individual students (Brody & Stanley, 1991; Benbow & Lubinski, 1994). Other studies have focused more specifically on student gains from fast-paced classes (VanTassel-Baska, 1982; Lynch, 1992). The use of the model has been extensive across all of the United States and in selected foreign countries. Curriculum materials have been developed by talent search staff at various sites and by individual teachers in the summer and academic year programs. Especially noteworthy are the curriculum guides for teaching Advanced Placement courses developed at the TIP program at Duke University. Strong use of articulated course materials are employed on the way to Advanced Placement coursework and testing in mathematics, science, and the verbal areas including foreign language. These materials have been reviewed by practicing professionals and content specialists.

Over the entire 27 years of operation, the model has been very well received by parents and students who constitute the major client groups; schools have been less receptive based on their conservative attitude toward accelerative practices and the emphasis on highly gifted students in subject areas (Lynch, 1990; Benbow & Lubinski, 1996; Benbow & Stanley, 1996).

The model does not have a formal training component, although selection of teachers is a rigorous process carried out carefully in each university and school setting. Content expertise and work with highly gifted secondary students are primary considerations for selection; the model is easy to understand but difficult to implement in schools based on prevailing philosophies. The application of the model that has been most successful is in after school and summer settings in which students complete the equivalent of high school honors classes in three weeks (Benbow & Stanley, 1996).

The SMPY model has proven to be highly sustainable, exhibiting strong replication capacity. Even where countries do not conduct talent searches, students from those countries routinely attend summer programs at talent search universities.

Because the model is content-based, it aligns well with national standards although some of the enrichment emphasis of the standards would be overlooked in implementation. SMPY represents core curriculum on an accelerated and streamlined level. The model is not totally comprehensive in that it addresses students in grades 3–12 who reason exceptionally well mathematically and verbally (Lupkowski & Assouline, 1993; Stanley, 1993). Some studies on spatially gifted students at those levels have also been conducted; curriculum areas are comprehensive, including all of the 33 Advanced Placement course strands. Scope and

sequence work has been articulated for grades 7–12 in some areas of learning. Northwestern University has developed a guide for educational options for grades 5–12.

Longitudinal data, collected over the past 20 years on 300 highly gifted students, have demonstrated the viability of the Stanley model in respect to the benefits of accelerative study, early identification of a strong talent area and the need for assistance in educational decision-making (Swiatek & Benbow, 1991a; 1991b; Swiatek, 1993; Lubinski & Benbow, 1994). A fifty year follow-up study (1972–2022) is in progress at Iowa State University with 6000 students in the sample (Lubinski & Benbow, 1994). This study already rivals Terman's longitudinal study in respect to its longevity and exceeds it in regard to understanding the talent development process at work.

#### *The Schoolwide Enrichment Model (SEM)*

The Schoolwide Enrichment Model (SEM) evolved after 15 years of research and field testing by both educators and researchers (Renzulli, 1988). It combined the previously developed Enrichment Triad Model (Renzulli, 1977) with a more flexible approach to identifying high-potential students called the Revolving Door Identification Model (Renzulli, Reis & Smith, 1981). This combination of services was initially field tested in 11 school districts of various types (rural, suburban, and urban) and sizes. The field tests resulted in the development of the SEM (Renzulli & Reis, 1985), which has been widely adopted.

In the SEM, a talent pool of 15%–20% of above-average ability/high-potential students is identified through a variety of measures, including achievement tests, teacher nominations, assessment of potential for creativity and task commitment, as well as alternative pathways of entrance (self-nomination, parent nomination, etc.). High achievement test and IQ scores automatically include a student in the talent pool, enabling those students who are underachieving in their academic school work to be included.

Once students are identified for the talent pool, they are eligible for several kinds of services. First, interest and learning styles assessments are used with talent pool students; second, curriculum compacting is provided to all eligible students; that is, the regular curriculum is modified by eliminating portions of previously mastered content and alternative work substituted; third, the Enrichment Triad Model offers three types of enrichment experiences. Types I, II, and III Enrichment are usually more appropriate for students with higher levels of ability, interest, and task commitment.

Type I Enrichment consists of general exploratory experiences such as guest speakers, field trips, demonstrations, interest centers, and the use of audiovisual materials designed to expose students to new and exciting topics, ideas, and fields of knowledge not

ordinarily covered in the regular curriculum. Type II Enrichment includes instructional methods and materials purposefully designed to promote the development of thinking, feeling, research, communication, and methodological processes. Type III Enrichment, the most advanced level of the model, is defined as investigative activities and artistic productions in which the learner assumes the role of a first-hand inquirer: thinking, feeling, and acting like a practicing professional, with involvement pursued at as advanced a professional level as possible, given the student's level of development and age.

One comparative study (Heal, 1989) was completed comparing the effects of SEM to other enrichment models or strategies. Other studies report results using within-model comparisons (Delisle, 1981; Reis, 1981) or the SEM program as compared to no intervention (Karafelis, 1986; Starko, 1986). Because control or comparison groups of students participating in alternate or comparison models were not used, it is difficult to attribute various results to participation in the SEM.

Evaluation studies have been conducted in 29 school districts on the perceptions of the model with parents, teachers, and administrators (Reis, 1981; Cooper, 1983; Olenchak & Renzulli, 1989). Positive change in teacher attitudes toward the work as documented.

Delcourt (1988) investigated characteristics related to creative/productive behavior in 18 high school students who consistently engaged in first-hand research on self-selected topics within or outside school. Burns (1988) and Starko (1986) also examined the effects of the Schoolwide Enrichment Model on student creative productivity. Results indicated that students who became involved in independent study projects in the SEM more often initiated their own creative products both *in and outside school* than did students in the comparison group and that multiple creative products were linked to self-efficacy (Schack, Starko & Burns, 1991; Baum, Renzulli & Hebert, 1995).

Several studies have examined the use of the model with underserved populations. Emerick (1988) investigated underachievement of high-potential students. Baum (1985, 1988) and Olenchak (1991) examined highly able students with learning disabilities, identifying both characteristics and programmatic needs. Findings suggest positive effects of the model with these populations.

Compacting studies have sought to document the fact that gifted students are capable of rapidly progressing through regular school curriculum in order to spend time on Type III project work. Results demonstrate knowledge scores as high or higher on in-grade standardized tests than non-compacted peers (Reis & Purcell, 1993).

Two SEM longitudinal studies have been conducted with 18 and nine students respectively. These studies showed that students in the sample maintained similar

or identical career goals from their plans in high school, remained in major fields of study in colleges, and were satisfied in current project work. Moreover, the Type III process appeared to serve as important training for later productivity (Delcourt, 1993, 1994; Hebert, 1993).

The SEM is widely used in schools nationally and internationally in some form; summer training on the model is available at the University of Connecticut, reportedly training 600+ educators annually. The model is perceived by the developer to be closely linked to core curriculum, offers a scope and sequence within Type II activities, and has the potential to be aligned with national standards (Renzulli & Reis, 1994). Teachers are especially enthusiastic about the model as are selected students.

### *The Autonomous Learner Model*

The autonomous learner model for the gifted and talented was developed to meet the diverse cognitive, emotional and social needs of gifted and talented students in grades K-12 (Betts & Knapp, 1980). As the needs of gifted and talented students are met, gifted students will develop into autonomous learners responsible for the development, implementation and evaluation of their own learning. The model is divided into five major dimensions: (1) Orientation, (2) Individual Development, (3) Enrichment Activities, (4) Seminars and (5) In-Depth Study.

One of the criteria used for assessing the appropriateness of a curriculum model is the evidence of research to support its use with gifted and talented learners. To date, no research evidence of effectiveness has been shown with regard to this model's student learning impact, or longitudinal effectiveness with gifted learners. However, six curriculum units and curriculum guides have been produced as a result of dissemination of its ideas. One article reviewed and described the model by presenting guidelines for developing a process-based scope and sequence as well as independent study programs for gifted learners (Betts & Neihart, 1986).

Regardless of the paucity of data on this model, it is one of the most widely recognized and used in the United States (Betts, 1986); teachers have commented positively on its implementation; the model has also been employed at selected sites in other countries. Formal teacher training occurs in three- and five-day segments annually; in its design, a three-year timeline is suggested for model implementation. It does contain a degree of comprehensiveness in that the model applies broadly to all curriculum domains and ages of learners; however, it does not incorporate any features of accelerated learning, thereby limiting one aspect of its comprehensiveness.

### *The Multiple Intelligences Model*

Multiple intelligences (MI) as a curriculum approach was built on a multidimensional concept of intelligence (Gardner, 1983). Seven areas of intelligence were defined in the original published work in 1983, with an eighth intelligence added by Gardner in 1995. They are (1) Verbal/linguistic, (2) Logical/mathematical, (3) Visual/spatial, (4) Musical/rhythmic (5) Bodily/kinesesthetic, (6) Interpersonal, (7) Intrapersonal, and (8) Naturalistic.

Evidence of research based on multiple intelligences translated into practice has recently been documented (Rosnow, Skleder, Jaeger & Rind, 1994; Strahan, Summey & Banks, 1996; Latham, 1997). Most of the research, however, lacks control groups, and therefore generalizations about the model are difficult to infer (Latham, 1997). Longitudinal evidence of effectiveness with gifted students over at least three years has not been documented, although some research has been conducted on incorporating multiple intelligences with other forms of curriculum models (Maker, Nielson & Rogers, 1994).

The Multiple Intelligences Model has been used in the formation of new schools, to identify individual differences, for curriculum planning and development, and as a way to assess instructional strategies (Gardner & Hatch, 1990; Fasko, 1992). A plethora of curriculum materials have been produced and marketed based upon Multiple Intelligences (MI). It holds widespread appeal for many educators because it can be adapted for any learner, subject domain or grade level. The model is not easy to implement and does require teacher training, financial resources and time. Best known project sites for the model are the Key School in Indianapolis, Indiana and the Atlas Project in New York City. While the model has been readily adapted to curriculum, it remains primarily a conception of intelligence applied broadly to school settings as a way to promote talent development for all learners.

Developer concerns about application fidelity of the ideas and variability in implementation quality are strong, leading to a new project specifically designed to monitor implementation of MI in classrooms where positive impacts have been reported.

### *The Purdue Three-Stage Enrichment Model for Elementary Gifted Learners (PACE) and The Purdue Secondary Model for Gifted and Talented Youth*

The concept of a three-stage model initiated by Feldhusen and his graduate students was first introduced as a course design for university students in 1973; it evolved into The Three-Stage Model by 1979 (Feldhusen & Kolloff, 1979). The model is primarily an ordered enrichment model that moves students from simple thinking experiences to complex independent activities (Feldhusen and Kolloff, 1986; Feldhusen, Kolloff, Cole & Moon, 1988). Stage I focuses on the development of divergent and convergent thinking

skills; Stage II provides development in creative problem solving, and Stage III allows students to apply research skills in the development of independent study skills. The Purdue Secondary Model is a comprehensive structure for programming services at the secondary level. It has eleven components supporting enrichment and acceleration options with each component designed to act as a guide for organizing opportunities for secondary gifted students. They are: (1) counseling services, (2) seminar, (3) advanced placement courses, (4) honors classes, (5) math-science acceleration, (6) foreign languages, (7) arts, (8) cultural experiences, (9) career education, (10) vocational programs, and (11) extra-school instruction (Feldhusen & Robinson-Wyman, 1986).

Research has documented gains with regard to enhancement of creative thinking and self-concept using the Three-Stage Enrichment model for elementary gifted students (Kolloff & Feldhusen, 1984), and one study was conducted documenting limited long-term gains of the elementary program PACE (Moon & Feldhusen, 1994; Moon, Feldhusen & Dillon, 1994).

The application and implementation of either the elementary or secondary models are not conclusive yet appear to be sustainable (Moon, Feldhusen, Powley & Nidiffer, 1993; Moon & Feldhusen, 1994). Teacher training has accompanied the site implementation of both the elementary and secondary models; however, it is difficult to ascertain the degree of widespread application beyond the state of Indiana. Neither model utilizes a scope and sequence and may not be viewed as a comprehensive model in terms of applying broadly to all areas of the curriculum, all types of gifted learners or to all stages of development.

### *The Grid*

The Grid was a model designed to facilitate the curriculum developer's task of what constitutes differentiated curriculum and how one can construct such a curriculum. The model uses the components of process, content and product organized around a theme. Content is defined as "the relationship between economic, social, personal and environmental displays of power and the needs and the interests of individuals, groups, and societies (interdisciplinary)" (Kaplan, 1986). The process component utilizes productive thinking, research skills and basic skills; the product component culminates the learning into a mode of communication.

Research has not been conducted to support the effectiveness of this model with a target population. The quality of the curriculum products that have been produced based upon this model has not been reported in the literature; however, there has been extensive implementation of the approach both at state and local levels.

Teacher training has been conducted throughout the United States initially through the National/State

Leadership Training Institute and now independently by the developer so that practitioners can learn how to implement it; thousands of teachers have developed their own curriculum based upon the model. The Grid is intended as a developmental framework for curriculum planning for gifted learners, but it does not contain a scope and sequence; additionally, within the model itself, no provisions are explicitly made for accelerated learning.

### *The Matrix*

The Matrix model was developed to categorize content, process, environmental, and product dimensions of an appropriate curriculum for the gifted; it represents a set of descriptive criteria that may be used to develop classroom-based curriculum (Maker, 1982; Maker & Nielson, 1996). Recent work on the model primarily represents an enhancement of the problem solving component of it. The Discover project is a process for assessing problem solving in multiple intelligences (Maker, 1993); the problem-solving matrix incorporates a continuum of five problem types for use within each of the intelligences; Types I and II require convergent thinking. Type III problems are structured but allow for a range of methods to solve them and have a range of acceptable answers. Type IV problems are defined but the learner selects a method for solving and establishing evaluation criteria for the solution. Type V problems are ill structured and the learner must define the problem, discover the method for solving and establish criteria for creating a solution (Maker, Nielson & Rogers, 1994). The project is typically used by teachers for curriculum planning and assessing learner problem-solving abilities.

Research is currently underway involving 12 classrooms in a variety of settings; however, to date the results have not been published. A pilot study has shown that use of the matrix enhances the process of problem solving (Maker, Rogers, Nielson & Bauerle, 1996); studies to evaluate the long-term validity of the process are in progress.

School systems in several areas have applied the matrix as a framework for organizing and developing classroom level curriculum; there is evidence of individual teacher-developed curriculum, and teachers have been receptive to its use; some training exists for its application. The sustainability of the matrix for at least three years is not known; it is not comprehensive in nature, yet it does have a strong emphasis in its relationship to core subject domains.

### *The Structure of Intellect Model (SOI)*

The Structure of Intellect Model (SOI) for gifted education was based upon a theory of human intelligence called the Structure of Intellect (SI) developed by J. P. Guilford (1967); the SI model of human intelligence describes ninety kinds of cognitive func-

tions organized into content, operation and product abilities. The SOI system applies Guilford's theory into the areas of assessment and training. The model is definable as a system and applies broadly to all types of gifted learners at varying developmental stages but due to its comprehensiveness and emphasis on cognition, only a few sites have actually implemented the model (Meeker, 1985). Those sites have used it for identifying students or for training teachers to view intelligence as a non-fixed entity.

Studies of the model do not include effectiveness data (Meeker, 1976); rather they primarily focus on findings for use as identification criteria or as a means for organizing information about a gifted child or for overall program design. SOI has been successfully used in selected sites for identification of culturally diverse students (Hengen, 1983) and preschool screening for multi-ethnic disadvantaged gifted students (Bonne, 1985).

Although now somewhat dated, SOI offered a means of understanding students by delineating profiles of their intellectual abilities. It contained a teacher training component that used teacher modules that were designed to train one SOI ability at a time. Training materials included mini lesson plans for group teaching and self-help modules for individualized instruction with selected students (Meeker, 1969).

### *The Models for Talents Unlimited, Inc. and Talents Unlimited to the Secondary Power (TU<sup>2</sup>)*

Talents Unlimited (Schlichter, 1986b) was also based upon Guilford's (1967) research on the nature of intelligence. Taylor and colleagues (Taylor, Ghiselin, Wolfer, Loy & Bourne, 1964), also influenced by Guilford, authored The Multiple Talent Theory, which precipitated the development of a model to be employed in helping teachers identify and nurture students' multiple talents. Talents Unlimited features four major components: (1) a description of specific skill abilities or talents, in addition to academic ability, that include productive thinking, communication, forecasting, decision making, and planning; (2) model instructional materials; (3) an inservice training program for teachers; and (4) an evaluation system for assessing students' thinking skills development (Schlichter, 1986b). Talents Unlimited Inc. is the K-6 model and Talents Unlimited to the Secondary Power is a model for grades 7-12 (Crump, Schlichter & Palk, 1988; Schlichter, Hobbs & Crump, 1988).

Research has documented gains using the model in developing students' creative and critical thinking (Schlichter & Palmer, 1993). Additionally, there is evidence that the use of the model enhances academic skill development on standardized achievement tests (McLean & Chisson, 1980); however, no longitudinal studies have been conducted.

Staff development and teacher training constitute a strong component of the model (Schlichter, 1986a;

Schlichter et al, 1997); teachers may become 'certified' as Talents Unlimited trainers. Due to the strong emphasis on teacher training, Talents Unlimited has widespread applicable student use across the United States and worldwide. Part of its implementation success came as a result of funding and membership in the United States Office of Education, National Diffusion Network.

The model has been used most effectively as a classroom-based approach with all learners (Schlichter, 1988), thus rendering it less differential for the gifted in practice than some of the other models.

### *The Triarchic Componential Model*

The triarchic componential model of curriculum is based upon an information processing theory of intelligence (Sternberg, 1981). In the metacomponent area, three components must be present in mental processes used in thinking. The executive process component is used in planning, decision making and monitoring performance. The performance component processes are used in executing the executive problem-solving strategies within domains. The knowledge-acquisition component is used in acquiring, retaining, and transferring new information. The interaction and feedback between the individual and his/her environment within any given context allows cognitive development to occur.

An initial study has shown the effectiveness of the triarchic model with students learning psychology in a summer program (Sternberg & Clinkenbeard, 1995); more recent work has been conducted in studies using psychology as the curriculum base with larger samples of students. Students continue to show growth patterns when assessment protocols are linked to measuring ability profiles (Sternberg, Ferrari, Clinkenbeard & Grigorenko, 1996). Primary to these studies is the validation of the STAT (Sternberg Triarchic Abilities Test) and its utility for finding students strong on specific triarchic components; other recent studies (Sternberg, Torff, and Grigorenko, 1998a, 1998b) focus on the use of triarchic instructional processes in classrooms at the elementary and middle school levels. Results suggest slightly stronger effects for triarchic instruction over traditional and critical thinking approaches. Descriptions of teacher-created curriculum and instructional instrumentation processes were limited but are clearly organized along discipline-specific lines of inquiry; sustainability of the curriculum model beyond summer program implementation and pilot settings is not known.

There is not a packaged teacher training or staff development component, partially because the model is based upon a theory of intelligence rather than a deliberate curriculum framework; it is a systemic but

not a comprehensive model with applications made in selected classrooms.

### *The William and Mary Integrated Curriculum Model (ICM)*

The Integrated Curriculum Model (ICM) (Van Tassel-Baska, 1986) was specifically developed for high ability learners and has three dimensions: (1) advanced content, (2) high level process and product work, and (3) intra- and interdisciplinary concept development and understanding. VanTassel-Baska, with funding from the Jacob Javits Program, developed specific curriculum frameworks and underlying units in language arts, science and social studies, using the ICM.

Research has been conducted to support the effectiveness of these curriculum units with gifted populations within a variety of educational settings. Specifically, significant growth gains in literary analysis and interpretation, persuasive writing, and linguistic competency in language arts have been demonstrated for experimental gifted classes using the developed curriculum units in comparison to gifted groups not using them (Van Tassel-Baska, Johnson, Hughes & Boyce, 1996; Van Tassel-Baska, Zuo, Avery and Little, in press). Other studies have shown that using the problem-based science units embedded in an exemplary science curriculum significantly enhances the capacity for integrating higher order process skills in science regardless of the grouping approach employed (Gallagher, Stepien, Sher & Workman, 1995; Boyce, VanTassel-Baska, Burruss, Sher & Johnson, 1997; Van Tassel-Baska, Bass, Ries, Poland & Avery, 1998). Further, research has documented positive change in teacher attitude, student motivational response, and school and district change (Van Tassel-Baska, Avery, Little & Hughes, 2000) as a result of using the William and Mary curriculum over three years.

