Stanley and his associates note that while most researchers believe that gender differences on standardized tests aren't large and are getting smaller, even small differences can have a significant impact, particularly on whether females will qualify for high status programs of study. They report the largest effect favoring females for the spelling subtest of the Differential Aptitude Test (DAT). Differences also favored females on the language usage and clerical speed and accuracy subtests of the DAT for students in grade 8–12. Lohman (1994) concurs that females' advantage over males is greatest for spelling tests, intermediate for tests of grammar and style, and non-existent on general measures of verbal comprehension.

Since the early 1980s, the SAT and ACT have been used to identify mathematical and verbal talent among 7th and 8th graders who are already scoring well on standardized in-grade achievement tests. Among the middle school students who take either the ACT or SAT as part of a talent search program, mean differences favor females for the ACT English and Reading but are small and probably of negligible effect size (Center for Talent Development, 1998).

What is not clear is the meaning of high scores on verbal subtests of IQ tests or standardized achievement tests. IQ and achievement test scores are predictive of general school achievement. However, the relationship between verbal ability as assessed by standardized tests and achievement in specific performance areas is less clear and may be dependent upon the nature of the subject and the way it is taught. For example, Gustin and Corazzo (1994) found that SAT–Verbal was more predictive of performance by gifted middle school

students in a summer, fast-paced biology course than SAT–Math while SAT–Math was predictive of performance in quantitatively oriented science courses such as physics. An important question is how does verbal intelligence measured in childhood or adolescence relate to achievement or choice of career in adulthood. Benbow (1992) demonstrated that scores on the SAT–M obtained in the 7th or 8th grade was related to the pursuit of careers in science and mathematics ten years later. Similar evidence regarding the predictive validity of SAT–V or other verbal measures has not been presented.

### **Gardner and the Multiple Intelligences Approach to Verbal Talent**

Gardner postulates the existence of a linguistic intelligence among his list of eight intelligences. According to Gardner (1983), there is substantial evidence across many criteria that supports the autonomy of human competencies in the linguistic area. Gardner's criteria (1983) for the existence of a separate intelligence include the following: that the area of the brain primarily responsible for those functions can be isolated by brain damage; the existence of idiot savants, prodigies and other exceptional individuals with the intelligence; an identifiable core operation or set of operations; a distinct developmental history of the intelligence along with a definable set of end state performances; an evolutionary history for the intelligence; support from experimental psychological tests for the intelligence; susceptibility to encoding as a symbol system; and support from psychometric findings.

Gardner states that individuals who are aphasic can perform very well on cognitive tasks that are not related to language. For example, individuals who are severely aphasic may not be able to write or be authors but they will retain their abilities to be musicians or artists. This supports the existence of a specific area of the brain, the left hemisphere, as the primary locus for language functions.

There are three core functions of language, phonological discrimination and production, the pragmatic uses of language, and the semantic and syntactic uses of language (Gardner, 1983). Further, Gardner says that there are four aspects of language that are very important to human society: the rhetorical function of language or the ability to use language to convince others to take a course of action, the mnemonic function of language or the use of language to remember information, the role of language in explanation and teaching, and the metalinguistic function of language or the capacity for language to explain itself.

The ontogeny of language in humans is well documented from the first babblings of infants to the sophisticated use of language by poets, writers, and

orators. Individuals with highly developed levels of linguistic intelligence can be easily identified and found in writers, politicians or evangelists with unusual rhetorical powers, story tellers, poets, novelists. The one criteria which Gardner (1983) postulates for which there does not seem to be a lot of evidence is the existence of idiot savants or prodigies. In fact, Feldman (1986) says that child prodigies in writing are very rare because the field has few organized supports or strategies for instruction and because children normally lack the kind of experience, insight, and understanding needed to convey complex thoughts in language. Piirto (1992) disagrees and believes that writing prodigies occur more frequently than previously thought. According to Gardner (1983), while oral and written forms of language draw on the similar capacities, written language, in addition, requires the author to supply the context that is often apparent from non-linguistic cues.

We have already reviewed the evidence regarding psychometric findings in support of verbal talent above, another of Gardner's criteria. In the next section, we review the findings on experimental and verbal information processing types of tasks. However, for both areas of research, there is support for the existence of individual differences in verbal ability and skills. There is also support for a relationship between verbal psychometric measures and performance in related, verbally laden, school achievement tasks. What is less well established is the relationship between individual differences on psychometric or information processing tasks and gifted adult performances and between information processing type tasks and achievement in school subjects (see Lohman's results below as an example). These seem to be important evidence that is needed to support the existence of a linguistic intelligence.