Teacher training is an integral component of the ICM; training workshops have been conducted in 30 states, and The College of William and Mary offers training annually. There is a strong relationship to core subject domains as well as national standards alignment; the curriculum based on the model was developed using the national standards work as a template. Alignment charts have been completed for national and state standards work in both language arts and science.

The William and Mary units are moderately comprehensive in that they span grades 2–10 in language arts and 2–8 in science. New language arts units developed in 1997–98 now offer K–11 coverage in language arts; the ICM has been used for specific district curriculum development and planning.

There is evidence of broad-based application but some question remains as to the ease of implementa-

tion of actual teaching units and to the fidelity of implementation by teachers (Burruss, 1997); some districts use the units as models for developing their own curriculum. The developer reported that 100 school districts are part of a National Curriculum Network using both the science and language arts units; data have been collected from over 100 classrooms nationally on student impact.

Studies of effectiveness are on-going in classrooms nationally, and the curriculum is reported to be used in 45 states. Internationally, the model is being used in 15 countries with systematic unit development occurring in two states in Australia.

### *Findings*

Seven models showed evidence of research being conducted on them; of those, six of the models employed comparison groups where treatment might be attributed to the curriculum approach employed. The Stanley, Renzulli, Feldhusen, Sternberg, VanTassel-Baska, and Schlichter models all have some evidence of effectiveness with gifted populations in comparison to other treatments. However, only Stanley has amassed a comprehensive body of literature to support his model. While the Talents Unlimited Model has some evidence of effectiveness, much of it is on non-gifted populations.

Evidence for the translation of these curriculum models into effective practice varies considerably; seven models have training packages that provide staff development for implementation; only four models explicitly consider scope and sequence issues. The Autonomous Learner Model (ALM) and SEM consider scope and sequence within their model. For the ALM, it is in the movement from one stage to another; for SEM, it occurs within Type II activities. Both talent search and ICM have developed scope and sequence models linked to Advanced Placement work; ICM has also developed alignment models to the national standards projects and 15 state frameworks as well.

Data on curriculum and instructional practices with the gifted clearly favor accelerative approaches in the core subject areas of language, arts, science, and mathematics, although the approach to content acceleration may vary. While both the talent search and ICM models have elements of acceleration within them, only the talent search model has empirically demonstrated the strong impact of accelerative study on learning.

Curriculum organized around higher order processes and independent study have yielded few studies of student impacts, nor are the findings across studies consistent; even longitudinal studies, such as those on the PACE and SEM models, have produced limited evidence of outcomes relevant to clear student gains. Limited sample size and other confounding variables such as lack of comparison groups also render these studies less credible.

### *Conclusions*

A strong body of research evidence exists supporting the use of advanced curriculum in core areas of learning at an accelerated rate for high ability learners; some evidence also exists that more enrichment-oriented models are effective; this conclusion has not changed much in the past 20 years (Daurio, 1979). Moreover, recent meta-analytic studies continue to confirm the superior learning effects of acceleration over enrichment in tandem with grouping the gifted (Kulik & Kulik, 1992). In comparison to strategies such as independent study, various modes of grouping, and problem-solving, acceleration also shows superior effect sizes (Walberg, 1991). Despite the lack of convincing research to support their use, several of the enrichment models enjoy widespread popularity and are used extensively in schools.

### *Implications*

Several implications might be drawn from these findings, related to both research and practice in gifted education. Research-based practice is critical to defensible gifted programs; therefore, practitioners must proceed carefully in deciding on curriculum for use in these programs. The evidence strongly suggests that content-based accelerative approaches should be employed in any curriculum used in school-based programs for the gifted and that schools need to apply curriculum models faithfully and thoroughly enough to realize their potential impacts over time.

In the area of research, it is clear that there is a limited base of coherent studies that can make claims about the efficacy of enriched approaches to curriculum for the gifted. Thus an important direction for future research would be to conduct curriculum intervention studies, testing the extant models as well as replicating existing studies to build a base of deeper understanding about what works well with gifted students in school programs. More research on differential student learning outcomes in gifted programs, using discrete curricular approaches clearly needs to be undertaken. The field of gifted education has a long way to go before being able to say "what intervention works best with what type of gifted learner at what stage of development?" Future research efforts need to define at a more discrete level the impacts of curriculum interventions on the prototypes of gifted learners that inhabit our schools.

### *The relationship of curriculum for the gifted to general school reform initiatives*

The standards-based educational reform movement in the United States and abroad has been instrumental in underscoring the need for curriculum development work (Cohen & Spillane, 1993; O'Day & Smith, 1993). This movement advocates the articulation of challenging content standards which become the basis

for the alignment of policies, practices, and resources directed toward student proficiency in meeting or exceeding the standards (McLaughlin & Shepard, 1995). At national and state governance levels, these standards serve as the foundation for establishing policies and distributing resources across districts and schools. At the district level, the standards facilitate the design of curriculum frameworks to guide the curriculum and staff development initiatives. At the classroom level, the content standards are translated into specific curriculum and instructional units.

After a decade of work on analysis, design and development of curriculum for the gifted learners that is consonant with state and national curriculum standards in the United States and other countries it appears that there is goodness of fit between the standards for all and the components of a desirable curriculum for the gifted.

The similarities between curriculum development efforts in general education, and the principles of gifted education curriculum development are very complementary. While the translation of these principles into practice still require greater flexibility and latitude when dealing with the range of high ability learners, it is important to note the commonalities of general approaches to curriculum reform with those principles of good gifted education. Both approaches value learner outcomes that emphasize higher level thinking and conceptual understanding, authentic instruction and assessment, deep involvement in inquiry, use of multiple resources and technology applications, and helping students develop metacognitive tools. The standards also reflect an attempt to view the curriculum experience as one that promotes the habits of mind of a practicing professional, whether it be a scientist, writer or mathematician; all of these components have been staples of gifted curriculum philosophy for the past 20 years. Because of the complementarity of discipline-specific reform efforts and gifted education tenets, educators of the gifted should align their efforts in curriculum with the work currently going on in all the content disciplines. As a field, gifted education has much to contribute to the debate on national and international standards in all of the core domains of inquiry.

While there is considerable overlap in the proposed exemplary content-based curriculum for all learners and curriculum differentiation issues for the gifted, there still remain two issues that must be accounted for in working with the gifted. The differentiation for these learners in such a model must still emanate from a clear understanding of the capacity of such learners at a given grade level to engage in a faster pace of learning at an advanced level. Moreover, high ability learners require access to more sophisticated curriculum treatment at earlier stages of development. Consequently, curriculum expectations for these students need to reflect such adaptations, at advanced and even world

class levels. Curriculum grounded in intra- and interdisciplinary concepts, however, provides enormous opportunities to enhance more advanced and sophisticated learning for gifted students.

Based on the thorough review of existing subject matter materials, it appears appropriate to underscore the extent to which cost-effective exemplary curriculum materials are readily available for use in classrooms. One problem uncovered, however, was the very limited use those materials were receiving, even in schools and districts that have purchased them (Johnson, Boyce & VanTassel-Baska, 1995). Some of the best materials may be characterized as unlevelled in respect to grade, interdisciplinary in orientation, and comprised of multiple modes of learning, usually including video or computer technology as a key feature. It is paradoxical that the very curricular components valued for their appropriateness with high ability learners are overlooked when they are 'packaged' into ready-made curriculum materials. The lesson to be learned may be that there already are excellent curricula for high ability and other learning groups; the problem rests with: (a) continuing the development process through extending and refining that which is already available using existing frameworks, and (b) removing barriers (such as lack of experimental materials and/or equipment and lack of human resource assistance in implementing classroom procedures) to getting the new curriculum institutionalized in classroom practice.

Many basal text materials are inadequate for the task of curriculum reform, especially for high ability learners. For example, in the 1995 study cited, no basal text reached the level of being recommended for use with high ability learners with the exception of the BSCS biology program originally developed in the 1960s. There is a clear need for schools to select materials carefully that respond to the more powerful current curricular models in general and gifted education in particular.

Developmental and ability levels of students appear to impact on the use of new curriculum materials but not to the degree anticipated by many educators. The William and Mary curriculum units, for example, were pilot tested in various classroom settings: gifted self-contained, resource rooms, high ability classes, and heterogeneous classrooms. Teachers who worked with gifted students daily reported greater success with the curriculum than did those who saw students only once or twice a week. Based on teacher log data, it was found that high ability learners were more receptive to the curriculum than other learners; however, some students *not* identified as gifted displayed aptitude and interest through the use of the materials, and teachers felt that most learners benefitted more from the approaches embedded in this curriculum than from a traditional text model (VanTassel-Baska, Bass, Reis, Poland & Avery, 1998). This finding tends to support

the premise that more high-powered curriculum in regular classrooms would enhance the learning for all.

Clearly the major thrust in curriculum reform in all areas for high ability learners must be in the arena of teacher training; the need for specific subject matter training is great, given the need to attend to discipline-specific reform and rigorous curriculum for the gifted. In science, for example, all teachers are teachers of the high ability learner, except in special schools or self-contained classes; thus the need to engage with general science educators in their staff development efforts to reform science education for all learners may be a crucial part of our role as educators of the gifted.

Teacher training for gifted learners also needs to target specialized concerns. In respect to curriculum in general, preservice and inservice work needs to focus on how to implement discipline-specific models of curriculum and instruction that are responsive to the underlying needs of gifted learners, how to engage learners as investigators, providing the tools and processes used by real world problem solvers, and how to raise standards and expectations for gifted learners in regular classrooms.

### *Curriculum Issues for Special Populations of Gifted Learners*

Whether we are talking about low income, minority, or disabled gifted students, one factor remains common to each group; they reside outside the mainstream networks that provide access to educational advantage. This knowledge is crucial to converting high aspirations into creative productive achievement at various stages of development; thus the role of special programs is critical to this conversion process.

At their best, in-school programs have provided rigorous coursework comparable to what advantaged learners in the best school settings would receive. At the same time, other school programs have focused on remediating skill deficits or offering programs in non-academic areas, such as the performing arts. A survey of existing programs for disadvantaged gifted students at the local level identified over 100 districts thought to be providing service (VanTassel-Baska, Patton & Prillaman, 1991). The majority of these programs were not differentiating service delivery for disadvantaged gifted students, even though they were careful to include them in programs for gifted students.

Yet there is evidence from the general literature on disadvantaged populations of the importance of key differential interventions with these learners based on the variables that separate them from their more advantaged peers in the first place. These needed interventions include early education, classroom environment, curriculum, and counseling.

Historically, the Upward Bound program, which assists high school students in preparing for college, emphasized language-based skills such as reading, composition, ethnic literature, and creative writing

(Koe, 1980). Yet recent curriculum concerns have centered on the paucity of minority students pursuing advanced programming in math and science. Anick, Carpenter & Smith (1981) noted that serious inequities exist in math education of Black and Hispanic students and that their achievement levels were not only well below the national average, but that differences from the larger population increased for each consecutive age group. Their study showed though, that while Blacks appear to take less math than other groups, they reported positive feelings about the subject. The authors concluded that motivation may not be a major problem and that general approaches used for all students would be appropriate for minorities.

In a review of 24 studies of participation and performance of minorities in math done since 1975, Mathews (1984) found that parents desire but often do not know how to help their children, that minority role models appear to have a positive effect on enrollment in math courses, and that math may be seen as lacking utility by lower SES children.

Several researchers have focused on group rather than individual models of learning as more facilitative for minority group students. Slavin & Oickle (1981) found a greater increase in black students' academic performance when cooperative learning groups were used; Hale-Benson (1986) advocated peer tutoring, while Holliday (1985) emphasized enhanced teacher-student interactions.

The literature has suggested several differentiated approaches for working with gifted learning disabled children, including separate class grouping (Daniels, 1983), counseling and adaptive behavior programs (Wolf & Gygi, 1981), the use of technological aids (Tobin & Schiffman, 1983), after-school structured timetables (Sah & Borland, 1989), and the teaching of compensation strategies (Suter & Wolf, 1987). Moreover, most writers also urge the use of strategies appropriate for all gifted learners. A list of adaptations for use at school and home to enhance learning for gifted learning disabled students include: use visuals and hands-on experiences; provide a quiet place for work; use a sight approach to reading rather than phonics; use a word processor with a spell correct program; practice visualization as a memory aid; tape record lectures instead of taking notes; and concentrate on the child's strengths, especially in order to compensate for weaknesses (Hansford et al., 1987; Suter & Wolf, 1987; Silverman, 1989).

While the research base on the under-representation of low-income and culturally diverse gifted learners was fairly substantial, there were fewer studies that reported on educational practices addressing their needs. VanTassel-Baska et al. (1991) synthesized the generic features of interventions that work well with disadvantaged and culturally different gifted students: (1) early and systematic attention to their needs, (2) parental and family involvement in their educational

program, (3) use of effective schools' strategies, (4) experiential and 'hands-on' learning approaches, (5) activities that allow for self-expression, (6) mentors and role models, (7) counseling that addresses cultural values and facilitates talent development, (8) building on the strengths and differential learning styles of at-risk learners. Maker and Schiever (1989) presaged many of these same elements in their earlier synthesis of the literature on programs and curricula for cultural and ethnic minorities. Their summary included the following: (1) plan the curriculum based on students' strengths, (2) provide for the development of basic skills and other abilities that the student may lack, (3) consider differences as positives, (4) arrange for mentors, and (5) create and maintain a classroom with a multicultural emphasis.

Frasier (1993) cited several examples of U.S. programs that had success in working with disadvantaged and minority gifted populations, including the Skills Re-enforcement Project (SRP) and the Program of Assessment, Diagnosis, and Instruction (PADI). Tomlinson, Callahan & Lelli (1997) found that multicultural emphases, language immersion, use of manipulatives, participation in mentorships, and family outreach were essential for the success of low-income and/or minority primary-aged gifted students in Project START (Support to Affirm Rising Talent).

Other researchers have focused on the larger cultural context for understanding the needs of specific minority groups. Clasen (1992) and Ogbu (1994) have both commented on the alienation experienced by involuntary minorities struggling to juggle the expectations of conflicting worlds. For instance, African-American gifted students, who demonstrate academic aptitude, can be rejected by their black peers for 'acting White'; as a result, these students must develop coping mechanisms in order to straddle the value systems of competing allegiances (Patton & Baytops, 1995). Such demands create additional psychological stressors in minority gifted populations that need psycho-social support (Ford-Harris, Schuerger & Harris, 1991).

In studying the needs of at-risk gifted adolescents, Olszewski-Kubilius, Grant & Seibert (1994) noted that programs that address only one aspect of the child's life, such as the provision of an appropriate academic program, have "little hope of having long-term impact" (p. 23). This underscores the need for parental involvement in the child's education. Parent involvement has been found to have a positive effect for students by providing appropriate modeling, reinforcement, and even direct instruction within a holistic context of family, school, and community (Epstein, 1995; Hoover-Dempsey & Sandler, 1995). Epstein (1995) found that developing school, family, and community partnerships improved school programs and school climate and provided a basis for connecting families to services in the community. Such refrains are

also echoed in the literature on resilience (Werner & Smith, 1992), which advocated for multifaceted, systemic interventions in the home, school, and community.

Several curricular interventions also appear promising:

- (1) Separate instructional opportunities for students with the same developmental profile. Data across special populations suggest the importance for within-group instructional time that allows for interaction based on similar conditions whether it be gender, social background, or handicapping conditions.
- (2) The use of technology, especially microcomputers, to aid in the transmission of learning for many special population learners. While it has been used most predominantly with disabled gifted learners, it holds promise for targeted use with other learners who evidence discrepant learning patterns and can profit from compensatory intervention.
- (3) The use of small group and individual counseling, mentorships, and internships for special population learners appears promising since these interventions all constitute individual attention to affective as well as cognitive issues of development.
- (4) A focus on the arts as a therapeutic intervention as well as a creative and expressive outlet appears important to consider for all of these special populations. Through the arts, the dissynchronies of one's experience can be reduced and absorbed into a higher pattern of integration. Thus it serves as an enhancement to higher level functioning for such individuals.
- (5) Use of materials rich in ideas and imagination coupled with a focus on higher level skills appears to be an important intervention approach for special populations. Both self-concept and motivation are in jeopardy if prolonged use of compensatory strategies and basic level materials are used in the educational process of these learners. Challenging content with a focus on ideas and creative opportunities are essential to combat further discrepant performance.
- (6) An emphasis on one-to-one instruction through tutorial approaches appears to be very helpful in working with gifted special populations.

Thus research on the learning needs of many of these students, particularly from African-American and Hispanic populations, has provided some guidance about program and curriculum interventions that have worked. Key features of successful programs included early identification and sustained intervention, experiential and hands-on learning, and use of curricula with multicultural emphases that allow for student choice. In addition, an awareness of the importance of parental involvement or support by a mentor who encourages

academic achievement, permeated this segment of the literature.

*Conclusion: The Challenge for the Future*

Where is curriculum and instruction for the gifted headed over the next several years? It is clear that the field of gifted education is changing: our conceptions of intelligence and therefore of giftedness have changed, our conceptions of the delivery context for serving the gifted have changed, and our population focus has also changed. This shift in focus is both a dilemma and a challenge that provides us with new opportunities to grow and develop as a field, hopefully more responsive to the individual needs of children than to preordained labels; to the social context of schools and the networks that hold them together than to the categorical approach to gifted education as a separate enterprise; and more responsive to change in general that requires us to compromise hard positions and join forces with all educators who care about students with special needs.

Curriculum planners for the gifted need to be cognizant of the importance of maintaining a balanced perspective toward key issues if gifted education is to be meaningful for the students it wants to serve. The theme for approaching and dealing with these issues is that of balance—a balance that must be effected between alliances with general and special education models without diffusing efforts to maintain a distinguishable set of curriculum principles that are appropriate *only* for gifted learners. One of the dangers of stretching to reach out to the more entrenched curriculum models of general education or the specialized administrative models of special education is a loss of identity in what gifted education itself represents. If it is shown by current research efforts that the degree of exceptionality is not sufficiently great enough to warrant a special administrative structure and special settings for gifted learners, then our claims as a field to separate program considerations becomes weakened. If at the same time, it is sufficiently demonstrated that exemplary approaches to curriculum in general education are in fact both necessary and sufficient for gifted learners, then our claims to a qualitatively different set of educational experiences for the gifted are weakened. While we as a field may have made too much of our distinctiveness and specialness, by the same token we must guard against too quickly abandoning the very principles on which the field has been grounded for the last 80 years—the basic principles of the gifted student's unique needs that call for acceleration, grouping, and enrichment in school settings in order to receive an appropriate education.

Balance is also important in considering the needs of learners who are gifted in all cognitive areas in comparison to those gifted only in one; how do we provide appropriate curricular experiences for specialized talents as well as provide comprehensive

services to more broad-based ones? This issue is particularly worthy of our reflection at the level of developing a curriculum scope and sequence. Should the outcome expectations of secondary school for the science-prone, for example, differ from the expectations for the intellectually gifted student whose interests and aptitudes are more broad-ranging? If they should, how might these differential expectations be articulated K-12? Or should specialized talent development even be a function of the public school arena? Certainly Bloom's work on talent development (1985) would support the contention that it has not been traditionally a part of what public schools have taken on as their responsibility. Perhaps it is in the specialized areas of talent—art, music, mathematics, chess—where the school's major role may be that of broker and facilitator of talent development for students who show early promise. It is for these learners that tutorials, mentorships, and internships in the larger community are reserved since their aptitudes and interests are more finely attuned to the need for individualized adult expert instruction early.

Balance is also a theme in our consideration of the domains of study to be valued in a comprehensive curriculum for gifted learners. The aesthetic, and social domains of study deserve as much attention as the cognitive in the overall development of the gifted learner (VanTassel-Baska, 1998). This balanced perspective on curriculum development is needed lest we limit the recognition of the integrated needs of the gifted learner and narrow the educational options available to her. Inclusion of the arts, for example, in a curriculum for the intellectually gifted is significant because it provides a vehicle for the development of aesthetic appreciation and an expressive outlet that enhances the creative impulse. Scientists foreshadow discoveries in metaphors and visual symbols; mathematicians strive for elegance in form; philosophers value the symmetry of an argument. In most professional fields at high levels of creative work, the aesthetic and artistic aspects of the work come strongly into focus. Thus to ensure that curriculum for gifted learners is heavily infused with such an emphasis throughout their schooling years seems vital.

Honoring the affective development of the gifted is also an important aspect of a comprehensive balanced curriculum view. These students need to understand their own exceptionality, their intensity and sensitivity of feelings, their need for coping strategies to help them deal with their own perfectionism and vulnerability. These needs require a strong affective orientation to the curriculum to be delivered by teachers sensitive to the nature of gifted students. Such needs also demand a set of counseling services that can respond to psychosocial, academic planning, and career planning needs at requisite periods during schooling.

Another facet to a balanced view of curriculum for the gifted is in the area of social development,

undertaken with the long view toward adult leadership. While much of the work in leadership curriculum for the gifted has focused on political leadership (e.g. Karnes & Chauvin, 2000), there is a need to expand our thinking in this area to embrace a concept of leadership that recognizes the other forms of leadership that gifted individuals in a society provide including intellectual leadership in various areas and for many gifted women, social service leadership. The skills of understanding group dynamics, the organization of complex tasks, and how to motivate others, however, are fundamental to all forms of leadership and thus must underlie a curriculum in this area.

Another issue related to a balanced perspective in curriculum planning for the gifted rests with a need to view our purposes in constructing specialized curriculum for gifted learners. We have often argued that differentiating curriculum for the gifted was important to meet individual needs, yet we also view the potential contribution of the gifted to society as an equally important purpose. The metaphor of the gifted as national resource has been exploited more than once in our history as a field; in the policy arena, at least, it seems important to be able to keep these purposes in a healthy tension that allows for both views to be made explicit. For, at a fundamental level, the gifted develop as individuals in a reciprocal relationship with their society; thus their creative work carries meaning beyond themselves whether it is fully intended to or not. By the same token, a society is enriched by having individuals actively engaging in self-chosen creative endeavors.

The translation of this paradox of individual and societal needs at the classroom level can be seen in the issue of cooperative learning and the gifted. To what extent does the use of the gifted learner as a tutor/teacher/model to others in group settings become exploitation and costly to their own individual development? To what extent does prolonged independent or homogeneous group work carried out in isolation contribute to a rejection by the gifted of their natural connection to other learners in the classroom? Again the healthy balance must be struck between independent and group opportunities in order to ensure the full development of the gifted learner in a social context. Can we tolerate individual excellence within a social framework that honors the integrity of everyone and is hospitable to all learners? This it seems is the fundamental question in school classrooms today.

As curriculum planners reflect on these somewhat traditional issues, they must not reject their importance in favor of the more 'trendy questions' that may be asked. For if curriculum planning is to have merit, then the need for a balanced perspective in the areas of general and specialized talent development, equal valuing of cognitive, affective, aesthetic, and social development of the gifted, and a concern for both individual and social contributions must be satisfied.

For groups of typical gifted learners as well as individual-need gifted learners, such as those from special populations, attention to these issues is crucial. Curriculum for the gifted, its goals and purposes, as well as its delivery systems speaks loudly as to how talent and its development is honored and nurtured in a society.

# The Schoolwide Enrichment Model<sup>1</sup>

Joseph S. Renzulli\* and Sally M. Reis†

## Introduction

Enrichment programs for gifted and talented students have been the true laboratories of the world's schools because they have presented ideal opportunities for testing new ideas and experimenting with potential solutions to long-standing educational problems. Programs for high potential students have been an especially fertile place for experimentation because such programs are not usually encumbered by prescribed curriculum guides or traditional methods of instruction. It was within the context of these programs that the thinking skills movement first took hold in American education, and the pioneering work of notable theorists such as Benjamin Bloom, Howard Gardner, and Robert Sternberg first gained the attention of the education community. Other developments that had their origins in special programs are currently being examined for general practice. These developments include: a focus on concept rather than skill learning, the use of interdisciplinary curriculum and theme-based studies, student portfolios, performance assessment, cross-grade grouping, alternative scheduling patterns, and perhaps most important, opportunities for students to exchange traditional roles as lesson-learners and doers-of-exercises for more challenging and demanding roles that require hands-on learning, first-hand investigations, and the *application* of knowledge and thinking skills to complex problems.

The Schoolwide Enrichment Model (SEM) is a detailed blueprint for total school improvement that allows each school the flexibility to allow each school

to develop its own unique programs based on local resources, student demographics, and school dynamics as well as faculty strengths and creativity. Although this research-based model is based on highly successful practices that originated in special programs for the gifted and talented students, its major goal is to promote both challenging and enjoyable high-end learning across a wide range of school types, levels and demographic differences. The idea is to create a repertoire of services that can be integrated in such a way to create "a rising tide lifts all ships" approach. This approach allows schools to develop a collaborative school culture that takes advantage of resources and appropriate decision-making opportunities to create meaningful, high-level and potentially creative opportunities for students to develop their talents. SEM suggests that educators should examine ways to make schools more inviting, friendly, and enjoyable places that encourage the full development of the learner instead of seeing students as a repository for information that will be assessed with the next round of standardized tests. Not only has this model been successful in addressing the problem of students who have been under-challenged but it also provides additional important learning paths for students who find success in more traditional learning environments.

The present reform initiatives in general education have created a more receptive atmosphere for enrichment approaches that challenge all students, and accordingly, the Enrichment Triad Model has evolved over the last 20 years based on the previous experiences and current changes in general education. The evolution of the Enrichment Triad Model will be described in this chapter as well as the newest adaptation of the Schoolwide Enrichment Model including a description of the school structures upon which the model is targeted and the three service delivery components.

The original Enrichment Triad Model (Renzulli, 1976) was developed in the mid-1970s and initially implemented by school districts primarily in Connecticut in the United States. The model, which was originally field tested in several districts, proved to be quite popular and requests from all over the United

---

<sup>1</sup> Research for this chapter was supported under the Javits Act Program (Grant No. R206R00001) as administered by the Office of Educational Research and Improvement, U.S. Department of Education. Grantees undertaking such projects are encouraged to express freely their professional judgment. This report, therefore, does not necessarily represent positions or policies of the Government, and no official endorsement should be inferred.

States for visitations to schools using the model and for information about how to implement the model increased. A book about the Enrichment Triad Model (Renzulli, 1977) was published, and more and more districts began asking for help in implementing this approach. It was at this point that a clear need was established for research about the effectiveness of the model and for practical procedures that could provide technical assistance for interested educators to help develop programs in their schools. We had become fascinated by the various kinds of programs being developed by different types of teachers. In some programs, for example, teachers consistently elicited high levels of creative productivity in students while others had *few* students who engaged in this type of work. In some districts, many enrichment opportunities were regularly offered to students not formally identified for the program, while in other districts only identified 'gifted' students had access to enrichment experiences. We wondered how we could replicate the success of one teacher or one district in implementing the model. For example, if one teacher consistently produced high levels of creative productivity in students, how could we capture that technology and replicate it in other teachers? And if certain resources proved to be consequential in promoting desirable results, how could we make these resources available to larger numbers of teachers and students?

In the more than two decades since the Enrichment Triad Model has been used as the basis for many educational programs for gifted and talented students, an unusually large number of examples of creative productivity have occurred on the parts of young people whose educational experiences have been guided by this programming approach. Perhaps, like others involved in the development of theories and generalizations, we did not fully understand at the onset of our work the full implications of the model for encouraging and developing creative productivity in young people. These implications relate most directly to teacher training, resource procurement and management, product evaluation, and other theoretical concerns (e.g. motivation, task commitment, self-efficacy) that probably would have gone unexamined, undeveloped, and unrefined without the favorable results that were reported to us by early implementers of the model. We became increasingly interested in how and why the model was working and how we could further expand the theoretical rationale underlying our work, and the population to which services could be provided. Thus, several years of conceptual analysis, practical experience, and an examination of the work of other theorists, has brought us to the point of tying together the material in this chapter, which represents approximately twenty years of field testing, research, evolution and dissemination.

In this chapter, an overview of the conception of giftedness upon which this model is based is presented,

and a description of the original Enrichment Triad Model is provided as is a chronology of how the model has expanded and changed. Research about the model is presented as is a brief summary of research dealing with selected studies about student creative productivity. In the final section, new directions for the model are presented along with suggestions for future directions for research on creative productivity.

### A Broadened Conception of Giftedness

The field of gifted education, like any other specialized area of study, represents a spectrum of ideologies that exists along a continuum ranging from conservative to liberal points of view. *Conservative* and *liberal* are not used here in their political connotations, but rather according to the degree of restrictiveness that is used in determining who is eligible for special programs and services.

Restrictiveness can be expressed in two ways; first, a definition can limit the number of specific performance areas that are considered in determining eligibility for special services. A conservative definition, for example, might limit eligibility to academic performance only, and exclude other areas such as music, art, drama, leadership, public speaking, social service, creative writing or skills in interpersonal relations. Second, a definition can limit the degree or level of excellence that one must attain by establishing extremely high cutoff points.

Although liberal definitions have the obvious advantage of expanding the conception of giftedness, they also open up two theoretical concerns by introducing: (1) a values issue (How do we operationally define broader conceptions of giftedness?) and (2) the age-old problem of subjectivity in measurement. In recent years the values issue has been largely resolved. Very few educators cling tenaciously to a 'straight IQ' or purely academic definition of giftedness. 'Multiple talent' and 'multiple criteria' are almost the bywords of the present-day gifted education movement, and most people have little difficulty in accepting a definition that includes most areas of human activity which are manifested in socially useful forms of expression.

The problem of subjectivity in measurement is not as easily resolved. As the definition of giftedness is extended beyond those abilities that are clearly reflected in tests of intelligence, achievement, and academic aptitude, it becomes necessary to put less emphasis on precise estimates of performance and potential and more emphasis on the opinions of qualified persons in making decisions about admission to special programs. The crux of the issue boils down to a simple and yet very important question: How much of a trade-off are we willing to make on the objective to subjective continuum in order to allow recognition of a broader spectrum of human abilities? If some degree of subjectivity cannot be tolerated, then our definitions of giftedness and the resulting programs

will logically be limited to abilities that can be measured only by objective tests.

### Two Kinds of Giftedness

It is generally accepted that intelligence is not a unitary concept, but rather there are many kinds of intelligence and therefore single definitions cannot be used to explain this multifaceted phenomenon (Neisser, 1979). The confusion and inconclusiveness about present theories of intelligence has led Sternberg (1984) and others to develop new models for explaining this complicated concept. Sternberg's 'triarchic' theory of human intelligence consists of three subtheories: a contextual subtheory, which relates intelligence to the external world of the individual; a two-facet experiential subtheory, which relates intelligence to both the external and internal worlds of the individual; and a componential subtheory, which relates intelligence to the internal world of the individual. Gardner (1983) proposed seven distinctive types of intelligent behavior which he called linguistic, logical-mathematical, spatial, bodily-kinesthetic, musical, interpersonal, intrapersonal, and the recently added naturalist intelligence.

In view of these recent works and numerous earlier cautions about the dangers of trying to describe intelligence through the use of single scores, it seems safe to conclude that this practice has been and always will be questionable. At the very least, attributes of intelligent behavior must be considered within the context of cultural and situational factors. Indeed, some of the most recent examinations have concluded that "[t]he concept of intelligence *cannot* be explicitly defined, not only because of the nature of intelligence but also because of the nature of concepts" (Neisser, 1979, p. 179).

There is no ideal way to measure intelligence and therefore we must avoid the typical practice of believing that if we know a person's IQ score, we also know his or her intelligence. Even Terman warned against total reliance on tests: "We must guard against defining intelligence solely in terms of ability to pass the tests of a given intelligence scale" (as cited in Thorndike, 1921, p. 131). E. L. Thorndike echoed Terman's concern by stating "to assume that we have measured some general power which resides in [the person being tested] and determines his ability in every variety of intellectual task in its entirety is to fly directly in the face of all that is known about the organization of the intellect" (Thorndike, 1921, p. 126).

The reason we have cited these concerns about the historical difficulty of defining and measuring intelligence is to highlight the even larger problem of isolating a unitary definition of giftedness. At the very least, we will always have several conceptions (and therefore definitions) of giftedness. To help in this

analysis, we will begin by examining two broad categories of giftedness that have been dealt with in the research literature: 'schoolhouse giftedness' and 'creative-productive giftedness'. Before describing each type, we want to emphasize that:

- (1) Both types are important.
- (2) There is usually an interaction between the two types.
- (3) Special programs should make appropriate provisions for encouraging both types of giftedness as well as the numerous occasions when the two types interact with each other.

### Schoolhouse Giftedness

Schoolhouse giftedness might also be called test-taking or lesson-learning giftedness. It is the kind most easily measured by IQ or other cognitive ability tests, and for this reason it is also the type most often used for selecting students for entrance into special programs. The abilities people display on IQ and aptitude tests are exactly the kinds of abilities most valued in traditional school learning situations. In other words, the tasks required in ability tests are similar in nature to tasks that teachers require in most lesson-learning situations. A large body of research tells us that students who score high on IQ tests are also likely to get high grades in school, and that these test-taking and lesson-learning abilities generally remain stable over time. The results of this research should lead us to some very obvious conclusions about schoolhouse giftedness: it exists in varying degrees, it can be identified through standardized assessment techniques, and we should therefore do everything in our power to make appropriate modifications for students who have the ability to cover regular curricular material at advanced rates and levels of understanding. Curriculum compacting (Renzulli, Smith & Reis, 1982; Reis, Burns & Renzulli, 1992) is a procedure used for modifying standard curricular content to accommodate advanced learners. Other acceleration techniques should represent essential parts of every school program that strives to respect the individual differences that are clearly evident from classroom performance and/or scores yielded by cognitive ability tests.

### Creative-Productive Giftedness

If scores on IQ tests and other measures of cognitive ability only account for a limited proportion of the common variance with school grades, we can be equally certain that these measures do not tell the whole story when it comes to making predictions about creative-productive giftedness. Before defending this

assertion with some research findings, we briefly review what is meant by this second type of giftedness, the important role that it should play in programming, and, therefore, the reasons we should attempt to assess it in our identification procedures—even if such assessment causes us to look below the top 3 to 5% on the normal curve of IQ scores.

Creative-productive giftedness describes those aspects of human activity and involvement in which a premium is placed on the development of original material and products that are purposefully designed to have an impact on one or more target audiences. Learning situations that are designed to promote creative-productive giftedness emphasize the use and application of information (content) and thinking skills (process) in an integrated, inductive, and real-problem-oriented manner. The role of the student is transformed from that of a learner of prescribed lessons to one in which she or he uses the *modus operandi* of a firsthand inquirer. This approach is quite different from the development of lesson-learning giftedness, which tends to emphasize deductive learning, structured training in the development of thinking processes, and the acquisition, storage, and retrieval of information. In other words, creative-productive giftedness is simply putting one's abilities to work on problems and areas of study that have personal relevance to the student and that can be escalated to appropriately challenging levels of investigative activity. The roles that both students and teachers should play in the pursuit of these problems have been described elsewhere (Renzulli, 1977, 1982), and have been embraced in general education under a variety of concepts such as constructivist theory, authentic learning, discovery learning, problem based learning, and performance assessment.

“Why is creative-productive giftedness important enough for us to question the ‘tidy’ and relatively easy approach that has traditionally been used to select students on the basis of test scores? Why do some people want to rock the boat by challenging a conception of giftedness that can be numerically defined by simply giving a test? The answers to these questions are simple and yet very compelling. A review of the research literature (Renzulli, 1986) tells us that there is much more to identifying human potential than the abilities revealed on traditional tests of intelligence, aptitude, and achievement. Furthermore, history tells us it has been the creative and productive people of the world, the producers rather than consumers of knowledge, the reconstructionists of thought in all areas of human endeavor, who have become recognized as ‘truly gifted’ individuals. History does not remember persons who merely scored well on IQ tests or those who learned their lessons well. The definition of giftedness (See Fig. 1) which characterizes creative productive giftedness and serves as part of the

rationale for the Enrichment Triad Model is the three-ring conception of giftedness (Renzulli, 1978, 1986), in which giftedness: . . . consists of an interaction among three basic clusters being above average general ability, high levels of creativity. Gifted and talented capable of developing this composite set of potentially valuable area of human performance or capable of developing an interaction among these require a variety of educational opportunities and services those not normally through regular instructional programming. (1978, p. 6)

We have advocated that gifted behaviors can be developed through systematic enrichment opportunities described in the Enrichment Triad Model (Renzulli, 1977, 1978, 1988b).

### An Overview of the Enrichment Triad Model

The Enrichment Triad Model was designed to encourage creative productivity on the part of young people by exposing them to various topics, areas of interest, and fields of study, and to further train them to *apply* advanced content, process-training skills, and methodology training to self-selected areas of interest. Accordingly, three types of enrichment are included in the Triad Model (see Fig. 2).

Type I enrichment is designed to expose students to a wide variety of disciplines, topics, occupations, hobbies, persons, places, and events that would not ordinarily be covered in the regular curriculum. In schools that use this model, an enrichment team consisting of parents, teachers, and students often organizes and plans Type I experiences by contacting speakers, arranging micourses, demonstrations, or performances, or by ordering and distributing films, slides, videotapes, or other print or non-print media.

Type II enrichment consists of materials and methods designed to promote the development of thinking and feeling processes. Some Type II training is general, and is usually carried out both in classrooms and in enrichment programs. Training activities include the development of: (1) creative thinking and problem solving, critical thinking, and affective processes; (2) a wide variety of specific learning how-to-learn skills; (3) skills in the appropriate use of advanced-level reference materials; and (4) written, oral, and visual communication skills. Other Type II enrichment is specific, as it cannot be planned in advance and usually involves advanced methodological instruction in an interest area selected by the student. For example, students who become interested in botany after a Type I experience might pursue additional training in this area by doing advanced reading in botany; compiling, planning and carrying out plant experiments; and seeking more advanced methods training if they want to go further.

Type III enrichment involves students who become interested in pursuing a self-selected area and are

willing to commit the time necessary for advanced content acquisition and process training in which they assume the role of a first-hand inquirer. The goals of Type III enrichment include:

- providing opportunities for applying interests, knowledge, creative ideas and task commitment to a self-selected problem or area of study,
- acquiring advanced level understanding of the knowledge (content) and methodology (process) that are used within particular disciplines, artistic areas of expression and interdisciplinary studies,
- developing authentic products that are primarily directed toward bringing about a desired impact upon a specified audience,
- developing self-directed learning skills in the areas of planning, organization, resource utilization, time management, decision making and self-evaluation,
- developing task commitment, self-confidence, and feelings of creative accomplishment.

#### *The Revolving Door Identification Model*

As our experience with Triad Programs grew, our concern about who was being identified to participate in these programs also grew. We became increasingly

concerned about students who were not able to participate in enrichment programs because they did not score in the top 1–3% of the population in achievement or intelligence tests.