Language is a very sophisticated symbol system. It is interesting to speculate about the relationship between facility in one symbol system such as language and others such as those involved in mathematics, computer languages, musical notation, and the alphabet. Jackson (1988) has investigated this issue with early readers and found that children who speak early do not necessarily read early and children who read early do not necessarily have high verbal intelligence as measured by standardized tests. Early code breaking as is involved in precocious reading may be related to a very specific facility with decoding symbol systems that later takes the form of musical or mathematical talent. Further research in this area is also needed.

Gardner's theory of multiple intelligences, including his assertions regarding the existence of linguistic intelligence, are still considered largely speculative. His theory offers a useful rubric to think about cognitive abilities as they relate to performance in various school subjects and skill areas (e.g. mathe-

matics, language, arts) and to achievement in domains of adult activity (e.g. scientific research, writing).

### Other Definitions of Verbal Talent

Benbow and Minor (1990) studied the cognitive profiles of verbally vs. mathematically talented students. They identified students who were mathematically gifted (SAT-M above 700 before age 13), students who were verbally gifted (SAT-V above 630 before age 13), and students who were both mathematically and verbally gifted (met both score criteria). They gave students a variety of subtests drawn from well known standardized tests to assess speed of processing, memory, spatial visualization, non-verbal reasoning, vocabulary, knowledge of English expression, and mechanical comprehension. The mean score of the students on each test was approximately equal to students who were 4 to 5 years older. After a factor analysis of all the tests used, analyses revealed that the mathematically talented students outperformed the verbally talented students on the spatial/speed and non-verbal reasoning factors which included the spatial visualization test, the clerical speed and accuracy test, the mechanical comprehension test, and the Ravens Progressive Matrices test. The verbally talented students did better than the other groups on the verbal factor which included the assessments of vocabulary and knowledge of written English. The authors suggest that their results indicate that enhanced speed and memory are more strongly associated with mathematical than verbal talent. Benbow's and Minor's findings established that verbal and mathematical precocity are distinct forms of intellectual giftedness with unique intellectual profiles.

One interesting finding was that the presence of exceptionally high verbal ability increased the likelihood of the presence of exceptional mathematical ability. Only one of the verbally exceptional students had an SAT-M score of less than 500, while the reverse was not true. Benbow and Minor (1990) suggest that verbally talented students may be more even in their cognitive profiles than mathematically talented students. This finding is reiterated by Winner (1996); who asserts that it is far rarer to find verbally precocious children who do poorly in maths than the opposite pattern because these students can use verbal strategies to solve mathematical problems. According to Winner, children who are mathematically precocious are less balanced in their skills and more likely to achieve lower overall IQ scores than children who are verbally precocious.

Dark and Benbow (1991) studied the relationship between intellectual precocity in mathematical vs. verbal areas and a variety of working memory measures using different types of stimuli. They were interested in basic memory processes such as the accuracy with which information is maintained in working memory, the accuracy with which information

in working memory can be manipulated by associating it with other information, and the speed with which information is activated from long term memory into working memory. Subject groups were defined by differential performance on SAT-V and SAT-M as above. They found that mathematical talent was associated with better memory for digit and spatial location stimuli while verbal ability was associated with better memory of word, but not letter stimuli. The authors suggested a 'differential compactness' theory to account for their results. Verbally talented individuals have more compact word representations and mathematically talented individuals have more compact representations of digits and locations. Their results also showed that quantitative ability was associated with slower loss of information from working memory. A correlate of verbal ability was the speed of activating a word's representation from long term memory into working memory; verbally talented individuals have quicker access to the word like stimuli that are stored in long term memory. The authors concluded that enhanced working memory functions are associated with mathematical talent while exceptional speed of encoding is more strongly associated with verbal talent.

Hunt, Lunnborg & Lewis (1975) undertook a study to determine if there was a relationship between psychometrically defined verbal intelligence and information processing tasks. They identified college students who were considered verbally talented by virtue of their performance on the Washington Pre-College Test (WPCT). The verbal composite on the WPCT was a weighted sum of performance on the spelling, reading comprehension, vocabulary, and English usage subtests. Hunt et al. found that one of the abilities of the high verbals was being able to make a rapid conversion from a physical representation to a conceptual meaning—that is to recognize a particular visual pattern as a word or letter. Another ability of the verbally talented students was facility with retaining information about the order of stimulus presentation within short term memory. Lohman (1994) asserts that this latter aspect of verbal ability underlies phonological fluency, a component of exceptional and precocious reading. Hunt and his associates concluded that it is possible to distinguish low and high verbal university students who were identified via standardized psychometric tests by their performance on information processing types of tasks.