Research conducted by Torrance (1962, 1974) had demonstrated that students who were rated highly on creativity measures do well in school and on achievement tests but are often not selected for gifted programs because their scores are often below the cutoff for admission. Some of our own research (Reis, 1981) indicated that when a broader population of students (15–20% of the general population called the ‘talent pool’) were able to participate in Types I and II enrichment experiences, they produced equally good Type III products as the traditional ‘gifted’ students (the top 3–5%). This research produced the rationale for the Revolving Door Identification Model (RDIM) (Renzulli, Reis & Smith, 1981) in which a talent pool of students receives regular enrichment experiences and the opportunity to ‘revolve into’ Type III creative productive experiences. In RDIM, we recommend that students be selected for participation in the talent pool on the basis of multiple criteria that include indices of creativity, because we believe that one of the major purposes of gifted education is to develop creative

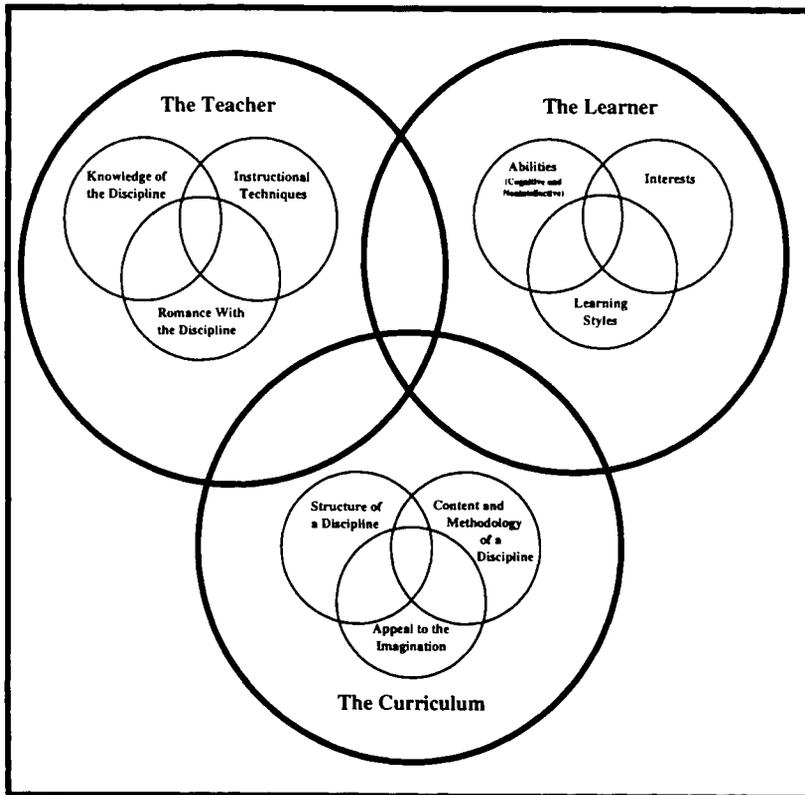

Figure 1. The three-ring conception of giftedness. (Reprinted with permission from Creative Learning Press).

thinking and creative productivity in students. Once identified and placed in the talent pool through the use of test scores, teacher, parent, or self-nomination, and examples of creative potential or productivity, students are observed in classrooms and enrichment experiences for signs of advanced interests, creativity, or task commitment. We have called this part of the process 'action information' and have found it to be an instrumental part of the identification process in assessing students' interest and motivation to become involved in Type III creative productivity. Further support for expanding identification procedures through the use of these approaches has recently been offered by Kirschenbaum (1983) and Kirschenbaum and Siegle (1993) who demonstrated that students who are rated or test high on measures of creativity tend to do well in school and on measures of achievement. The development of the RDIM led to the need for a guide dealing with how all of the components of the previous

Triad and the new RDIM could be implemented and the resulting work was entitled *The Schoolwide Enrichment Model (SEM)* (Renzulli & Reis, 1985, 1997).

*The Schoolwide Enrichment Model (SEM)*

In the SEM, a talent pool of 15–20% of above average ability/high potential students is identified through a variety of measures including: achievement tests, teacher nominations, assessment of potential for creativity and task commitment, as well as alternative pathways of entrance (self-nomination, parent nomination, etc.). High achievement test and IQ test scores automatically include a student in the talent pool, enabling those students who are underachieving in their academic school work to be included.

Once students are identified for the talent pool, they are eligible for several kinds of services; first, interest and learning styles assessments are used with talent

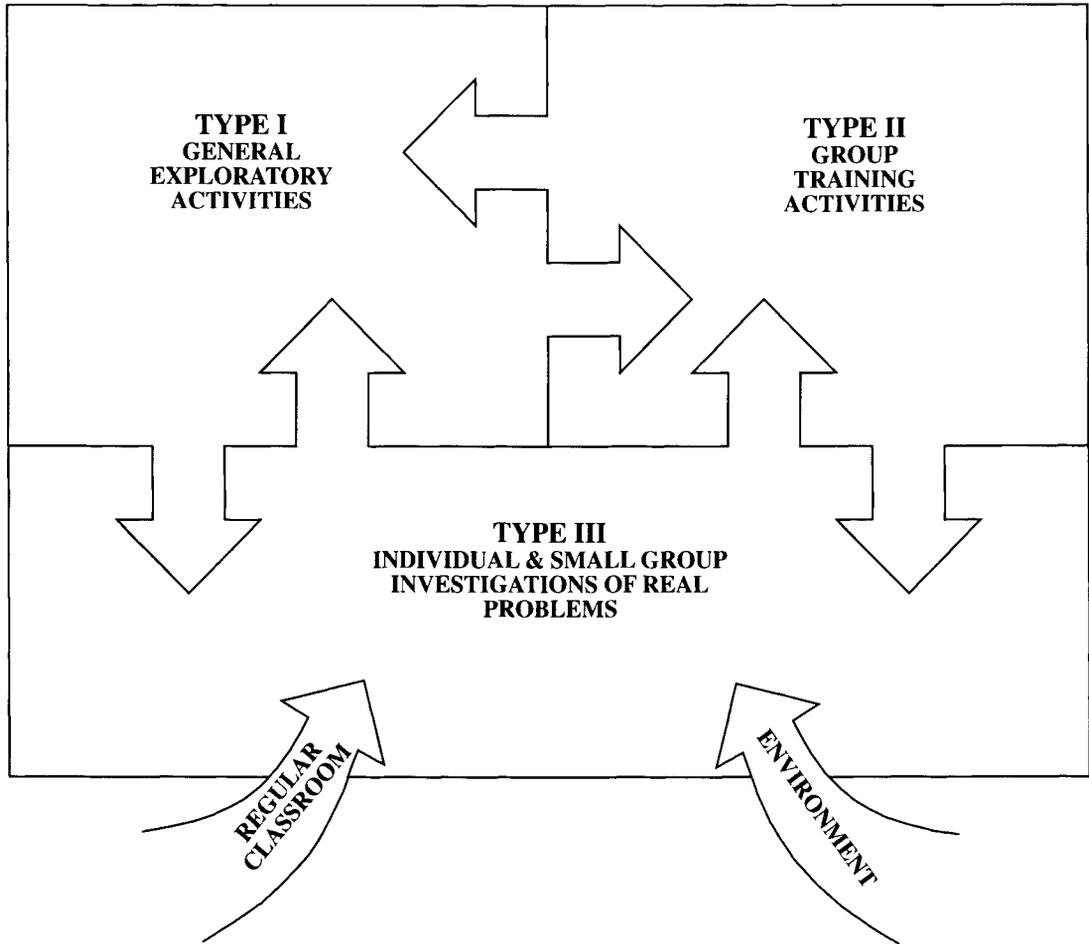

Figure 2. The enrichment triad model.

pool students. Informal and formal methods are used to create or identify students' interests and to encourage students to further develop and pursue these interests in various ways. Learning style preferences which are assessed include: projects, independent study, teaching games, simulations, peer teaching, programmed instruction, lecture, drill and recitation, and discussion. Second, curriculum compacting is provided to all eligible students for whom the regular curriculum is modified by eliminating portions of previously mastered content. This elimination or streamlining of curriculum enables above average students to avoid repetition of previously mastered work and guarantees mastery while simultaneously finding time for more appropriately challenging activities (Reis, Burns & Renzulli, 1992; Renzulli, Smith & Reis, 1982). A form, entitled *The Compactor* (Renzulli & Smith, 1978), is used to document which content areas have been compacted and what alternative work has been substituted. Third, the Enrichment Triad Model, offers three types of enrichment experiences. Type I, II, and III Enrichment are offered to all students; however, Type III enrichment is usually more appropriate for students with higher levels of ability, interest, and task commitment.

Separate studies on the SEM demonstrated its effectiveness in schools with widely differing socioeconomic levels and program organization patterns (Olenchak, 1988; Olenchak & Renzulli, 1989). The SEM has been implemented in several hundred school districts across the country (Burns, 1998) and interest in this approach continues to grow.

### **Newest Directions for the Schoolwide Enrichment Model**

The present reform initiatives in general education have created a more receptive atmosphere for more flexible approaches that challenge all students, and accordingly, the Schoolwide Enrichment Model (SEM) has been expanded to address three major goals that we believe will accommodate the needs of gifted students, and at the same time, provide challenging learning experiences for all students. These goals are:

To maintain and expand a continuum of special services that will challenge students with demonstrated superior performance or the potential for superior performance in any and all aspects of the school and extracurricular program.

To infuse into the general education program a broad range of activities for high-end learning that will: (a) challenge all students to perform at advanced levels, and (b) that will allow teachers to determine which students should be given extended opportunities, resources, and encouragement in particular areas where superior interest and performance are demonstrated.

To preserve and protect the positions of gifted education specialists and any other specialized personnel necessary for carrying out the first two goals.

A graphic representation of the newest adaptation of the model is presented in Fig. 3.

### *School Structures*

#### **The Regular Curriculum**

The regular curriculum consists of everything that is a part of the predetermined goals, schedules, learning outcomes, and delivery systems of the school. The regular curriculum might be traditional, innovative, or in the process of transition, but its predominant feature is that authoritative forces (i.e. policy makers, school councils, textbook adoption committees, state regulators) have determined that the regular curriculum should be the 'centerpiece' of student learning. Application of the SEM influences the regular curriculum in three ways. First, the challenge level of required material is differentiated through processes such as curriculum compacting and textbook content modification procedures. Second, systematic content intensification procedures should be used to replace eliminated content with selected, in-depth learning experiences. Third, types of enrichment recommended in the Enrichment Triad Model (Renzulli, 1977) are integrated selectively into regular curriculum activities. Although our goal in the SEM is to influence rather than replace the regular curriculum, application of certain SEM components and related staff development activities has resulted in substantial changes in both the content and instructional processes of the entire regular curriculum.

#### **The Enrichment Clusters**

The enrichment clusters, one component of the Schoolwide Enrichment Model, are non-graded groups of students who share common interests, and who come together during specially designated time blocks during school to work with an adult who shares their interests and who has some degree of advanced knowledge and expertise in the area. The enrichment clusters usually meet for a block of time weekly during a semester. All students complete an interest inventory developed to assess their interests, and an enrichment team of parents and teachers tally all of the major families of interests. Adults from the faculty, staff, parents, and community are recruited to facilitate enrichment clusters based on these interests, such as creative writing, drawing, sculpting, archeology and other areas. Training is provided to the facilitators who agree to offer the clusters, and a brochure is developed and sent to all parents and students that discusses student interests and select choices of enrichment clusters. A title and description that appeared in a brochure of clusters in a school using the SEM follows:

*Invention Convention*

Are you an inventive thinker? Would you like to be? Brainstorm a problem, try to identify many solutions, and design an invention to solve the problem, as an inventor might give birth to a real invention. Create your invention individually or with a partner under the guidance of Bob Erikson and his students, who work at the Connecticut Science Fair. You may share your final product at the Young Inventors' Fair on March 25th, a statewide daylong celebration of creativity.

Students select their top three choices for the clusters and scheduling is completed to place all children into their first, or in some cases, second choice. Like extra-curricular activities and programs such as 4-H and Junior Achievement, the main rationale for participa-

tion in one or more clusters is that *students and teachers want to be there*. All teachers (including music, art, physical education, etc.) are involved in teaching the clusters; and their involvement in any particular cluster is based on the same type of interest assessment that is used for students in selecting clusters of choice.

The model for learning used with enrichment clusters is based on an inductive approach to solving real-world problems through the development of authentic products and services. Unlike traditional, didactic modes of teaching, this approach, known as enrichment learning and teaching (described fully in a later section), uses the Enrichment Triad Model to create a learning situation that involves the use of methodology, develops higher order thinking skills,

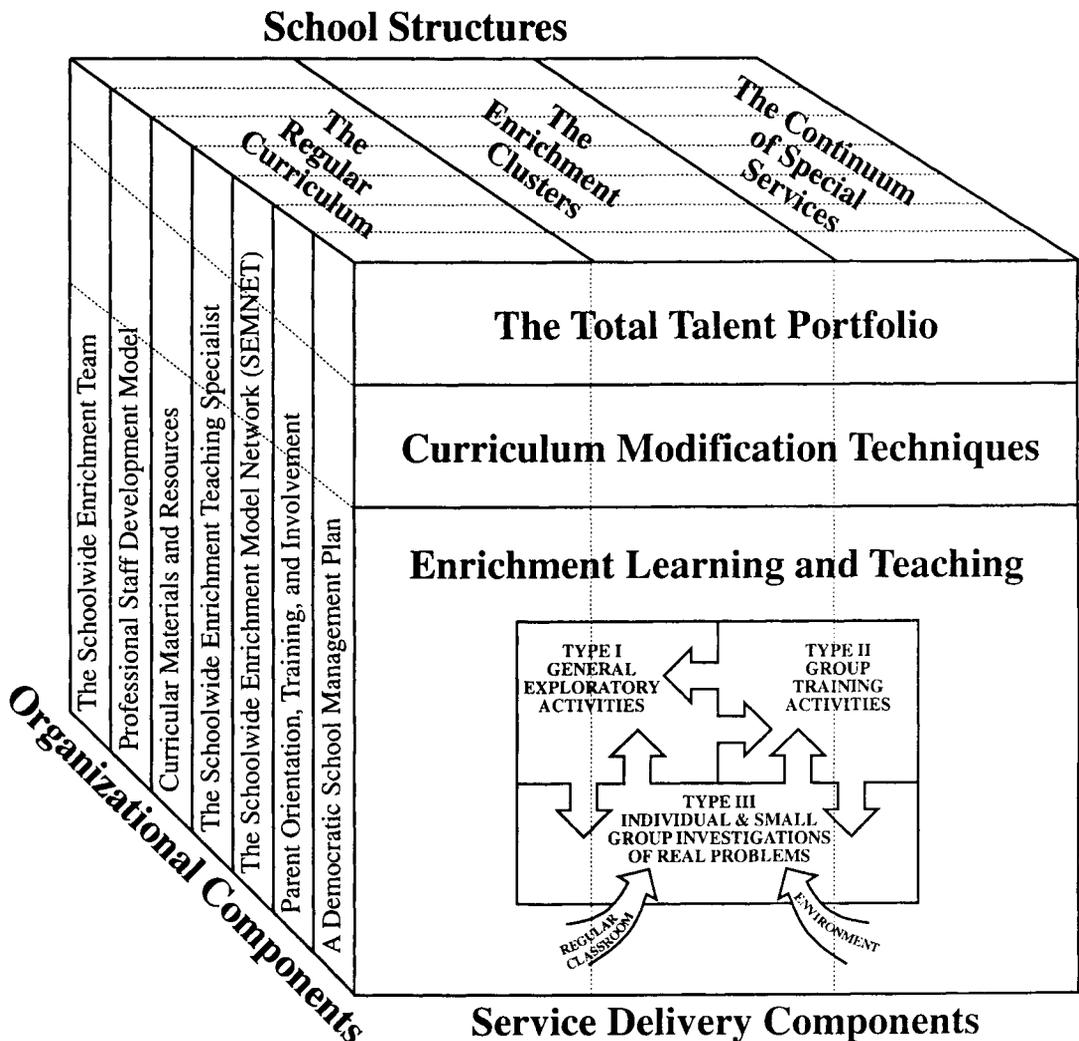

Figure 3. The schoolwide enrichment model.

and authentically applies these skills in creative and productive situations. Enrichment clusters promote cooperativeness within the context of real-world problem solving, and they also provide superlative opportunities for promoting self-concept. "A major assumption underlying the use of enrichment clusters is that *every child is special if we create conditions in which that child can be a specialist within a specialty group*" (Renzulli, 1994, p. 70).

Enrichment clusters are organized around various characteristics of differentiated programming for gifted students on which the Enrichment Triad Model (Renzulli, 1977) was originally based, including the use of major disciplines, interdisciplinary themes, or cross-disciplinary topics (e.g. a theatrical/television production group that includes actors, writers, technical specialists, costume designers). The clusters are modeled after the ways in which knowledge utilization, thinking skills, and interpersonal relations take place in the real world. Thus, all work is directed toward the production of a product or service. No lesson plans or unit plans are created in advance by the cluster facilitator; rather, direction is provided by three key questions addressed in the cluster by the facilitator and the students:

- (1) What do people with an interest in this area (e.g. film making) do?
- (2) What knowledge, materials, and other resources do they need to do it in an excellent and authentic way?
- (3) In what ways can the product or service be used to have an impact on an intended audience?

Enrichment clusters incorporate the use of advanced content, providing students with information about particular fields of knowledge, such as the structure of a field as well as the basic principles and the functional concepts in a field (Ward, 1960). Ward defined functional concepts as the intellectual instruments or tools with which a subject specialist works, such as the vocabulary of a field and the vehicles by which persons within the field communicate with one another. The methodology used within a field is also considered advanced content by Renzulli (1988a), involving the use of knowledge of the structures and tools of fields, as well as knowledge about the methodology of particular fields. This knowledge about the methodologies of fields exists both for the sake of increased knowledge acquisition, and also for the utility of that know-how as applied to the development of products, even when such products are considered advanced in a relative sense (i.e. age, grade, and background considerations).

The enrichment clusters are not intended to be the total program for talent development in a school, or to replace existing programs for talented youth. Rather, they are one vehicle for stimulating interests and developing talent potentials across the entire school

population. They are also vehicles for staff development in that they provide teachers an opportunity to participate in enrichment teaching, and subsequently to analyze and compare this type of teaching with traditional methods of instruction. In this regard the model promotes a spill-over effect by encouraging teachers to become better talent scouts and talent developers, and to apply enrichment techniques to regular classroom situations.

### The Continuum of Special Services

A broad range of special services is the third school structure targeted by the model; a diagram representing these services is presented in Fig. 4. Although the enrichment clusters and the SEM-based modifications of the regular curriculum provide a broad range of services to meet individual needs, a program for total talent development still requires supplementary services that challenge young people who are capable of working at the highest levels of their special interest and ability areas. These services, which cannot ordinarily be provided in enrichment clusters or the regular curriculum, typically include: individual or small group counseling, direct assistance in facilitating advanced level work, arranging for mentorships with faculty members or community persons, and making other types of connections between students, their families, and out-of-school persons, resources, and agencies.

Direct assistance also involves setting up and promoting student, faculty and parental involvement in special programs such as Future Problem Solving, Odyssey of the Mind, the Model United Nations program, and state and national essay, mathematics, art, and history contests. Another type of direct assistance consists of arranging out-of-school involvement for individual students in summer programs, on-campus courses, special schools, theatrical groups, scientific expeditions, and apprenticeships at places where advanced level learning opportunities are available. Provision of these services is one of the responsibilities of the schoolwide enrichment teaching specialist or an enrichment team of teachers and parents who work together to provide options for advanced learning. A schoolwide enrichment teaching specialist in Barrington, Rhode Island, estimates she spends two days a week in a resource capacity to the faculties of two schools, and three days providing direct services to students.

### Service Delivery Components

#### The Total Talent Portfolio

The Schoolwide Enrichment Model targets specific learning characteristics that can serve as a basis for talent development. Our approach to targeting learning characteristics uses both traditional and performance-based assessment to compile information about three dimensions of the learner—abilities, interests, and

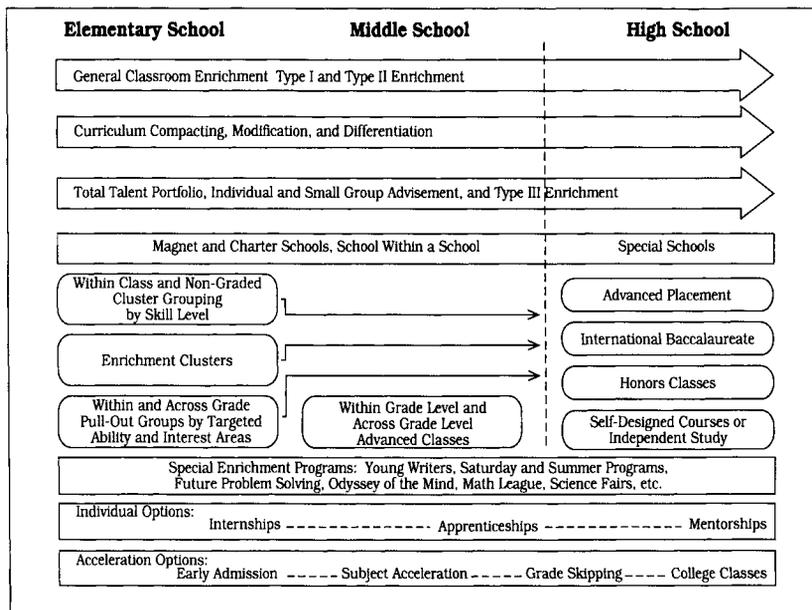

Figure 4. The continuum of services for total talent development.

learning styles. This information, which focuses on strengths rather than deficits, is compiled in a management form called the 'Total Talent Portfolio' (see Fig. 5) which is used to make decisions about talent development opportunities in regular classes, enrichment clusters, and in the continuum of special services. The major purposes of the Total Talent Portfolio are:

- (1) To *collect* several different types of information that portray a student's strength areas, and to regularly update this information.
- (2) To *classify* this information into the general categories of abilities, interests, and learning styles and related markers of successful learning such as organizational skills, content area preferences, personal and social skills, preferences for creative productivity, and learning-how-to-learn skills.
- (3) To periodically *review and analyze* the information in order to make purposeful decisions about providing opportunities for enrichment experiences in the regular classroom, the enrichment clusters, and the continuum of special services.
- (4) To *negotiate* various acceleration and enrichment learning options and opportunities between teacher and student through participation in a shared decision making process.
- (5) To *use the information* as a vehicle for educational, personal, and career counseling and for communicating with parents about the school's talent development opportunities and their child's involvement in them.

This expanded approach to identifying talent potentials is essential if we are to make genuine efforts to include more under-represented students in a plan for *total* talent development. This approach is also consistent with the more flexible conception of *developing* gifts and talents that has been a cornerstone of our work and our concerns for promoting more equity in special programs.

#### Curriculum Modification Techniques

The second service delivery component of the SEM is a series of curriculum modification techniques designed to: (1) adjust levels of required learning so that all students are challenged, (2) increase the number of in-depth learning experiences, and (3) introduce various types of enrichment into regular curricular experiences. The procedures that are used to carry out curriculum modification are curriculum compacting, textbook analysis and surgical removal of repetitious material from textbooks, and a planned approach for introducing greater depth into regular curricular material. Due to space restrictions, curriculum compacting is described in depth here and other modification techniques are described in detail in other publications (see, for example, Renzulli, 1994; Reis et al., 1993).

#### How to Use the Compacting Process

*Defining goals and outcomes.* The first of three phases of the compacting process consists of defining the goals and outcomes of a given unit or segment of

instruction. This information is readily available in most subjects because specific goals and outcomes can usually be found in teachers' manuals, curriculum guides, scope-and-sequence charts, and some of the new curricular frameworks that are emerging in connection with outcome based education models. Teachers should examine these objectives to determine which represent the acquisition of new content or thinking skills as opposed to reviews or practice of material that has previously been taught. The scope and sequence charts prepared by publishers, or a simple comparison of the table of contents of a basal series will provide a quick overview of new vs. repeated material. A major goal of this phase of the compacting process is to help teachers make individual programming decisions; a larger professional development goal is to help teachers be better analysts of the material they are teaching and better consumers of textbooks and prescribed curricular material.

*Identifying students for compacting.* The second phase of curriculum compacting is identifying students who have already mastered the objectives or outcomes of a unit or segment of instruction that is about to be taught. This first step of this phase consists of estimating

which students have the potential to master new material at a faster than normal pace; knowing one's students is, of course, the best way to begin the assessment process. Scores on previous tests, completed assignments, and classroom participation are the best ways of identifying highly likely candidates for compacting. Standardized achievement tests can serve as a good general screen for this step because they allow us to list the names of all students who are scoring one or more years above grade level in particular subject areas.

Being a candidate for compacting does not necessarily mean that a student knows the material under consideration. Therefore, the second step of identifying candidates consists of finding or developing appropriate tests or other assessment techniques that can be used to evaluate specific learning outcomes. Unit pretests, or end-of-unit tests that can be administered as pretests are readymade for this task, especially when it comes to the assessment of basic skills. An analysis of pretest results enables the teacher to document proficiency in specific skills, and to select instructional activities or practice material necessary to bring the student up to a high level on any skill that may need some additional reinforcement.

Figure 5. The total talent portfolio.

The process is slightly modified for compacting content areas that are not as easily assessed as basic skills, and for students who have not mastered the material, but are judged to be candidates for more rapid coverage. First, students should have a thorough understanding of the goals and procedures of compacting, including the nature of the replacement process. A given segment of material should be discussed with the student (e.g. a unit that includes a series of chapters in a social studies text), and the procedures for verifying mastery at a high level should be specified. These procedures might consist of answering questions based on the chapters, writing an essay, or taking the standard end-of-unit test. The amount of time for completion of the unit should be specified, and procedures such as periodic progress reports or log entries for teacher review should be agreed upon. Of course, an examination of potential acceleration and/or enrichment replacement activities should be a part of this discussion.

Another alternative is to assess or pretest all students in a class when a new unit or topic is introduced; although this may seem like more work for the teacher, it provides the opportunity for all students to demonstrate their strengths or previous mastery in a given area. Using a matrix of learning objectives, teachers can fill in test results and establish small, flexible, and temporary groups for skill instruction and replacement activities.

*Providing acceleration and enrichment options.* The final phase of the compacting process can be one of the most exciting aspects of teaching because it is based on cooperative decision making and creativity on the parts of both teachers and students. Efforts can be made to gather enrichment materials from classroom teachers, librarians, media specialists, and content area or gifted education specialists. These materials may include self-directed learning activities, instructional materials that focus on particular thinking skills, and a variety of individual and group project oriented activities that are designed to promote hands-on research and investigative skills. The time made available through compacting provides opportunities for exciting learning experiences such as small group, special topic seminars that might be directed by students or community resource persons, community based apprenticeships or opportunities to work with a mentor, peer tutoring situations, involvement in community service activities, and opportunities to rotate through a series of self-selected mini-courses. The time saved through curriculum compacting can be used by the teacher to provide a variety of enrichment or acceleration opportunities for the student.

Enrichment strategies might include a variety of Type I, II, or III or a number of options included on the continuum of services. Acceleration might include the use of material from the next unit or chapter, the use of

the next chronological grade level textbook or the completion of even more advanced work. Alternative activities should reflect an appropriate level of challenge and rigor that is commensurate with the student's abilities and interests.

Decisions about which replacement activities to use are always guided by factors such as time, space, and the availability of resource persons and materials. Although practical concerns must be considered, the ultimate criteria for replacement activities should be the degree to which they increase academic challenge and the extent to which they meet individual needs. Great care should be taken to select activities and experiences that represent individual strengths and interests rather than the assignment of more-of-the-same worksheets or randomly selected kits, games, and puzzles! This aspect of the compacting process should also be viewed as a creative opportunity for an entire faculty to work cooperatively to organize and institute a broad array of enrichment experiences. A favorite mini-course that a faculty member has always wanted to teach, or serving as a mentor to one or two students who are extremely invested in a teacher's beloved topic are just a few of the ways that replacement activities can add excitement to the teachers' part in this process as well as the obvious benefits for students. We have also observed another interesting occurrence that has resulted from the availability of curriculum compacting. When some previously bright but underachieving students realized that they could both economize on regularly assigned material and 'earn time' to pursue self-selected interests, their motivation to complete regular assignments increased; as one student put it, "Everyone understands a good deal!"

The best way to get an overview of the curriculum compacting process is to examine an actual example of how the management form that guides this process is used. This form, 'The Compactor', presented in Fig. 6, serves as both an organizational and record keeping tool. Teachers should fill out one form per student, or one form for a group of students with similar curricular strengths. Completed Compactors should be kept in students' academic files, and updated on a regular basis. The form can also be used for small groups of students who are working at approximately the same level (e.g. a reading or maths group). The Compactor is divided into three sections:

- The first column should include information on learning objectives and student strengths in those areas. Teachers should list the objectives for a particular unit of study, followed by data on students' proficiency in those objectives, including test scores, behavioral profiles and past academic records.
- In the second column, teachers should detail the pretest vehicles they select, along with test results. The pretest instruments can be formal measures, such as pencil and paper tests, or informal measures,

such as performance assessments based on observations of class participation and written assignments.

Specificity is extremely important; recording an overall score of 85% on ten objectives, for example, sheds little light on what portion of the material can be compacted, since students might show limited mastery of some objectives and high levels of mastery on others.

- Column three is used to record information about acceleration or enrichment options; in determining these options, teachers must be fully aware of students' individual interests and learning styles. We should never replace compacted regular curriculum work with harder, more advanced material that is solely determined by the teacher; instead, students interests should be taken into account. If for example, a student loves working on science fair projects, that option may be used to replace material that has been compacted from the regular curriculum. We should also be careful to help monitor the challenge level of the material that is being substituted. We want students to understand the nature of

effort and challenge and we should ensure that students are not simply replacing the compacted material with basic reading or work that is not advanced.

*Rosa: A Case Study in Curriculum Compacting*

Rosa is a fifth grader in a self-contained heterogeneous classroom; her school is located in a lower socio-economic urban school district. While Rosa's reading and language scores range between four or five years above grade level, most of her 29 classmates are reading one to two years below grade level. This presented Rosa's teacher with a common problem: what was the best way to instruct Rosa? He agreed to compact her curriculum. Taking the easiest approach possible, he administered all of the appropriate unit tests for the grade level in the Basal Language Arts program, and excused Rosa from completing the activities and worksheets in the units where she showed proficiency (80% and above). When Rosa missed one or two questions, the teacher checked for trends in those items and provided instruction and practice materials to ensure concept mastery.

## INDIVIDUAL EDUCATIONAL PROGRAMMING GUIDE

Figure 6. The compactor.

Rosa usually took part in language arts lessons one or two days a week; the balance of the time she spent with alternative projects, some of which she selected. This strategy spared Rosa up to six or eight hours a week with language arts skills that were simply beneath her level. She joined the class instruction only when her pretests indicated she had not fully acquired the skills or to take part in a discussion that her teacher thought she would enjoy. In the time saved through compacting, Rosa engaged in a number of enrichment activities. First, she spent as many as five hours a week in a resource room for high ability students. This time was usually scheduled during her language arts class, benefiting both Rosa and her teacher, since he didn't have to search for all of the enrichment options himself. The best part of the process for Rosa was she didn't have make-up regular classroom assignments because she was not missing essential work.

Rosa also visited a regional science center with other students who had expressed a high interest and aptitude for science. Science was a second strength area for Rosa, and based on the results of her *Interest-A-Lyzer*, a decision was made for Rosa to proceed with a science fair project on growing plants under various conditions. Rosa's Compactor, which covered an entire semester, was updated in January. Her teacher remarked that compacting her curriculum had actually saved him time—time he would have spent correcting papers needlessly assigned! The value of compacting for Rosa convinced him that he should continue the process. The Compactor was also used as a vehicle for explaining to Rosa's parents how specific modifications were being made to accommodate her advanced language arts achievement level and her interest in science. A copy of The Compactor was also passed on to Rosa's sixth grade teacher, and a conference between the fifth and sixth grade teachers and the resource teacher helped to ensure continuity in dealing with Rosa's special needs.

The many changes that are taking place in our schools require all educators to examine a broad range of techniques for providing equitably for *all* students. Curriculum compacting is one such process. It is not tied to a specific content area or grade level, nor is it aligned with a particular approach to school or curricular reform. Rather, the process is adaptable to any school configuration or curricular framework, and it is flexible enough to be used within the context of rapidly changing approaches to general education. The research study described above, and practical experience gained through several years of field testing and refining the compacting process have demonstrated that many positive benefits can result from this process for both students and teachers.

#### Enrichment Learning and Teaching

The third service delivery component of the SEM, which is based on the Enrichment Triad Model, is

enrichment learning and teaching which has roots in the ideas of a small but influential number of philosophers, theorists, and researchers such as Jean Piaget (1975), Jerome Bruner (1960, 1966), and John Dewey (1913, 1916). The work of these theorists coupled with our own research and program development activities, has given rise to the concept we call enrichment learning and teaching. The best way to define this concept is in terms of the following four principles:

- (1) Each learner is unique, and therefore, all learning experiences must be examined in ways that take into account the abilities, interests, and learning styles of the individual.
- (2) Learning is more effective when students enjoy what they are doing, and therefore, learning experiences should be constructed and assessed with as much concern for enjoyment as for other goals.
- (3) Learning is more meaningful and enjoyable when content (i.e. knowledge) and process (i.e. thinking skills, methods of inquiry) are learned within the context of a real and present problem; and therefore, attention should be given to opportunities to personalize student choice in problem selection, the relevance of the problem for individual students at the time the problem is being addressed, and authentic strategies for addressing the problem.
- (4) Some formal instruction may be used in enrichment learning and teaching, but a major goal of this approach to learning is to enhance knowledge and thinking skill acquisition that is gained through formal instruction with applications of knowledge and skills that result from students' own construction of meaning (Renzulli, 1994, p. 204).

The ultimate goal of learning that is guided by these principles is to replace dependent and passive learning with independence and engaged learning. Although all but the most conservative educators will agree with these principles, much controversy exists about how these (or similar) principles might be applied in everyday school situations. A danger also exists that these principles might be viewed as yet another idealized list of glittering generalities that cannot be manifested easily in schools that are entrenched in the deductive model of learning; developing a school program based on these principles is not an easy task. Over the years, however, we have achieved success by gaining faculty, administrative, and parental consensus on a small number of easy-to-understand concepts and related services, and by providing resources and training related to each concept and service delivery procedure. Numerous research studies and field tests in schools with widely varying demographics have been carried out (Renzulli & Reis, 1994). These studies and field tests provided opportunities for the development

of large amounts of practical know-how that are readily available for schools that would like to implement the SEM. They also have shown that the SEM can be implemented in a wide variety of settings and used with various populations of students including high ability students with learning disabilities and high ability students who underachieve in school.

# Instructional Psychology and the Gifted

Hans Gruber<sup>1</sup> and Heinz Mandl<sup>2</sup>

## 1. Fostering Excellence: The Role of Dispositions and Practice

Instructional psychology aims at fostering learning or even the growth of 'excellence'—a term we are going to use synonymously with the term 'high-level performance'. There are two bodies of research dealing with this topic that are only loosely connected: research on 'giftedness'—we are going to use this term synonymously with the term 'high ability'—(Sternberg & Davidson, 1986; Heller, Mönks & Passow, 1993), and research on 'expertise' (Ericsson & Smith, 1991; Ericsson, 1996; Gruber & Ziegler, 1996). Both are taking different theoretical perspectives on the same educational processes, and they frequently argue that the respective other research is doing the wrong thing. If the narrow viewpoints are left aside it can be recognized that both directions contribute to the same phenomena, and that both are dependent on each other, because the complex goal of fostering the development of excellence requires both favourable individual dispositions and intensive deliberate practice (Ericsson, Krampe & Tesch-Römer, 1993) over a long period. Analyses of expert information processing and of processes of the learning of the gifted are necessary pre-conditions of instructional fostering of the development of excellence, if instruction is aimed to go beyond the pure placement of subjects in different pre-existing learning environments. The notion of situated learning gives opportunity to adequately foster any learners in demanding learning environments by making use both of the evidence from research on expertise and on giftedness. Of course, the idea of integrating research on giftedness and research on expertise is not entirely new, but has only rarely been discussed. Some approaches exist in the U.S. as well as in Europe (Sternberg, 1990b; Gruber & Mandl, 1992; Waldmann, 1996; Perleth, 1997), which is reflected in this book's contributions, and parts of the discussion can be found in the nurture-or-nature controversy which re-inflamed after the publication of Herrnstein and Murray's (1994)

theses on differences in intelligence and their instructional consequences (Neisser et al., 1996; Devlin, Fienberg, Resnick & Roeder, 1997). Resnick (1996) convincingly argued that nature and nurture factors have to be integrated, and that within situated learning theories, promising instructional approaches were developed for fostering the acquisition of excellence. These approaches basically view learning as tuning of prepared structures and, therefore, include both dispositional factors and practice factors.

This chapter consists of six parts. Sections 2 and 3 provide an overview of research on conditions of the development of high-level performance. The main outcomes from traditional research on giftedness (section 2) and from traditional research on expertise (section 3) are reported; reasons for the empirical lack of substantial correlations between both are then discussed (section 4). Their interaction during the acquisition of excellence despite low correlations is then described (section 5). Theories of the acquisition of expertise and high abilities are discussed in order to explain and model changes in the relation between giftedness and instructional support; at the core, it is argued that dispositions influence information processing. Local instructional efforts try to foster singular individual capabilities for reaching better performance. On the other hand, individual learning processes are embedded in complex social contexts. Approaches for complex learning based on situated cognition models integrate these perspectives and provide guidelines for the design of learning environments that are helpful for acquiring excellence, including adequate fostering of the gifted. In these approaches, authenticity and complexity of learning environments are considered crucial (section 6).

## 2. Traditional Research on Giftedness: Focus on Dispositions

The assumption that some people are more intellectually gifted than others is an attractive one for instructional psychology: The task of fostering excellence is much facilitated if high-level performance can

<sup>1</sup> University of Regensburg, Germany.

<sup>2</sup> University of Munich, Germany.

E-mail: mandl@edupsy.uni-muenchen.de

be reliably predicted by a set of abilities that are stable over time and that can be assessed by (e.g.) IQ tests. Identifying the gifted then is a major task of instructional psychology, but not an easy one, because unanimously agreed upon definitions do not exist.

This handbook shows that a number of different conceptions of giftedness have been elaborated in various research programs. Part I of the handbook deals with changing conceptions on giftedness and talent and thus should prevent argumentative oversimplifications. Traditional research on giftedness focused on innate dispositions. Conceptions that consider high ability as an innate disposition stress the 'nature' component of human development and view giftedness as rather stable property of (some) individuals. The most important and most widely discussed dispositional factor of this kind is 'general intelligence' ('g'; Jensen, 1998), and much effort in assessing giftedness and in identifying gifted persons is closely tied to research on 'g'. Of course, nobody would deny that environmental factors also play an important role in the emergence of high-level performance, but the consequences of the focus on dispositions for instructional psychology are substantial. Giftedness conceived as a relatively stable property predicts the potential of development and limits the effects of what can be achieved by instructional efforts. In terms of the equation 'Nature + Nurture = Performance', traditional approaches to research on giftedness tend to neglect the nurture part. In section 3, we will discuss research that prefers the opposite model: in research on expertise some have argued that dispositional factors play a negligible role in the acquisition of high-level performance (e.g. Ericsson & Charness, 1994; Howe, Davidson & Sloboda, 1998). Mixed models that conceive giftedness via (high) performance resulting from the convergence of positive dispositions and positive environmental factors put their focus on the interaction of both components (Holling & Kanning, 1999). They have to struggle with the argument that environmental variables can frequently clearly be operationalized and experimentally varied whereas dispositions cannot.

Of course, 'g' is not the only feature characteristic of the gifted (Van Tassel-Baska, 1998). However, many of the observable correlates of intellectual giftedness are related to constructs measured by IQ tests: excellence in logical thinking; quick comprehension of abstract thoughts; correct inductive reasoning; understanding of complex relations; quick and correct learning; flexible use of an elaborated vocabulary; outstanding memory, etc. (Heller & Hany, 1996). The ascribed importance of 'g' is to a substantial degree a result of the research method used. Ceci and Ruiz (1992) argued that a psychometric approach, which aims at identifying the most important components of mental performance by computing a Principal Component Analysis, more or less automatically results in 'g' as the factor explaining the largest portion of variance. It has been argued that

factorial theories are theories about the structure of correlation matrices of abilities tests, but not theories of the human mind. Approaches using a research paradigm different from factor analysis come to different conclusions. For example, models using the analysis of cognitive processes stress that differences in cognitive performance result from differences in (the dispositions of) information processing speed (Kail & Salthouse, 1994; Schweizer, 1998) or in working memory capacity (Kyllonen & Christal, 1990).