Lohman (1994), whose interests include the high spatial individual as defined by performance on visual spatial tasks, asserts that there are gender differences favoring females in sequential processing of letter or phonemes or linear order codes. These differences account for females slight advantages, compared to males, on spelling tests and tests of grammar and linguistic style. According to Lohman, phonological awareness which includes knowledge of phonetic

coding or spelling is among the best predictors of reading performance and in other forms, of foreign language aptitude.

### Components of Verbal Ability

Another way to think about verbal ability is to break it down into its component parts. There are two perspectives from which to do this—that of adult performances and products and that of the skills or subjects that children study and acquire.

We can identify many areas of adult productive performance that rely on verbal skills and performances; these include all forms of creative writing such as poetry, short stories, and novels, and writing of a more informative kind such as non-fiction books, journal articles, or newspaper, or magazine writing. Verbal talent underlies exceptional oratorical performances such as is evident in acting, speech-making, or debating. Verbal ability would also presumably be involved in facility in foreign languages such as is found in interpreters or individuals who easily acquire a foreign language or read, write, and speak many languages with ease. There are many other adult professions that could require a high level of verbal ability such as law but do not readily yield critically acclaimed, observable verbal products. Exceptional adult performances and/or products presume a high level of ability but not necessarily childhood precocity in the domain; also, it is not clear that higher levels of verbal ability lead to more exceptional performances or products, beyond a certain, albeit high, minimum level.

From the perspective of skill acquisition, components of verbal ability could include early speech, an advanced receptive or productive vocabulary, early reading, early writing, or early facility with foreign language acquisition.

What is the evidence regarding precocity in any aspect of verbal ability and later talent? There is very little research on these issues with the exception of early reading.

Precocity in the production and comprehension of oral language in infancy or early childhood is a predictor of later verbal intelligence at least as measured by standardized tests (Jackson & Klein, 1997). The age of production of first words by a child is predictive of level of verbal intelligence. However, it is also reported in case studies that many highly gifted adults began speech production later than most children but, once begun, it proceeded very rapidly (Jackson and Klein).

Case studies highlight the variety of patterns of exceptional verbal skills found in children. According to Winner (1996), Michael Kearney, a very gifted boy who finished college by the age of 10, uttered his first words at 4 months of age and began reading off of a television screen at age 8 months. Michael was also very precocious in mathematics.

Similarly, David had an excellent receptive vocabulary and also began to speak at the age of 8 months, about four months earlier than most children (Winner, 1996). By age 5, David showed interest in language as a system—he wanted to learn other languages and made up his own. He read phonetically at age 3 and was able to read words he did not understand. By the time he entered kindergarten, he was reading at a 6th grade level. He was also advanced in writing, producing non-fiction pieces and stories at age 5. Michael and David were two examples of children who showed precocity in both the verbal and mathematical areas, which Winner admits is more the exception than the rule.

Raphaella (see Winner, 1996) spoke her first words at age 9 months and spoke in long, complex sentences by the age of 2 years; she was reading at age 3 and read chapter books by age 5. At the same age her writing was advanced; she could read cursive writing. She spelt correctly from the start and not phonetically; she was somewhat advanced in mathematics but not remarkably so. Her drawings and physical development were also age appropriate.

These examples of verbally precocious children raise several issues; one is the relationship between precocity in one area of the verbal domain and precocity in another, e.g., early reading and early writing. A second is the relationship between precocity in two very different domains, mathematics and verbal. According to Winner (1996), despite the examples of Michael Kearney and David, unevenness is typically the pattern across disparate domains. Similarly, according to the research conducted by Jackson and her associates, young children who produce or understand language at unusual levels do not necessarily read early (Jackson & Klein, 1997).

The evidence regarding precocity in writing is also equivocal. Feldman (1986) asserts that writing is not an area in which prodigious achievement typically occurs; he also notes that writing prodigies rarely become writers in adulthood. However, Feldman does report on a child, Randy, who was exceptional as a child at least in the amount he wrote and his use of language. Randy's father was a writer and thus could provide an unusual amount of support for his writing activities; his father was his first teacher. Randy showed an early interest in words and their tonal qualities; he began to read without instruction at age two and a half. He wrote constantly about everything he read and studied. According to Feldman, Randy's strength as a writer was in his evocative use of language to set tone and create a style but not in his ability to tell a really good story. Only occasionally did Randy express powerful emotions or feelings in his writing; his spelling was also exceptional.

Randy had many other interests including music and acting; he eventually pursued these more vigorously than his writing although he continued with his writing

to some extent. Feldman (1986) notes that typically, when talent emerges very early, parents serve as the first teachers. Eventually, another adult takes over the instructional process; but in writing, there are few mentors available to children to serve as teachers or role models. Also, writing is a lonely craft and for Randy, the draw of performing in front of an audience, made it and other endeavors more attractive.

Piirto (1992) claims that the reported incidence of writing prodigies may be inaccurately low due to inadequate documentation. She lists 16 qualities of advanced writing of children including the use of paradox, parallel structure, rhythm, visual imagery, unusual figures of speech, reverse structure, unusual adjectives or adverbs, unusual melodic combinations, a feeling of movement, uncanny wisdom or humor, sophisticated syntax, prose lyricism, an 'ear' for the rhythm and sounds of language, a philosophical or moral bent in writings and a playfulness with words. Characteristics of outstanding prose writing include giving a refreshing twist to old ideas, keeping ideas within a story organized, and choosing descriptive words that show perception and precision. Piirto asserts that the characteristics of children with creative writing talent include early and voracious reading and attention to words and expressions of words. Piirto agrees that precocity in writing is not necessary for adult achievement and says that incipient writers are characterized by high emotionality and strong imaginations.

According to Bailey (1996), writing development has its roots in drawing, an interesting hypothesis that has not been studied to any great extent. Bailey asserts that most 3 year olds would not be able to tell a true story in response to a picture; what they would produce would be more like a description of the picture. A *verbally gifted* 3 year old can tell a logical and creative story. By age 5, dialogue would be used creatively and the story could be highly imaginative and include expressively vivid and complex language.

By far, the most well researched area of early precocity is that of reading; most of this work has been done by Nancy Jackson and her associates. Jackson (1988) notes that many eminent individuals are purported to have been early and voracious readers; she raises the interesting question of the meaning and significance of early reading. After all, advancement in reading does not last; eventually other children who start at the normal time catch up. Does early reading have any predictive value or long lasting effects? Jackson (1988) argues that even if we cannot answer that question, it is clear that early reading has *immediate* profound effects because it alters the way teachers and parents respond to and interact with a child.

As stated earlier, there is no relationship between early oral language fluency and precocious reading (Jackson & Klein, 1997). Early reading is not necessarily a start to an excellent career in school and

precocious readers may or may not have high verbal IQ's (Jackson & Klein); they may or may not be exceptional or early writers. As a group, early readers tend to be somewhat above average in IQ and most tend to remain at least above average in reading (Jackson, 1992, 1988).

Precocious readers differ in their specific subskill patterns. Some precocious readers rely on phonics and can decode virtually any word. Others rely heavily on context to decipher new words (Jackson, Donaldson & Cleland, 1988). The most critical factor is a child's ability to use relevant knowledge or reading strategies effectively, appropriately, and flexibly (Jackson, Donaldson & Cleland, 1988). Thus, there are individual differences among precocious readers in what and why they read as well as how they do it. The most striking feature of precocious readers is their ability to read text very rapidly (Jackson & Klein, 1997) although not more precisely than a comparative group (Jackson, 1988). Precocious reading is associated with the ability to name letters rapidly, which indicates a more general ability to quickly retrieve information from long term memory.

Jackson proposes that precocious reading has a heterotypic pattern of continuity, which means that it is part of a trait that gets expressed in different ways with age. Precocious reading has diverse roots and diverse sequelae (Jackson & Klein, 1997). Early reading may be indicative of later interest and remarkable performance or achievement in another symbol system such as music, computer languages, or mathematics. Efficient processing of auditory-sequential information may underpin exceptional representation and retrieval of phonological information and abstraction of oral-graphemic rules leading to early reading and, somewhat later, early exceptionality in music (Jackson & Klein). Alternatively, efficient processing of visual-spatial information may also lead to early reading and somewhat later, exceptional achievement in mathematics (Jackson & Klein).

There may be more of a contribution of specific teaching to early reading than has been thought. Burns, Collins & Paulsell (1991) studied four year olds who had a Stanford-Binet IQ of 120 or higher; some were readers and some were not. At age 4 there were no significant differences between the readers and non-readers on listening comprehension, understanding of concepts about print, ability to recite the alphabet, or ability to verbalize the names of written letters. Accelerated readers did perform better on tasks which asked them to read specific words in print, use invented spelling, or verbally produce vowel and consonant sounds when shown corresponding letters. It was found that the majority of mothers of readers (66%) had used reading kits or programs at home with their children and the remaining readers had received formal reading instruction in their preschools. At ages 8 and 9, the readers did significantly better than the non-readers in

using phonetic analysis to identify nonsense words or to spell dictated words; there were no differences on word identification or comprehension, key aspects of reading. However, the authors suggest that more differences might have existed at ages 8 and 9 had the early readers continued to be exposed to an accelerated or advanced language arts curriculum during the early elementary grades.

### Research Findings on the Development of Verbally Gifted Adults

Retrospective studies of talented adults reveal a complex picture of the talent development process including the following factors—personality characteristics of the individual, environmental circumstances and supports, access to mentors, and childhood experiences. The group of individuals who have been studied and written about most extensively are writers.