Non-intellectual abilities have frequently have been included in models of giftedness, but have not received as much attention, because they do not explain as much variance as 'g'. Their role for high-level performance cannot as clearly be identified as with working memory or information processing speed. One notable exception is the concept of emotional intelligence (Goleman, 1995, 1998; Salovey & Mayer, 1997), which recently received wide public attention. Descriptive analyses of successful people show that they are not just good at their jobs, but they also tend to be smart, resilient and optimistic. To be successful at work, the ability is needed to restrain negative feelings (e.g. self-doubt) and to focus on the positive (e.g. confidence). From an instructional point of view, such kinds of emotional intelligence are attractive, because they can be built and learned, whereas IQ is relatively fixed; however, little empirical research in this direction exists.

Correlational studies revealed relations between intellectual components of giftedness and achievement motivation (Dai, Moon & Feldhusen, 1998): gifted students have strong motivation, they show higher academic self-efficacy than others, they surpass others in prediction accuracy and in precision of estimation of their own ability. Consequently, multifactorial theoretical models of giftedness have been developed that include non-intellectual components (cf. Fels, 1999). Many of these models are described in other chapters of this handbook. It is important to stress the theoretical argument that giftedness includes not only innate intellectual abilities. Be it Vygotsky's 'Dynamic Theory of Giftedness' (cf. Babaeva, 1999) with its focus on the social determination of development and defining gifted performance as overcoming emerging barriers; or be it Renzulli's (1986) 'Three-Ring Conception' including task commitment and creativity as parts of giftedness, or be it Mönks' (1992) 'Triadic Interdependence Model': all stress the dispositional nature of giftedness, but hypothesize the necessity of intensive instructional efforts in order to foster excellence. IQ in these models reflects only a particular type of cognition (namely academic-verbal performance) rather than the general aptitude for complex thinking. Sternberg (1990a) argued that metaphors of mind determine the nature of theories of intelligence, and the biological 'look inward' metaphor of theories of intelligence stressing 'g' is one kind of description, but not the only one. (For an outline of his preferred model

of intelligence and instructional implications see section 5 of this chapter.) Simonton (1999) convergently argued that complex models of innate giftedness and talent are necessary. He described talent "as a multidimensional and multiplicative developmental process. This point is elaborated in the form of a 2-part emergent-epigenetic model" (p. 435). Both the analysis of individual differences in dispositional traits that facilitate the manifestation of expert performance and the development of innate components during life have to be considered.

In different multi-dimensional theories of giftedness, the relationship between person-internal and environmental factors is conceived quite differently. Gallagher and Courtright (1986) therefore classified theories as either 'psychological' (e.g. Renzulli, 1986) or as 'educational' (e.g. Tannenbaum, 1986). This dualism does not imply that instructional psychology is considered relevant only in the latter group, because special needs of the gifted have to be met even if the relative importance of environmental factors is conceptualized as small. Many chapters of Part IV of this handbook address instructional tasks of education of the gifted, as the needs for a challenging education, for 'true peers', for adult empathy, for responsive parenting or—in our context most important—for special instruction. Heller (1999a, b) described education of the gifted as the fit between individual cognitive and motivational pre-conditions of the learning process and the instructional situation (cf. Feger & Prado, 1998). Such education can follow the strategies of grouping (forming groups homogeneous in achievement), of acceleration of instruction (changing the speed of instruction; cf. Southern, Jones & Stanley, this volume), or of enrichment (changing the quality of contents of instruction; cf. Renzulli & Reis, this volume). In terms of school achievement, research provided more support for acceleration programs than for enrichment programs, but the particular outcomes of enrichment programs perhaps are not in the scope of school achievement measures. New developments in instructional psychology (see section 6 of this chapter) led into the design of learning environments that seek to avoid the problem of inert knowledge and that facilitate the acquisition of complex, applicable knowledge and skills. Such efforts resemble enrichment programs much more than acceleration programs.

### 3. Traditional Research on Expertise: Focus on Practice

The second research stream that has to be dealt with when discussing instructional efforts for fostering excellence is research on expertise. Some agents in this stream strongly argue that giftedness or talent are not at all important and that high-level performance is predominantly acquired rather than inherited (Ericsson & Charness, 1994). This implies that instruction in whatever manifestation is believed to impose certain

effects on acquisition of expertise. "The necessity for innate talents has been questioned and recently collected evidence shows that superior performance reflects primarily acquired skills and other attributes attained as the result of extended training and practice." (Ericsson, 1998, p. 75) Undoubtedly, no excellent person in any complex skill can be found that did not practice within this domain for a long period. As a consequence, giftedness (if it exists at all) and practice inevitably are confounded and can hardly be analyzed separately. (Simonton, 1999, p. 435, referred to a quotation that is ascribed to the famous violin virtuoso Sarasate when called a genius: "A genius! For thirty-seven years I've practiced fourteen hours a day, and now they call me a genius!") Effortful—and often not enjoyable—commitment in training activities over a long period of time that solely has the purpose of improving the performance is an important characteristic of the process of acquisition of excellence; Ericsson et al. (1993) described this kind of work as 'deliberate practice'. However, some components of the acquisition of excellence can preferably be interpreted in terms of giftedness, whereas others clearly underlie mechanisms of extended practice. Ericsson (1998) admitted limits of the deliberate practice approach: "However, the motivational factors that sustain the expert performers' commitment toward gradual effortful improvement for extended periods of time still remain mostly unexplored." (p. 96)

Empirical studies from research on expertise are most frequently based on the contrastive approach (Voss, Fincher-Kiefer, Greene & Post, 1986). By cross-sectionally comparing experts with novices, the 'nature of expertise' (Chi, Glaser & Farr, 1988) can comprehensively be revealed. The primary aim of expert-novice studies is to identify contrasting characteristics, both qualitative and quantitative, of subjects with various levels of knowledge and skills in a certain domain, and thus to establish theories by incorporating the variables so isolated to account for the observed differences in their performance in that domain. The practical concern is to draw some instructional implications from these studies for training novices into experts (Law, 1995). One of the descriptive findings is that experts in any complex domain have been active within this domain for many years so that the argument is supported that extensive practice is the most important explaining variable for reaching high-level performance. Most researchers on expertise (more or less implicitly) assume that extensive practice is not only a necessary, but a sufficient condition for the acquisition of expertise. As a consequence, individual differences in dispositions are regarded as unimportant, and findings of zero-correlations between, for example, level of expertise and intelligence seem to support this interpretation. (Section 4 is devoted to arguments that show that this conclusion is not necessarily valid.) The instructional consequence is that experts in an earlier

stage of their career did not differ from novices at that particular stage, so that the cross-sectional comparison between both allows longitudinal interpretation. The finding that experts possess much more domain knowledge than novices then leads to the interpretation that fostering excellence is simply adding knowledge. In view of the fact that experts organize knowledge and approach problem-solving differently from novices, the goal of instruction from a cognitive perspective, then, seems to be to replicate the knowledge structure and cognitive processes of the expert in the mind of the learner (Glaser, 1989). We will return to that argument later, but will first review further basic findings of research on expertise.

Among the most interesting results of research on expertise is the evidence for experts' excellent memory for domain-specific material. A chess master is able to correctly remember a chess position (containing more than 20 pieces) after being presented with it for only a few seconds (De Groot, 1965). In contrast, novices remember no more than about seven pieces (effect size in contrastive studies often has scores  $d > 2!$ ). Such dramatic differences in memory performance cannot be explained by differences in memory dispositions as could be suspected: in control tasks (e.g. digit-span), no differences between experts and novices can be traced (Schneider, Gruber, Gold & Opwis, 1993). This implies that it is domain-specific practice that contributes to differences in memory performance. The concept of 'pattern recognition' (Chase & Simon, 1973; Gobet & Simon, 1996) was developed to explain (and simulate) the contrastive differences; it is plainly based on accumulation of knowledge units (chunks) through practice. Experts' ability to analyze newly presented domain-specific information very quickly and to recognize semantically relevant patterns is based on a large knowledge base they already possess. It was shown that the integration of perception and knowledge in memory performance can be explained by (1) chunking processes for semantical association of information units (De Groot & Gobet, 1996), and by (2) building up a highly organized memory structure for fast storing and recalling of domain knowledge (Ericsson, 1985).

The related cognitive processes do not depend on specific dispositions so that it has been argued that everyone could become expert in any domain, given only extended practice within that domain. Ericsson and Crutcher (1990) speak of about ten years needed for the acquisition of expertise in any complex domain. Evidence exists across many domains that experts have extensive knowledge at their disposal, and that they intensively practiced over many years. Additionally, given the fact that experts per definition excel in domain-specific performance, the conclusion can be drawn that the construction of a large knowledge base is sufficient for the acquisition of expertise. However, the relationship between high-level performance on the

one hand and memory skill and knowledge structure on the other is correlative in nature so that causal interpretations remain speculative.

Rather, there exists evidence that the availability of a large knowledge base is not necessarily connected with high-level performance, at least as far as declarative knowledge is concerned. The problem of 'inert knowledge' has emerged as one of the most urgent problems for instructional psychology in the last decades (Bransford, Goldman & Vye, 1991; Renkl, Mandl & Gruber, 1996). Besides knowledge accumulation a careful design of learning environments is important that gives opportunity to make 'right' experiences and to apply the knowledge-to-be-learned in relevant situations (Prerau, Adler & Gunderson, 1992).

The problem of inert knowledge has not yet received much attention within research on expertise, despite the fact that some authors have illuminated 'costs of expertise' (Arkes & Freedman, 1984). One of the reasons is that many studies have been performed in domains that can be described as well-defined (e.g., programming), in which the problem is not as urgent as in others. In such domains, the problems usually to be solved are clearly defined; there exist optimal solutions, the veridicality of knowledge is rarely doubted. Within well-defined domains, the epistemological conclusion seems to be obvious that knowledge can be described as isolated objective entities existing independently from individuals and their experiences. Only then the idea of reaching excellence by accumulation of objectively relevant knowledge units can be expressed. This is not trivially transferable from well-defined domains to ill-defined domains like medical diagnosis, writing lyrics, etc.

The study of ill-defined domains thus is one of the most urgent desiderata in research on expertise; some evidence exists that results obtained from the study of well-defined domains cannot be directly transferred (Voss, 1990). Ford and Adams-Webber (1992) argue that a constructivistic epistemology might be more appropriate in such cases, in which (for example) the truth of knowledge is doubted. Of course, knowledge is of immense importance in ill-defined domains as well, but the nature of relevant knowledge might be different: declarative knowledge is less important, practical knowledge is more important. A helpful differentiated analysis of types of knowledge was provided by De Jong and Ferguson-Hessler (1996). The problems to be solved are more complex; the problem-solver has to show more flexibility in the use of solutions strategies (Krems, 1996). A conclusion from situated-cognition approaches is that in complex domains the situativity of knowledge and problems has to be taken into account, and that successful learning heavily depends on experience dealing with the uncertainty of domain-specific information and with the irregularity of cases to be met. It has repeatedly been doubted that systematic presentation of information

and systematic accumulation of knowledge is adequate for teaching complex skills. The constructive learner activity during learning and the kind of approach to problems and creatively solving them then is of increasing importance. This, however, suggests that individual differences in dispositions that underlie information processing might play an important role. Additionally, problem solving in relevant situations within complex domains suggests that the social context of learning processes is important; individual differences in the ability to deal with the social context are also related with the outcomes of learning. Martin and Double (1998) argued that processes of peer observation and collaborative reflection are important factors in the development of complex skills; in section 6, this argument will be addressed in more detail.

Whereas the descriptive results of contrastive studies cannot be neglected, the basic lack of research on expertise obviously concerns longitudinal studies of the acquisition of high-level performance in complex domains. First studies (e.g. Gruber, Renkl & Schneider, 1994) indicate that intensive practice within a domain may not be sufficient for the acquisition of expertise. Other conditions also play a role, that are not necessarily of a cognitive nature; reasons have to be identified why some individuals are motivated to work and practice for many years, whereas others are not.

The amount of exposure to relevant information during practice then is not the only relevant factor during learning. Many individuals were exposed to much practice and did not reach expert level, because they lacked the ability to integrate facts to derive complex insights. The interaction between dispositions and practice seems to be important even if a substantial correlation between them can not be observed in experts.

#### 4. Do Giftedness and Expertise Meet? The Lack of Substantial Correlations is No Counter-Evidence!

The relation between dispositions and practice can most clearly be analyzed by studying the role of giftedness for expert behavior. As Schneider (this volume) shows, in complex domains intelligence is not a very good predictor of expert achievement. Rather, low correlations between intelligence and level of expertise are usually found; this may lead to the assumption that dispositional factors do not influence expertise and its acquisition. There are three reasons why this assumption may not be accurate. Since the potential relation between dispositional factors and practice factors has a major impact on instructional efforts, these arguments have to be considered carefully.

(1) *“Limited variance” argument.* The lack of a substantial correlation between intelligence and level of expertise may be an artifact because the

variance of intelligence is limited to what can be observed in studies on expertise. Schneider (this volume) argued that within many domains, intelligence has to be above a certain threshold value for the successful acquisition of expertise; as a consequence, expert samples of contrastive studies usually have limited variance in intelligence. Thus, the argument that intelligence does not play a substantial role, cannot be generalized. Ackerman and Rolhus (1999) found that for middle-aged adults, intelligence significantly predicts knowledge if a lower level of expertise is assumed or if knowledge across a variety of domains is analysed. The notion of the development and maintenance of ‘intelligence-as-knowledge’ as correlates of task performance of adults implies that the scope of what is analysed as ‘intelligence’ dramatically influences the correlation between dispositional factors and practice. (In section 5, the concept of practical intelligence instead of ‘g’ is discussed as a solution for this problem.) In developmental psychology, arguments have been collected that the adequate use of the terms ‘intelligence’ or ‘excellence’ is different for different age groups (Kliegl & Mayr, 1997).

- (2) *“Drop-outs make it difficult!” argument.* The interpretation of low correlations between intelligence and level of expertise may be speculative because almost no data are available about drop-out rates and specific characteristics of the drop-outs during the acquisition of expertise. Only very few persons reach excellence—the factors responsible for this phenomenon of drop-outs have not yet been analysed sufficiently, and there is a lack of adequate longitudinal studies.
- (3) *“Different roles in different phases” argument.* In early phases of the acquisition of expertise, dispositional factors may play a larger role than in later phases, in which domain-specific knowledge becomes increasingly important. Thus, contrastive studies contain another artifact, because the sample of experts already reached late phases in development, whereas the novice sample did not even start with gaining excellence. The role of intelligence during the acquisition of expertise might be more significant in other phases than those usually considered (this argument was extended in Ackerman’s comprehensive theory of the acquisition of high-level performance which is addressed in section 5).

Doubts therefore may be expressed; even convincing evidence that intensive deliberate practice is necessary for reaching high-level performance does not exclude the impact of dispositional factors. Deliberate practice over a very long period of time requires the existence of some enduring individual characteristics that support strong motivation and commitment. “Hard work

and innate ability are very likely confounded. Those children who have the most ability may also be those who are most interested in a particular activity, who begin to work at that activity at an early age, and who work the hardest at it. One is likely to want to work hard at something when one is able to advance quickly with relatively little effort, but not when every step is a painful struggle. Thus, Ericsson's research (. . .) demonstrates the importance of hard work but in no way allows us to rule out the role of innate ability" (Winner, 1996, p. 273). It is hardly possible to isolate ability from practice.

So, on the other hand, even an assumed strong role of innate talent does not rule out the importance of practice and hard work—even the most gifted develop their performance through intense work. However, the gifted may differ from ordinary people in respect of their learning speed, their intrinsic motivation to acquire domain-specific skills, and so on; research on expertise has not yet sufficiently dealt with such analyses. As will be shown, attempts to model the acquisition of complex expertise resulted in a number of assumptions which (at least implicitly) include components of the integration of approaches about giftedness and expertise.

### 5. Interaction of Dispositions and Practice in the Acquisition of Excellence

Among the arguments expressed in the previous section, the third one, the "different roles in different phases" argument, has been elaborated in the most explicit way. For different kinds of human skills, theories have been developed that describe distinctive phases during learning, in which dispositions and practice interact in different ways.

In his ACT\* theory (and some derivatives), Anderson (1982) described three phases of skill acquisition: declarative phase, compilation phase, and tuning phase. The basic idea is that learners first require much declarative knowledge, which can be later proceduralized and recognized as patterns with associated action sequences. They can then automatize and tune skills through repeated practice. Anderson assumes innate cognitive structures for the acquisition of knowledge in the declarative phase, which he did not elaborate as much as the practice-based mechanisms of compilation (composition and proceduralization) and tuning.

With growing skills, more and more parts of the knowledge base become proceduralized, that is, practice helps to change the nature of information processes from controlled and effortful to automatized and compiled processes. Automatized processing is quick, needs few cognitive resources, and cannot easily be controlled. Its development is based upon extensive practice within consistent problem-solving conditions, that is, preferably within well-defined domains. Information processing remains in the declarative phase, if

task consistency is not present; in this case, effortful controlled processing remains necessary.

In his theory of *ability determinants of skilled performance*, Ackerman (1986, 1987, 1992) discussed the change from controlled processing to automatized processing in terms of dispositions vs. practice (cf. Mack, 1996). He proposed an hierarchical three-phase model similar to ACT\*, in which a cognitive phase, an associative phase, and an autonomous phase are distinguished. The relationship between intellectual abilities and practice is moderated by task characteristics (consistency, complexity).

The cognitive phase makes high demands on the subject. S/he has to understand task instructions, comprehend relevant goals, express strategies, memorize knowledge, etc. General, dispositional ability regarding giftedness plays an important role in this phase, which is only decreased if consistent task characteristics allow the emergence of proceduralized knowledge. In the case of inconsistent tasks, the correlation between general dispositional measures and performance is much higher than estimated within research on expertise.

In the associative phase strategies are being proceduralized; performance is increasingly bound to perception, and the compilation of knowledge leads to an increased speed of information processing.

Skills are being automatized during the autonomous phase; conscious attention for domain-specific actions is no longer necessary; in ill-defined, inconsistent domains, however, the autonomous phase is only rarely reached.

Obviously, the size of correlations between dispositional abilities and performance depends on the nature of the task or the domain. Given inconsistent demands, performance is well predicted by general abilities. If demands within a domain are consistent, more and influential processes of compilation are happening, the importance of practice increasing, the correlation between general abilities and performance is decreased. The gifted's intellectual advantages are thus more important in domains with less consistent demands. Consistency of tasks is thus related to skill specificity in learning (Ackerman, 1990): the more skilled a subject is, the more specific components of information processing are relevant, so that the correlation between dispositions and performance decreases. Characteristic of many complex vocational domains (Ackerman, 1992, worked on air-traffic control), however, is inconsistency of demands; in such domains, general abilities do not lose their importance for high-level performance.

Thus, there is some evidence that dispositional factors like giftedness or intelligence influence the nature of human information processing, e.g., the way in which individuals notice, accumulate, process, and apply the stimuli presented in their environment. The use of learning strategies, the degree of activity during

learning as well as the degree of self-regulation in learning, the skill of knowledge management or the degree of cooperative learning activities, are examples of the information processing than might be influenced by dispositional factors (cf. Weinert & Schrader, 1997). As a consequence, dispositions possess some relevance for the acquisition of excellence. It has been argued (e.g. Renzulli, 1986) that learning environments with high demands optimally foster the development of the gifted because complex learning is supported. The basic ideas of situated cognition (see section 6) include some similar thoughts.