VanTassel-Baska (1996a, 1996b) has studied the development of female writers including Virginia Wolfe and Charlotte Bronte. She discovered eight themes that were characteristic of these women: adversity typically involving the deaths of close family members and/or poverty; autodidacticism or self-learning sometimes resulting from a lack of access to formal education and consisting of informal instruction from family members or literary family friends; practice of the craft which often included daily journal or diary writing; need for emotional support (which came from others and also from their own writing) because they lacked confidence in their writing; vulnerability to criticism and high strung personalities; a defined philosophy of being which involved believing that one was subject to the whims of impersonal 'fate' but could also rise above difficult circumstances to create something of beauty; the influence of place which showed in the use of familiar locations and childhood environments as settings for stories; loneliness which was evident in the lack of friends and the erratic nature of friendships due in part to lifestyle and location; and the search for a mother figure and understanding of a mother's role which was often a theme within their writing.

VanTassel-Baska (1996a, 1996b) also identified four stages of development of the talented female writers. The first stage was a family that valued the literary and intellectual life and spoke freely about the world of ideas; this period was also characterized by opportunities for the child to spend time alone indicating a more isolated and atypical childhood. The second stage consisted of an informal early development of the craft of writing; during this stage, the child engaged in imaginative play, played with words in writing, and created skits and plays. An important element of this early experimentation was an audience, usually consisting of family members who provided constructive

feedback. The third stage was an active experimentation with the various forms and genres of writing. The final stage was the development of a mature form in successive works.

Simonton's (1986) research suggests that writers tend to be from cities, have small, non-religious families with non-supportive fathers and generally unhappy home environments. Many experienced severe childhood trauma such as the loss of a parent, alcoholic parents, or serious illness, their own or their parents.

As children, writers were often very responsive to the emotional climate and stresses of their family household. They were often compelled to retreat away from these situations into reading or daydreaming, which often facilitated the development of their talent. Writers, as children, had intense imaginational and intellectual reactions to the written word (Piiro, 1992). They tended not to be joiners, preferring to be alone, and did not care for physical activities. Many writers reported hating school and school curricula (Piiro).

Writers' personalities tend to include the characteristics of independence and unconventionality (Piiro, 1992). On the Meyers Briggs Type Indicator, writers are found to be introverted, intuitive, feeling, and perceptive, a profile that is similar to visual artists (Piiro). Many writers are also artistic and/or have great interest in the visual arts (VanTassel-Baska 1996b); distinguished writers are frequently schizoid, depressive, hysterical, or psychopathic. Many were self abusive and self destructive. Writers may write because of deep seated pathologies and their writing is often an outlet for childhood trauma (Piiro).

Writers are risk takers; they must submit manuscripts over and over again risking rejection and criticism; they are characterized as resilient, stubborn, persistent, and good at self promotion (Piiro, 1992).

According to Piiro (1992), writers value productivity; the number of pieces a writer produces is related to his or her success. More successful writers produce more written pieces overall. Simonton's (as cited in Piiro, 1992) research shows that poets reach their peak of productivity at age 39 on the average and fiction and non-fiction writers at age 43.

An important environmental component of a writer's development is a group of connected friends—particularly other writers who can provide support and constructive criticism. Often this means living in areas of cities where writers are known to live (Piiro, 1992). "The 'loft culture' of artists . . . also exists in the writing world. Writers keep in touch with one another and often seek to establish themselves through public readings, which unfortunately, are frequently attended only by other writers." (p. 148, Piiro, 1992). Friends can help get a writer's work published; for many writers, the first works were published by small presses or by one friend for another. While writers need one another they often feel threatened by other writers.

Another critical component of a writer's environment is the literary agent (Piiro).

### **Educational Programs for the Development of Verbal Talent**

Educational programs for children with verbal talent vary widely. These include grouping arrangements that allow children who possess advanced skills to proceed at a faster pace or do accelerated work (e.g. reading groups), early foreign language study, or comprehensive, integrated language arts programs for high ability learners. Most programs in early elementary school focus on the area of reading since this is such a crucial and fundamental skill area. Few programs for elementary school aged children single students out for special instruction on the basis of advanced writing ability, exceptional creative writing ability, exceptional spelling ability, or facility with foreign languages. In most cases, school personnel rely on in-grade achievement tests to identify children who are performing above grade level in reading or language arts and to place them in special, advanced programs.

According to VanTassel-Baska (1996b), characteristics of verbally gifted learners upon which a program should be built include: reads well and fluently, is interested in words and word relationships, uses an advanced vocabulary, processes key ideas about what is read, enjoys talking about literature, writes descriptively and communicates a story, enjoys verbal puzzles and games, reads often and outside of class, plays with language in its oral and written forms, and exhibits understanding of the structure of language in speaking and writing. Bailey (1996) adds, fluid and descriptive oral language, advanced ability to use a linguistic symbol system, ability to express a complex thought, and playful doing of a skill coupled with a seriousness of purpose.