Of course, it is not only intellectual abilities that influence information processing. Pekrun and Schiefele (1996) stressed the role of emotions for performance, e.g., through the allocation of cognitive resources, the selection of information processing strategies, the representation and recall of knowledge, or the amount of intrinsic motivation.

A number of instructional means have been developed that attempt to directly foster processes in which the gifted transfer their superior intellectual (and other) abilities in order to make progress in the quality of their information processing. General didactical advice was administered that aimed at promoting subjects' general abilities; examples are strategy training, metacognitive training, fostering of cooperative learning and social exchange, imparting values and norms, etc. (George, 1993). Teo and Quah (1999) stressed that the analysis of non-achieving behaviour of the gifted gives hints for instructional efforts. Such problems can be attributed to a lack of knowledge, volition and action of the gifted. Consequently, gifted education has to care about knowledge of the self, knowledge about volition, consultation, time management, stress management, and so on. Teachers' perceptions of the problems of the gifted play a crucial role in such instruction (Chyrwisky & Kennard, 1997).

Gifted instruction traditionally focused on the principles of developmental differentiation (Montgomery, 1996) and enrichment of the curriculum for the gifted. A couple of programs have been developed that systematically investigate possibilities of identifying and fostering high ability subjects (Heller & Hany, 1996; Mönks, 1999), e.g., 'The Study of Mathematically Precocious Youth' (Benbow, 1986), 'Purdue Three-Stage Enrichment Model' (Feldhusen & Kolloff, 1986), 'Enrichment Triad/Revolving Door Model' (Renzulli & Reis, 1986); see also the chapters on acceleration of instruction (Southern, Jones & Stanley, this volume) and on instructional enrichment (Renzulli & Reis, this volume).

Montgomery (1998) stressed the complex relationship between high ability and performance and concluded that the mechanisms of just testing and identifying the gifted do not suffice, but cognitive processes during learning have to be taken into account. Analysis of gifted thinking and problem-

solving yields a more valid basis for instructional support of the gifted (Waldmann & Weinert, 1990; Waldmann, 1996). Future development of research on high ability should thus lead to research about the nature of cognitive processes that make the gifted excel, that is, investigations about individual differences in cognitive structures and processes. Obviously, this again argues in favour of reciprocal influences of research on giftedness and research on expertise.

The implications of this proposal are clear: on the one hand, individual cognitive processes have to be analysed, and reasons for individual differences have to be investigated. For this purpose the assumptions of situated learning with its stress on active constructive processes are important. On the other hand, experts' activities are bound to specific domains and thus are part of a large social system. Social and application contexts therefore influence information processing as well. This implies that more complex conceptions of information processing than just 'g' have to be used in theories of the development of excellence (Sternberg, 1985, 1996, 1997). Sternberg and Wagner's (1989, 1993) notion of practical intelligence and practical knowledge seems to be useful for this purpose, and its instructional implications are eminent (Sternberg, 1998).

Based on his triarchic theory of human intelligence, Sternberg developed a model of intelligence in which the perspective of information processing is reflected, and which proved satisfactory in prediction of professional success. *Practical intelligence* describes how people successfully interact with their environment; it includes components of human ability of adaptation in the environment, shaping of one's own environment, and the selection of adequate environmental contexts. Learning then comprises three basic processes of selection, namely selective encoding, selective combination, and selective comparison.

The operationalization of practical intelligence differs substantially from the operationalization of 'g'. Whereas 'g' is measured via (IQ) tests that include tasks which are well-defined, lacking complex embedding, and which are presented completely, practical intelligence measures assess the skills of high-performing people (Sternberg & Caruso, 1985). Their ability is focused to apply their knowledge as a consequence of their professional experience (Gruber, 1999). The problems concerned are usually ill-defined, always embedded in relevant situational and/or cultural contexts, and they rarely appear in completely worked formats.

In some respects, the difference between 'g' and practical knowledge reflects the relation between theory and practice. As Kessels and Korthagen (1996) noticed, this relation was quite imbalanced in 20th-century research: abstract knowledge in most theories is much more appreciated than practical abilities or "tacit knowledge of good performance." After all, at

the end of the century the situated cognition movement provided ample evidence that it is a very plausible assumption that knowledge is context-bound in principle (see section 6). Accordingly, Sternberg and Wagner (1993) chose the provocative title 'The *g*-ocentric view of intelligence and job performance is wrong' to express the opinion that research on the description of excellence as well as instructional efforts to foster high-level performance should focus on the contextualization of knowledge and skills (cf. Mandl, Gruber & Renkl, 1993; Nake, 1998). Thus, they implicitly argue that research on dispositions cannot be separated from research on expertise through practice and from research on the social and cultural contextualization of human activity.

Recent models on the acquisition of expertise argued similarly, even if they did not explicitly include the giftedness argument nor the contextualization argument. However, the same topics are involved when ideas about the development of complex skills are expressed.

Boshuizen and Schmidt (1992) investigated the development of expertise in medicine. They proposed a three-phase model in which the relations between (abstract) biomedical knowledge and practical experience are changing, and are leading into an integration of theoretical and experiential knowledge in some kind of 'encapsulated' knowledge. Through professional activity, the medical doctors' knowledge undergoes qualitative changes. Declarative biomedical knowledge is proceduralized as result of experience with real cases. The resulting knowledge structures ('illness scripts') are generalized across cases, but nevertheless based on episodic experience and thus closely related to application contexts. The use of illness scripts leads to quick diagnosing without the need to effortfully activate declarative knowledge (compare with Anderson's ACT\* theory). In the first phase of development, declarative biomedical knowledge about diseases has to be gathered and learned; during this phase, individual differences in general abilities lead to differences in learning. Then, the declarative knowledge is developed into 'illness scripts' as a result of real diagnoses with patients. It is important to note, however, that the declarative knowledge remains available if necessary. But it is no longer necessary in most cases, because the knowledge encapsulated in clinical experience with cases is sufficient.

The subjectively perceived relevance of experienced episodes and the conscious reflection of these episodes plays an important role for learning. In her model of dynamic memory, Kolodner (1983) explained how episodes are represented in memory, and how people apply episodic experiential knowledge. Representing knowledge through 'episodic definitions' that include the subjective perception and assessment of episodes as well as knowledge about applicability and application errors, are key features of this model. Learning through

experience with cases alters general knowledge structures. Instructional consequences are evident: the acquisition of excellence can instructionally be fostered by fostering reflective application of knowledge through the presentation of complex learning environments in which real application situations occur and which teach the relevance of the to-be-learned. Case-based learning is a preferable mode of learning (Kolodner, 1997) in which many components are included that contribute to high-level performance. Thus, this kind of learning is suited to make best use of the advantageous dispositions of high ability learners, but it also provides ample learning opportunities for the less gifted. Learning by this means—taking individual differences in dispositions as well into account as the amount of practice and the social and cultural contextualization—is exactly what the theories of situated cognition and situated learning focus on.

## 6. Situated Cognition: Environments for Complex Learning

It has been argued that understanding the development of excellence cannot be constrained either to dispositional factors or to practice factors. A focus on dispositions (or even biological prepared structures) does not mean neglecting social processes in which learning is embedded. "Prepared structures do not substitute for learning but rather make learning possible by constraining and guiding attention." (Resnick, 1996, p. 342) The notions that mental activity involves social coordination, and that knowledge is acquired in and attuned to specific social and cultural situations, on the other hand, do not necessarily have to disappear. Even if the social nature of cognitive activity is stressed, individual differences in information processing substantially influence the learning outcome. Resnick (1996) proposed a combination of both views in the perspective of situated rationalism, which can "provide an account of how individuals learn both the universal concepts for which they appear to be biologically prepared and the much greater variety of culturally specific knowledge and ways of acting that characterize mature people. The issue addressed here is how to understand the relations between the prepared structures and the cultural domains; it is assumed that there are cultural elaborations of conceptions initially founded on the biologically prepared structures." (p. 344) Learning can then be described as tuning of prepared structures.

The resulting learning environments can be described as 'constructivistic'. They are based on two assumptions: (1) individual mental constructive (rather than receptive) activity; (2) social embeddedness of learning and, thus, perspective on the acquisition of excellence as increasing participation in expert communities of practice. Instructional psychology has to

consider both by giving the opportunity for constructive activity of learners and by preparing complex, authentic learning environments.

### *Constructive Activity of Learners*

A fundamental assumption of all situated cognition theories is that the reality is constructed by a learner based upon his/her own perceptions, and that learners do so by actively interpreting perceptual experiences in terms of prior knowledge, current mental structures and existing beliefs. Instructional psychology has to investigate the nature of and possibilities for implementation of learning environments that encourage such generative processes.

Learning, from a constructivist perspective, does not occur by passively receiving information but by actively interpreting it. Effective learning thus depends not only on the quality of instruction and of the material presented, but also on the learner's intentions, meta-cognitive skills (e.g. self-monitoring), elaboration activities, and intrinsic motivation. Despite the subjective character of learning, the learning environment needs to be highly adaptive in order to foster the possibilities resulting from the idea of learning as active, self-regulating, and reflective process.

As an instructional strategy, situated cognition has been seen as a means for relating subject matter to the needs and concerns of learners (Stein, 1998). Learning as creating meaning from the real everyday activities leads to practical intelligence. By embedding subject matter in the ongoing experiences of the learners and by relating the learning environment to the real world, knowledge is acquired in an applicable way, so that it does not remain inert and can be transferred outside the learning environment.

From the situated-learning perspective, four basic assumptions about activities during learning can be derived (Wilson, 1993): (1) learning is grounded in the actions of everyday situations; (2) knowledge is acquired situationally; (3) learning is the result of a social process encompassing ways of thinking, perceiving, problem solving, and interacting in addition to declarative and procedural knowledge; (4) learning is not separated from the world of action but exists in robust, complex, social environments made up of actors, actions, and situations. Conclusions about instructional practices can be drawn from these assumptions: theories from a situated perspective on learning propose an increased use of cooperative and participative teaching methods in order to create possibilities to negotiate knowledge through the interactions of the learner with other learners, with teachers and/or experts, and with the environment, its tools and materials.

Obviously the 'situation' plays a central role in approaches of 'situated' learning. The notion of learning as active, constructive process instead of carriage of invariable mental entities lays stress upon

the situation in which learning occurs. It is important to note that 'situation' does not only characterize material aspects, but also includes the social environment; participation in social processes plays a central role in situated learning approaches.

### *Social Contextualization of Learning*

Participation denotes the process by which learners are working together and with experts in a social organization in order to solve problems related to everyday life circumstances (Lave, 1988; Brown, Collins & Duguid, 1989). Learning becomes a social process dependent upon interactions with others placed within a social context that should—for learning to be successful—resemble as closely as possible the practice environment.

Lave and Wenger (1991) proposed a theoretical framework in which learning is conceived as situated activity which has its central defining characteristic in a process called *legitimate peripheral participation* by which learners or newcomers become *enculturated* into a *community of practice*. Both concepts, legitimate peripheral participation and community of practice, though not precisely defined by Lave's work, refer to the notion of using out-of-school learning processes as models for school learning.

The essential parts of the arrangements in a community of practice that influence learning are the relations between newcomers and old-timers, the relations among newcomers, the typical activities in the community, and the artifacts of the domain. The process by which a newcomer becomes a 'full participant' or an 'expert' is fundamentally social; newcomers as apprentices learn from the old-timers and also from the other newcomers. Even learning with physical or symbolic tools (e.g. books) is fundamentally social, because the tools as artifacts carry a substantial proportion of content knowledge that has historically grown in the respective communities of practice. Finally, learning is viewed as enculturation, not only as acquisition of knowledge. Thus, learning concerns many social aspects such as ways of speaking, belief systems, social customs, etc.

Acquiring excellence is thus not confined to the acquisition of declarative knowledge or skills but a social process of enculturation. It means to become a full participant in a community of practice that can cope with the problems typical for the respective domain in a flexible manner.

Rogoff's (1990) theoretical approach shares some similarity with that of Lave, but puts more emphasis on cognitive development in childhood. Rogoff takes up the Vygotskian notion of the *zone of proximal development* and uses the term *guided participation* to describe the process by which children learn in the course of interaction with expert partners (e.g. parents or teachers). Rogoff (1990) underlines the importance of expert modelling, active observation, guidance by more able

partners, and joint participation for the development of expertise.

Both approaches ascribe a novel role to learners who are regarded as apprentices. The learner is, right from the beginning, an active participant in authentic practices; learning and acquiring expertise are essentially viewed as processes of enculturation (Gruber, Law, Mandl & Renkl, 1995).

The conceptions of learning described above have serious consequences for the design of learning environments. The call for maximal similarity between a learning situation and application situation, which is based on the argument that knowledge in principle is context-bound, dramatically changes the nature of learning environments as well as the nature of teaching and learning processes. The consequences are as follows: (1) By using complex initial problems learners get interested, they get a notion of the relevance of the to-be-learned. Active, constructive learning processes are fostered by presentation of motivating problems in which learners perceive relevance for daily life. (2) Authenticity and situativity of learning environment enable learners to learning in near-to-application situations, and to make experiences in complex episodes of learning. (3) Using multiple perspectives on the same subject matter helps to avoid oversimplifications and enhances transferability of the to-be-learned. The learners' skill is enhanced to flexibly transfer knowledge onto a variety of problem situations. Experiencing common characteristics of episodes helps to induce general knowledge structures. (4) The methods of articulation and reflection help learners to transform concrete experience into abstract knowledge including the learner's subjective perspective and experiences.

These principles of situated learning have been realized in a couple of instructional models for complex learning; most convincingly, this has been done in the models of cognitive apprenticeship and of cognitive flexibility.

#### *Complex Learning Through Cognitive Apprenticeship*

As already described, the authors from the situated-cognition camp favor apprenticeship arrangements for learning; the apprenticeship metaphor is taken from craft domains, such as tailors or midwives. Collins, Brown and Newman (1989) have proposed an instructional approach for more cognitive domains. In the Cognitive Apprenticeship model, it is intended to introduce the learner into an expert culture by authentic activities and social interaction, just as in craft apprenticeship.

The core of the Cognitive Apprenticeship model is a special instructional sequence and the employment of authentic learning tasks; cognitive processes are externalized by experts within authentic application situations. Learning then leads the student to acquire knowledge that is applicable to a certain class of

situations; further learning takes place in sequenced learning environments of increasing complexity and diversity. At all these learning stages of the apprenticeship approach, the expert is assigned an important role as a *model* and as a *coach* providing *scaffolding*. However, the learner has to increasingly take over an active role, as the expert is gradually *fading out*. In this course, *articulation* and *reflection* are promoted by the expert, i.e. the normally internal mental problem solving processes are externalized. Thus, one's own strategies can be compared with strategies of experts and are then open to feedback. In addition, one's own cognitive strategies should be compared with those of other learners. As a result of this instructional sequence, the learner increasingly works on his own (*exploration*) and may take over the role initially assumed by the expert. This sequence resembles the development from legitimate peripheral participation to full participation described by Lave and Wenger (1991).

Ideally, the following process takes place: the learner starts out from the very beginning with authentic tasks, as far as he or she can accomplish with his or her present knowledge state, which should be corrected and enlarged in the further learning process. The teacher or expert supports the learner by modelling, coaching, and scaffolding. The expert's scaffolding helps the student to successfully cope with problems that are somewhat beyond the scope of the learner if he or she works alone. The social-communicative exchange between expert and learner as well as among different learners is ascribed a central role. By this way, the cognitive concepts and processes are articulated and thereby explicated. Thus, they can be an object of reflection which fosters the induction of more general and abstract concepts or schemata. In addition, the communicative exchange provides the opportunity for the learner to get to know the concepts, strategies, and beliefs of the expert and also of other learners that are in some respect more advanced. From this point of view, learning is a process of enculturation into an expert community; with growing skills the learner can work more and more independently; the support by the expert is gradually withdrawn (*fading*). The setting, however, keeps its cooperative character; the fading of the support formerly provided by the expert ends up with the fostering of self-guided exploration. This means that the learner attacks novel problems and works primarily on his or her own.

A critical point of all instructional models that focus on the applicability of the to-be-learned is how to make the acquired knowledge not remain bound to the very context of acquisition. In the Cognitive Apprenticeship approach, the model should not only show how to solve problems, but also explicate the rationale behind his strategies. Thus, the concrete model behavior is connected with more general principles of the respective domain. Furthermore, students should articulate

and reflect upon their problem solving strategies and compare them with others; this means should also 'free' the acquired knowledge from the very context of learning.

#### *Complex Learning by Acquiring Cognitive Flexibility*

To make knowledge applicable outside the learning situation requires the acquisition of knowledge that can be applied in many different situations. One instructional means to reach this goal is to confront the learner with a variety of situations in which the respective knowledge occurs.

Spiro and his colleagues (e.g. Spiro, Feltovich, Jacobson & Coulson, 1991) propose to employ *multiple perspectives* to make knowledge more transferable. A learner should deal with a concept at different times, in different contexts, with different purposes, and in different roles (e.g. as tutee and as tutor); thus, oversimplification and too narrow ties to a specific context are avoided.

Cognitive flexibility theory stresses the importance of providing multiple perspectives in which the knowledge to be acquired is embedded (Spiro et al., 1991; Spiro, Vispoel, Schmitz, Samarapungavan & Boerger, 1987). Cognitive flexibility theory mainly deals with advanced knowledge acquisition in ill-structured domains (e.g. diagnosis of heart diseases, literary interpretation). These domains can be described by two basic characteristics, complexity of concepts and cases, and irregularity of cases with large variability of relevant features across different cases. Instruction following the theory of cognitive flexibility aims to induce multiple and, as a consequence, flexible representations of the knowledge which can be applied for problem solving in a great many contexts. An instructional means to induce flexible multiple representations is to elucidate the same concept at different times, in different contexts, with different problem-solving goals, and from different perspectives. Only this allows the learner to create a rich collection of aspects of the same concept, which helps him or her to apply the knowledge in many different situations. Furthermore, this kind of instruction renders it possible to identify multiple relations to other concepts as well as common misconceptions and oversimplifications. Transferability of knowledge increases through multiple perspectives on the problem rather than through abstract context-free learning.

#### **Concluding Remarks**

To sum up: "Instructional psychology and the gifted" has gone beyond its own scope. Its aim of fostering the growth of excellence and high-level performance needs research on specific instructional efforts for high-ability people, but adequate fostering needs knowledge about the way in which these people process information, in which they acquire expertise, in which they make use of the affordances and constraints of the

environment, and in which they are getting members of communities of practice. Research, thus, cannot only deal with identification and fostering of intellectual abilities, but has to investigate the interaction between dispositional abilities and practice as well as the cognitive structures of expert knowledge and the social processes which help to integrate individuals in real-life application situations. In this chapter, we attempted to report evidence in favour of the argumentation, that the traditional research lines dealing with high ability on the one side, and with expertise on the other, have to be combined. Extending central concepts (like intelligence) is a necessary pre-condition for this. Instructional approaches using the concept of situated learning (in Resnick's, 1996, words: approaches that take the position of 'situated rationalism') seem to offer good starting points for such a kind of research.

# The Education and Development of Verbally Talented Students

Paula Olszewski-Kubilius<sup>1</sup> and Samuel P. Whalen<sup>2</sup>

## Introduction

Among the domains of human excellence there is none more fundamental than the capacity for language. Indeed, language and communication are so intrinsic to human experience that their absence may preclude fully human development. Past and recent studies indicate that 'wild' children deprived of early interactive speech suffer linguistic, emotional, and social deficits that permanently limit their cognitive potential (Itard, 1801/1982; Frith, 1989). And while researchers differ over the degree to which language is 'hard-wired', much about language is clearly special, both as a cognitive capacity and a medium of socialization and cultural evolution.

Yet if language distinguishes humans as a species, it also divides us; language is among the most powerful factors defining membership within ethnic and national populations. While translation is among the highest arts, nuances in accent, inflection, grammar and idiom remain elusive to non-native speakers, and act as surface markers of sub-group membership. Even within monolingual populations, subgroups defined by age, class, occupation and geographical region actively cultivate specific vocabularies and speech patterns that reinforce group identity and in-group cohesion. To the extent that such linguistic subgroups map also to distinctions between social and economic class, facility with language further implies access to economic and social opportunity.

Given the intimate links between linguistic competence, identity, and opportunity, it is not surprising that efforts to identify individual differences in verbal talent generate resistance and controversy. Disputants across a range of communities correctly perceive that the stakes involved in controlling how verbal ability is defined and measured are high (Winch, 1990). For the

community devoted to the development of verbal talent, the dual challenge has been to establish the validity of individual differences in verbal ability, while convincing educators and policy makers of their stake in the future of verbal excellence. It is a challenge complicated both by the accelerated pace of recent research into language, and by the acrid climate of controversy surrounding the contemporary 'language wars'.

This chapter first surveys five major areas of controversy surrounding language development and literacy. These debates exercise considerable influence over how linguistic excellence is understood, as well as who is understood to possess it, and how the community of practitioners most concerned with verbal talent defines itself. We then review major conceptions of verbal and linguistic ability, and go on to summarize the range of proposals to identify and educate exceptional verbal competence. Finally we suggest some core lessons learned in recent research into the education of verbal excellence, and propose some priorities for research into verbal excellence in the next decade.

## Critical Debates About Language and Literacy

We want to emphasize here debates that really impact on how the community of researchers and practitioners into verbal talent development are able to work:

First, there are issues related to the nature of verbal ability and individual differences, including:

- Is language acquisition innate?
- Is language critical to rationality?
- Is language a separate intelligence?
- Is language ability heritable?
- Is verbal ability independent of specific language or linguistic experience?

Second, issues of what should be taught?

- Bilingual education and who will be included among the verbally able?
- The cultural corpus: what books are appropriate to age groups?

<sup>1</sup> Center for Talent Development, Northwestern University, Evanston, IL, USA. E-mail: pkubilius@casbah.acns.nwu.edu

<sup>2</sup> Chapin Hall Center for Children at the University of Chicago, Chicago, IL, USA.

E-mail: whalen-sam@chmail.spc.uchicago.edu

What is the future of the written word? Does cyberspace heighten or reduce the importance of the traditional literacies?

Third, issues of how literacies ought to be taught:

Questions about ability grouping and early reading  
Technique: whole language vs. phonics

Survey any community at the dawn of the 21st century and you are likely to uncover at least one contentious issue related to language and literacy. Ubiquitous to these conflicts is an historical tension between literacy and elitism. Throughout most of history societies have cultivated elites, both religious and administrative, to exploit the powerful tools of literacy and restrict the dissemination of ideas more broadly through the society. That is, policies regarding literacy have been closely tied to political and religious philosophies and considerations, affecting both access to and applications of literacy. In the West, Medieval European theocracies tended to restrict access. Reformation theocracies challenged these restrictions, but regulated what could be expressed about religious and political matters. It is only more recently that notions such as universal literacy have been embraced. Yet modern history offers many variations on who has access to literacy, and how literacy is employed—either to reinforce old ideas, or to cultivate the development of new ideas.

In many respects what distinguishes modern democracies is the unprecedented scope they grant both in terms of access and useage of literacy, and the consistency of debate about issues of literacy. From the Modern Language Association to the local school board to the Amazonian tribe fighting to preserve its mother tongue, communities are asked to situate their specific concerns within a broader context of unprecedented, dynamic linguistic change. Discourse within the community concerned with verbal talent is influenced by a range of contemporary debates and ideas, from questions about the origins and nature of language, to questions about whether certain forms of expression and pedagogy ought to occupy a privileged position within Western culture. In this section we briefly survey five critical debates that form the broader context for thinking about the nature and nurture of verbal talent.

#### *How much of language is nature or nurture?*

In the arena of language acquisition strong differences of opinion remain about both the timing and weight of biological and social factors. These debates shape the general climate of opinion about the relative mutability of verbal ability, and the amenability of talent to environmental influence. The strongest assertion of linguistic innateness holds that linguistic ability emerges too early and too powerfully in human childhood to be explained by social influences. In

particular, purely inductive models of learning can not account for how young children surmise the syntactical and grammatical conventions in their mother tongues, with little guidance or exposure to exemplars (Wexler & Culicover, 1980; Pinker, 1989). Denying the 'learnability' of language, Chomsky has hypothesized the existence of a universal grammar whereby children instinctively orient to the fundamental patterns of spoken language (Chomsky, 1986). Other linguistic researchers, while not arguing as exclusively for innate capacity, emphasize the early operation of adaptive constraints in shaping the attention of children to patterns and regularities in human speech (Bloom, 1990; Kelly, 1992; Gardner, 1993).

Drawing particularly on the theories of the Soviet psychologist Lev Vygotsky (Vygotsky, 1962), social interactionist researchers argue that it is a mistake to ignore the essentially social nature of early linguistic exchange. Both the vocal tone and facial expressions of the primary caregiver selectively orient infants to the particulars of their primary language, from the simple phonetic level to the elaboration of word meanings and expected styles and conventions of conversation (Nelson, 1989, 1991). Cross-cultural evidence, for example, indicates that significant parameters of speech acquisition (e.g. the ratio of verbs to nouns employed) correlate closely to the emphases of maternal speech—what Nelson (1989) calls 'motherese' (Choi & Gropnik, 1995). Further, the role of psychosocial processes becomes increasingly prominent as language development moves from primary acquisition to the elaboration of more sophisticated abilities and sensibilities (Feldman, 1980; Hoff-Ginsberg, 1990; Huttenlocher, Haight, Bryk, Seltzer & Lyons, 1991). Jerome Bruner has argued for the operation of a 'Language Acquisition Support System' working in tandem with maturational processes to catalyze language development toward advanced, culturally specific modes of expression (Bruner, 1983).

#### *How heritable is linguistic ability?*

Just as brain research has fueled the biological debates surrounding language acquisition, so the explosion in genetic research has spurred controversy about the heritability of verbal ability. First, serious disagreement remains over the importance and interpretation of ethnic and racial differences in intelligence, best illustrated by the furore caused by the publication of Herrnstein & Murray's *The Bell Curve* in 1994. Proponents of these differences focus less on explaining their origins than on validating their authenticity, primarily on grounds that IQ measures are methodologically sound and largely free of cultural bias. While noting that members of all groups can be found at all points of the bell curve, they insist that group differences in innate intelligence contribute to class differences and social problems, and should be

acknowledged in shaping social policies (Herrnstein & Murray, 1994; Gottfredson, 1997).

The most general criticism of this stance points out that within-group differences are much more profound than between-group differences in predicting phenotypic outcomes, and that group differences are confounded with historical and socioeconomic factors (Cole & Cole, 1996; Sternberg, 1996). Other critics focus on the risks of cultural and educational bias posed by heavily verbal test formats (Miller-Jones, 1989). Claude Steele has argued that the conditions of standardized testing negatively impact the confidence and motivation of minority students, leading to cognitive interference and underperformance in evaluative situations (Steele, 1991).

A second sphere of controversy involves the significance of early environmental risks for long-term outcomes in adulthood. There is general agreement that environmental stressors such as poverty, family conflict and malnutrition all suppress the intellectual performance of children in the short run. Researchers differ sharply, however, over their long-term impacts. Critics of environmental effects on intelligence point to evidence that while the correlation of early risk to intellectual performance decreases with age, the concordance of intelligence to genetic affinity (e.g. identical twins vs. fraternal twins) actually increases (Fischbein, 1981). They interpret this to indicate that genetic factors tend to override environmental disadvantage over time. Proponents of environmental effects argue that cumulative advantages building within lives and across generations account for the relative intransigence of class and economic differences. Such conditions are likely to suppress or impair the expression of otherwise high genetic potential (Bronfenbrenner & Ceci, 1994).

#### *Are some languages better than others?*

Debates about language primacy or plurality are now encountered in almost all industrialized countries that have opened their borders and economies (Crawford, 1992). These debates, both interlinguistic and intralinguistic, are likely to become more prominent in the 21st century as traditionally monolingual nations are challenged to consider multicultural and multiethnic national identities. At both linguistic levels three issues are engaged. First, is one language 'better' than another in ways that warrant privileging its speech? Second, do the costs of elevating one language over others outweigh the benefits? Third, should the power of the state be brought to bear in enforcing (or undermining) language hegemony?

In the United States, for example, a vocal 'English Only' movement has emerged from regional roots to significantly influence language and education policy discussions. Organizations such as U.S. English and English First urge government action to enforce the use of standard American English in public places, and

particularly in schools. Rationales include the economic advantages posed by the globalization of English, the centrality of English to American political and cultural institutions, and the need to stem the tide of ethnic fragmentation through one common language (Arias & Casanova, 1993). Opponents of these arguments cite examples of successful multi-lingual societies and warn against the social and educational costs of monolingualism. These include the exclusion of large numbers of citizens from democratic participation, the isolation of America from the world community, and intellectual deprivation of children with no exposure to a second language (Resnick, 1991; Secada & Lightfoot, 1993).

The recent uproar over the decision of the Oakland (California) school board to acknowledge 'Ebonics' or Black English as the 'primary language' of local African American children highlights many of the characteristics of intralinguistic conflict (Ogbu, 1999). Proponents of Ebonics vary in their claims about the degree of distance between Black English and standard American forms. But they agree that urban African American children encounter significant difficulty in making the transition from their home dialect to the standard English required for success in school (Perry & Delpit, 1998; Baugh, 2000). In their view the Oakland decision aimed only to institutionalize existing curricula that approached African American children as a bilingual population at risk for school failure (Smitherman & Wayne State University, Center for Black Studies, 1981; Smitherman, 2000).

Opponents of the Oakland decision reflected the full range of opinion and anxiety about racial distinctions as public policy: many white-identified critics saw the Ebonics agenda as divisively political rather than educational. African American critics feared further stigmatization of Black students and warned that the debate would distract attention from systemic and cultural sources of Black underachievement (United States. Congress. Senate. Committee on Appropriations. Subcommittee on Departments of Labor Health and Human Services Education and Related Agencies., 1997). The emotionality of the debate suggests how language can become a lightning rod for more fundamental questions of social justice, racial identity, and educational opportunity, including the chance to develop excellence in the idiom of one's early and most formative experience.

#### *Are some books better than others?*

Another contentious debate between conservative and progressive voices in pluralistic societies involves the content and legitimacy of the literary canon. In a number of countries this debate pits the supposed 'Great Books' of the mainstream tradition against a range of challengers, old and new, embodying voices

and opinions at odds with the cultural elite. On the one hand advocates for conservation of the canon argue for both the cultural and educational importance of a restricted range of classic texts and ideas. These texts represent a time-honored source of 'cultural literacy' for the young, a focus of cultural cohesion for civic society, and a standard of excellence toward which the most talented members of each generation may aim. While the strongest arguments for a restricted canon align closely with political conservatism (Hirsch, 1987), it should be noted that attention to the canon as an educational resource is common to a number of reform proposals (Adler, 1982; Sizer, 1984; Gardner, 1999).

In the United States the agenda of cultural literacy collides most directly with the emphases and commitments of multicultural education (Sleeter, 1995). Two proposals are common to most multicultural approaches. First, the challenges of tolerance facing a pluralistic society demand an education that acquaints future citizens with a diversity of cultures and ideas. Stringent adherence to one cultural canon thus incurs prohibitive intellectual as well as civic costs. Second, for literacy to thrive, children must be able to identify with the themes and characters in the literature they encounter. Failure to provide culturally accessible materials to immigrant and minority children in particular can cause disengagement from full verbal development, leading to inequitable educational outcomes. Many multiculturalists view early experiences of cultural incompatibility as the key to later shortfalls in literacy among historically disenfranchised minority children (Tharp, 1989; Ogbu, 1991).

Finally in many parts of the world state censorship continues to significantly restrict the range of ideas available to stimulate literary development (Lunsford, Moglen, Slevin & Modern Language Association of America, 1990). The overall impact of censorship on intellectual freedom has receded dramatically since the end of the Cold War, while in the West battles over overt censorship tend to focus on isolated texts (Edwards, 1998). Nonetheless to the extent that verbal excellence thrives in an atmosphere of intellectual plurality, censorship remains among the fundamental international obstacles to literary development.

#### *Are some forms of instruction better than others?*

Several controversies involve how best to instruct and cultivate literacy and verbal excellence. At the inter-linguistic level arguments about the aims and techniques of bilingual education continue to impact directly the quality of instruction available to students of minority language households. In the United States debate about the techniques of Spanish bilingual education reflects fundamental differences in understandings of American pluralism. The strongest multicultural advocates combine support for sustained

Spanish language instruction with a broader agenda of language diversification. Opponents argue that most ESL students adapt to English quickly, and require only limited bilingual structure to transition effectively to full English immersion. Recently the latter argument has significantly altered the commitment to bilingual instruction in states such as California and Texas (Arias & Casanova, 1993; Brizuela & Garcia-Sellers, 1999).

The most protracted debate regarding the instruction of literacy involves the contrast between phonetic and whole language approaches to early reading and writing (Nelson & Clafée, 1998). These approaches rely on contrasting models of verbal development, models that often do not adequately encompass the needs of precocious verbal learners. In Chall's view of phonetic development, for example, novice readers lack the decoding skills necessary to bridge from symbol to sound; the process of reading alters qualitatively from the early labor of decoding to the mature pleasures of interpretive reading. Reading proficiency is accelerated to the extent that decoding strategies are taught and encouraged; failure to teach these skills particularly impacts the educational prospects of poor and minority children (Chall, Jacobs & Baldwin, 1990).

The 'whole language' view gives higher prominence to experiences of meaning, enjoyment and activity early in literacy development, with special emphasis on the needs of language minority learners (Goodman & Goodman, 1990). This reflects a view of language development that sees children as active language makers, and formal literacy as a further extension of early language play. Emphasis on the conventions of literacy (e.g. 'correct' spelling) is replaced with activities that integrate reading, writing and listening as media of meaningful learning. More recent whole language approaches embed phonetic instruction within highly interactive contexts of literacy development (Adams, 1990; Brown, Campione, Reeve, Ferrara & Palincsar, 1992). However, neither phonetic nor whole language curricula narrowly applied are well matched to the often autonomous and highly self-motivated learning styles of verbally precocious children (Winner, 1996).

To conclude, this review can only suggest the broad matrix of critical questions about language and literacy in which more specific debates about exceptional verbal talent are located. On the near horizon, for example, are profound questions about technology and the future of communication. Increasingly children are engaged in a diverse range of written and verbal activities in cyberspace that challenge the conventions of formal schooling and family socialization (Kerr, 1996). How the internet will shape the literacy of the next century and the media of verbal excellence remains to be seen, but it will undoubtedly contribute to shifts in our contemporary map of verbal potential. In the next sections we review how verbal ability

currently is conceptualized, as well as the present state of the art in identifying and nurturing verbal talent.

### Psychometric Definitions

Verbal ability or verbal talent can be and is often defined by performance on standardized tests, such as IQ and achievement tests. Most IQ tests or broad scale assessments of intellectual ability consist of subscales, including ones that measure constructs called 'verbal ability', 'verbal concepts', or 'verbal comprehension'. Some tests give a separate score for a composite of the verbal subtests; the WISC III for example, yields a verbal IQ score, a performance IQ score, and a full scale score. The Cognitive Abilities Test gives verbal, quantitative, and non-verbal composite scores. In educational practice, the verbal subtest scores are often used as a measure of verbal ability and high scores are considered indicative of exceptional verbal ability.

The types of items included within a verbal subtest or verbal subscore vary greatly. They are usually a mixture of items that directly assess information taught in school and items that require a child to draw on information acquired in school and/or informally in other settings. The arithmetic and vocabulary subtests of the verbal portion of the WISC are illustrative of the former type and the similarities and comprehension subtests of the WISC are representative of the latter type (Flanagan, Andrews & Genshaft, 1997). Although most intelligence tests do have a verbal subtest(s), the extent to which academic achievement-like items (the first type described above) are included varies greatly; for example, 50% of the items of the Test Composite of the Stanford Binet IV and the WISC Full Scale IQ are of this type compared to only 14% of the items of the Woodcock-Johnson Revised Tests of Cognitive Ability (Flanagan, Andrews & Genshaft, 1997).

Because of the mix of types of items on most verbal tests, there is some discussion within the literature as to whether they are measures of fluid or crystallized intelligence.

However, because the knowledge that is necessary to respond correctly to verbal items on intelligence tests is dependent on accumulated knowledge and experience, that derives from living in mainstream American culture (or other highly industrialized societies), in addition to formal education, the verbal scales of intelligence tests may be interpreted more appropriately as measures of crystallized intelligence (Flanagan, Andrews & Genshaft, 1997, pp. 461).

The mix of items within a verbal intelligence scale affects the interpretation of its predictive validity and its usefulness for deciding upon educational interventions. Scores from different tests may predict children's future performances equally well but tests that are comprised of tasks of information processing may be more meaningful in terms of deciding upon educational interventions than scores on tests that are

composed of achievement-like tasks. In practice, scores on verbally laden achievement-like tasks are more readily available to educators and therefore, more typically used for educational placement or selection into special programs.

Studies involving children with a wide range of abilities indicate that the relationship between verbal IQ and general IQ is moderate and varies with the age of the subject. For younger children (early elementary school aged children), scores on different subtests are more highly inter-correlated than they are for older children (pre-adolescence). A young child's relative standing in one ability, e.g. verbal, is highly predictive of his/her standing in others, e.g. quantitative. Not so for older children whose patterns become much more variable. For an older child, a profile showing the relative standing on each subtest is more informative and valuable than a composite IQ score. These trends with age may or may not be true of gifted children and there is some evidence to suggest that gifted children exhibit variance in subtest performance earlier than non-gifted children (Winner, 1996). There is also evidence that children who exhibit strength in the quantitative area have more varied cognitive profiles than children who exhibit strength in verbal areas (see later sections for a fuller discussion of this issue).

Verbal intelligence is maintained into old age and shows a sharp decline just before death (Hunt, 1978). Scores on verbal intelligence tests are not predictive of precocity in specific verbal skills such as early reading but precocity in oral language is an indicator of later high verbal intelligence in children (Jackson & Kearney, 1993; Jackson & Klein, 1997).

Achievement tests also include verbal and quantitative subtests. Typically, verbal subtests include tests of reading comprehension, vocabulary, decoding or word attack skills, spelling, and language mechanics.

Prior research indicated that girls scored higher on aspects of verbal ability, as assessed by standardized achievement tests, compared to boys, particularly in the elementary grades (Macoby & Jacklin, 1974). A more recent meta-analysis conducted by Hyde and Linn (1988) on the magnitude of gender differences in verbal ability concluded that most observed gender difference on verbal tests are so small as to be considered negligible. Specifically, gender differences on subtests such as vocabulary, reading, analogies, essay writing are small to negligible. The single area in which females substantially outperformed males was the quality of speech production,  $d = +0.33$ ; However, the meaning of this finding is not clear. Males performance on the Scholastic Aptitude Test is slightly better than females, but the effect size is small ( $d = -.11$ ).

Stanley, Benbow, Brody, Dauber and Lupkowski (1992) conducted an analysis of 86 nationally standardized tests for gender differences and found that males almost always outperformed females. They found

small effect sizes favoring females for the Test of Standard Written English (TSWE) of the Scholastic Aptitude Test (SAT) and the American College Test–English Usage test (ACT–E), a slight advantage for males on the SAT–Verbal and PSAT–Verbal (females had historically outscored males on the SAT–V until 1972.), no differences between males and females on the verbal portions of the Graduate Record Exam (GRE) or the Law School Admissions Test (LSAT), and a small effect size (0.19) favoring females on the verbal subtest of the Graduate Management Admissions Test (GMAT).

Stanley et al. found small (0.08 to 0.09) effect sizes favoring females for College Board Achievement Tests in French and English Composition but moderate effect sizes favoring males for tests in Biology, American History, and European History, which presumably rely on strong verbal skills such as vocabulary and reading comprehension. On Advanced Placement (AP) exams, there were small effect sizes favoring females on German Language and French Literature and small to moderate effect sizes favoring males for subjects using verbal skills such as Biology, American History, and European History.