Programs at the junior high or middle school level may include strong literature programs with literary analysis by genre or theme as a major focus. Writing may be incorporated into the literature class or be a separate strand, particularly a focus on the development of strong non-fiction writing skills. Foreign language study typically begins in high school but many schools now begin instruction in middle school or even in the elementary grades.

High school programs for verbally talented youths include the International Baccalaureate program which helps to prepare students for facility with another language. It also emphasizes writing in the formal exams that students take in order to obtain the prestigious IB diploma. A key component of the program is a 4000 word research report.

The Advanced Placement program (AP) of The College Board has many courses that are appropriate for verbally talented students including AP English Literature and Composition, AP Language and Composition, and AP courses in several foreign languages and

the social sciences. AP courses give high school students the opportunity to study college level material; students can, by examination, earn college credits for these courses.

Other options for secondary students include dual enrollment programs which currently exist by legislation in 19 U.S. states. These programs allow students to be simultaneously enrolled in high school and college. Students can take college courses on college campuses, and usually earn both college and high school credit for them. With the increasing use and capabilities of the internet to reach remote audiences, distance education programs can allow verbally gifted youths to take advanced courses in many language arts areas. These courses may be high school or college level courses.

Other opportunities for verbally gifted youths include summer programs, study abroad options, and contests and competitions. Summer programs abound in the U.S. and many of these have courses for verbally gifted youth in writing, literature, foreign language, debate, philosophy and the social sciences. Many of these are connected to talent search programs and rely on SAT and ACT scores for entrance. Study abroad programs offer a unique opportunity for students to learn about another culture and acquire facility in a second language at a high level. Contests and competitions can give students an outlet for their writing, an opportunity to have their work evaluated by a professional writer, chances for publication, and potentially cash prizes or scholarship money.

An important question is what should be the components of a program for verbally gifted youth. These might include foreign language study, reading or literature study, writing, oral communication, or language and grammar study. Reading/literature and writing are most typically included in programs for verbally gifted youths. Thompson (1996) recommends, however, that language/grammar study is also an essential component of the education of verbally talented youth; the study of language includes grammar, vocabulary, etymology, and poetics. Language study offers gifted students content that is complex and abstract; it is inherently interdisciplinary according to Thompson. It "is an enabling curriculum that will strengthen students' abilities in all other curricula and invigorate their powers of articulation for all purposes" (p. 152). Thompson goes on to say that "because grammar is so often studied as a thing in itself, an intellectual amputation severed from its context of living ideas in literature, poetry, and other forms of language, it is easy for us to forget what a decisive analytical thinking technique grammar can be in the interpretation of literature and poetry" (p. 153, Thompson, 1996).

Thompson and Thompson (1996) suggest that foreign language study begins early in the elementary school years; they stress that foreign language study can develop verbal ability in a way that the study of

one's native language cannot. The advantages of studying a foreign language include a deeper understanding of language, accelerated vocabulary development, new understanding of grammar through comparison between the native and foreign language, training of the poetic ear, ability to read literature in another language, mental flexibility gained through knowledge of language elements that are non-existent in the native language, and a multicultural perspective. According to these authors, studying a foreign language forces one to become more language conscious in general. Further, the study of foreign language is interdisciplinary because the student does not just study the language but also the culture, history, literature, geography, and customs.

Speaking and listening activities of a higher level are frequently not a component of the school curriculum; these could include forensics, debate, or rhetoric. According to Chaney (1996), oral communication should be conceptualized as 'thinking in action' and involves listening, non-verbal communication, information gathering, synthesis and analysis of arguments, comparison of alternative choices, identification of values, and giving and responding to feedback. Students who can read and write at high levels of proficiency may not be able to communicate orally at the same level. All students, but particularly those who are verbally talented, need and can benefit from experiences that can systematically develop speaking and listening competencies.

Very little in terms of special language arts curricula for gifted learners exists; most programs rely on using materials designed for older learners to increase complexity and abstractness of the content. Consequently, there are few evaluations of the effects of specialized curricula designed for gifted learners (VanTassel-Baska, Johnson, Hughes & Boyce 1996). These authors studied the impact of a 40 hour language arts curriculum designed for gifted learners in 4th through 6th grades. The curriculum was integrated and used selected literature, writing exercises, and a self-study grammar packet and was employed with seven experimental groups. Performances of the experimental students on a reading assessment, a performance-based persuasive writing task, and a grammar test were compared to three control classes. Results showed large effect sizes favoring the experimental group on the grammar and writing assessments and small effect sizes for the reading test. The authors suggest that their data support the use of more powerful language arts curricula for high-ability learners.

### Conclusions

What can we conclude about the development of verbal talent and the education of verbally talented youths? At this point we can easily and quite reliably identify children with high scores on certain types of tests that we believe measure meaningful aspects of verbal

ability and that predict performance in verbal subjects or school tasks. Most researchers would agree that verbal ability is multi-faceted, consisting of skills, components, or subparts, even though they may not agree on what they are nor their importance relative to one another or to expert-adult performances. There are only a few studies about the more basic cognitive processes such as memory or encoding processes that underlie exceptional verbal abilities; more research is needed in this area.

We are also unclear about the emergence of certain components of verbal ability and the significance of precocious emergence in children with the exception of early reading. The connection between drawing and literacy skills in young children is worthy of investigation and the work of Jackson and her associates on the relationship between early reading and other domains offers hope for a more comprehensive, in-depth understanding of the development of symbol use.

As is the case in many areas of gifted education, curricula for verbally talented children have developed despite a lack of clear consensus on the construct of verbal ability. Well developed programs exist particularly at the secondary level. In elementary school, the heavy emphasis on reading has precluded the systematic development of other verbal skills; this is an area where change is vitally needed. Also required are more studies of the VanTassel-Baska et al (1996) variety in which special curricula for gifted learners are implemented and their effects studied.

# Nurturing Talents/Gifts in Mathematics

Wilhelm Wiczerkowski<sup>1</sup>, Arthur J. Cropley<sup>2</sup> and Tania M. Prado<sup>3</sup>

## Introduction

Reliable diagnostic strategies and error-free identification of any psychological characteristic are difficult without a satisfactory operational definition derived from an unequivocal theory. Thus, the first step in considering strategies for nurturing giftedness in mathematics is to make a clear statement of what is actually meant by the construct. This definition determines how highly gifted pupils are to be identified (selected), and what measures are to be included in special provision aimed at nurturing their gifts.

The variety of conceptions of mathematics leads not only to varying perceptions of what mathematical giftedness is, but also apparently affects the contents of instruction and the way information is imparted by instructors (Wagner & Zimmermann, 1986; Zimmermann, 1992). These aspects have not been explicitly discussed in scientific debate to date.

Aspects of mathematical giftedness are, not least, an expression of subjective experience and expectations of the individual person. Statements on mathematical giftedness and its structure exhibit commonalities and uniformity as well as specificity supposedly stemming from different philosophies of mathematics (Steen, 1979, 1981) and the rich variety of aspects within mathematics (David & Hersh, 1981).

Decisive predictors of giftedness are not restricted to special skills or the degree of development of certain abilities or special aptitudes at a particular time. Of equal importance are the interactions of potential with personal characteristics such as motivation and task commitment, as well as with environmental factors including level of support or challenge at home and at school in a particular area of knowledge. Excellence can, in this sense, be regarded as the optimal goal for the development of the gifted, not as a fixed state. According to this view, the unfolding of talent is a continual reorganization of the internal structure of knowledge and the metacognitive competencies of an

individual, according to the person's stage of development.

## Mathematical Core Variables in Research on Intelligence

The parameters of mathematical ability have occupied the interest of researchers for more than fifty years. Two central questions have recurred over and over again:

1. Is mathematical giftedness an expression of specific cognitive characteristics, or is it simply the result, at least to a considerable degree, of high general intellectual ability?
2. Is mathematical giftedness a uniform construct, or are there many different profiles of exceptional mathematical ability?

Questions such as these are not simply of academic interest; depending on the answers, quite different strategies of special provision would be implemented.

As a rule, research on intelligence from the Thirties to the Sixties concentrated on general factors of intelligence, and did not look into explicit parameters of mathematical giftedness. Specific factors of intelligence such as spatial relations, visualization and orientation, numerical facility, reasoning, induction, deduction, and flexibility (see the overview in Pawlik, 1968) were first introduced in studies involving unusual proficiency in solving mathematical problems (Siegvald, 1944; Terman & Tylor, 1954; Maccoby & Jacklin, 1974; Lloyd & Archer, 1976; Merz, 1979; Halpern, 1986). Since early research on the structure of intelligence (e.g. Thorndike, Thurstone Guilford) was basically concerned with attributing complex cognitive processes to general operations (primary factors), the relative lack of attention given to specific abilities, such as those related to mathematical giftedness, is understandable.

Areas of achievement strength in different individuals or within homogeneous groups were ascertained by means of profiles on scales of general ability. This procedure is still common in current test diagnosis, and is also regularly applied when describing components of mathematical giftedness. In this context, more general cognitive operations such as ability in abstract-

<sup>3</sup> University of Hamburg, Germany.

ing concrete problems, the ability to generalize, flexibility, reversibility of operations, fluency of thought, or strategic decision-making have been regarded as core variables for mathematical giftedness.

The main objection to the use of general ability parameters for defining mathematical giftedness lies in their lack of specificity. In order to facilitate understanding of a special gift (or special measures to nurture it), it seems reasonable to assume that the primary cognitive operators mentioned above are not interchangeable across specific academic domains such as mathematics, biology, physics or even the social sciences. In the case of mathematics, concepts of general academic giftedness should, at the very least, be augmented by identifying potentially relevant specific characteristics, which should then be analyzed to ascertain their importance for mathematical talent (Sternberg, 1981; Dummer, 1983; Heid, 1983; Gardner, 1983).

### Structure of Mathematical Abilities

The Russian psychologist Krutetskii made a significant contribution to understanding the nature and structure of specifically mathematical abilities. He showed that there are three components: reception; processing; and retaining of mathematical information (see Table 1). These are closely related and influence one another, and constitute a complete integral system or distinctive syndrome of mathematical talent: the mathematical cast of mind (Krutetskii, 1976, p. 350). According to this view, mathematically gifted schoolchildren are mainly distinguished from the less talented by internalized qualitative differences in cognitive processes. This

discipline-related analysis of talent has been accepted by other researchers (e.g. Bright, 1977; Marjoram & Nelson, 1985), but is still relatively loosely defined.

According to Krutetskii (1976, p. 351), characteristics such as speed of mental processing, computational ability, memory for symbols, numbers and formulae, ability in spatial concepts, and ability to visualize abstract mathematical relationships and dependencies are not absolutely vital for high mathematical aptitude. However, it cannot be denied that in maths lessons some students master tasks rapidly and effectively with the help of such abilities; apparently they enable the students to apply internalized cognitive processing strategies with great success. More recently, Kiesswetter (1985, 1988, 1999) has argued that the core of purposeful mathematical thinking is the systematic organizing of insights and findings into higher order structures. He identified six 'mathematical activities' which he regarded as central to this process (see Table 2). The most striking feature of these activities is their operative mode or the 'action' definition entailed in them. In this system, mathematics is understood to be an active process of devising theories, in the course of which four steps can be identified: (1) ascertaining constellations (questions) of interest; (2) focusing on the mathematical question under consideration and specifying the steps involved in its solution; (3) creatively and with the help of heuristic procedures arriving at new terms, mathematical formulations, proofs and broadly applied lines of attack; (4) placing the established interconnections within a network (Kiesswetter, 1992, p. 11).

According to this approach, mathematical giftedness manifests itself in the form of complex thinking

Table 1. Structure of mathematical abilities (Krutetskii, 1976, p. 350).

#### *Obtaining mathematical information*

- The ability for formalized perception of mathematical material, for grasping the formal structure of a problem

#### *Processing mathematical information*

- The ability for logical thought in the sphere of quantitative and spatial relationships, number and letter symbols; the ability to think in mathematical symbols
- The ability for rapid and broad generalization of mathematical objects, relations, and operations
- The ability to curtail the process of mathematical reasoning and the system of corresponding operations; the ability to think in curtailed structures
- Flexibility of mental processes in mathematical activity
- Striving for clarity, simplicity, economy, and rationality of solutions
- The ability for rapid and free reconstruction of the direction of a mental process, switching to a reverse train of thought (reversibility of the mental process in mathematical reasoning)

#### *Retaining mathematical information*

- Mathematical memory (generalized memory for mathematical relationships, type characteristics, schemata for arguments and proofs, methods of problem-solving, and principles of approach)

Table 2. System of complex mathematical activities (Kiesswetter, 1985).

- 
- (1) Organizing materials
  - (2) Recognizing patterns or rules
  - (3) Changing the representation of the problem and recognizing patterns and rules in this new area
  - (4) Comprehending and working with highly complex structures
  - (5) Reversing and inverting processes
  - (6) Finding (constructing) related problems
- 

processes. These can be identified even in young people by using a relatively open approach such as that of the *Hamburg Test for Mathematical Giftedness (HTMB—Hamburger Test für Mathematische Begabung)*, which was developed along the lines of Kiesswetter's variables. It recognizes in its evaluation not only correct answers, but also the sensible application of these six activities (Wagner, Zimmermann & Stüven, 1986). High scores in the test indicate probable success in creative work within mathematical domains and/or related areas (Wagner & Zimmermann, 1986).

Essentially, this approach regards mathematical giftedness as involving special ways of looking at and attempting to solve mathematical problems, what Zimmermann (1998) called 'active structuring'. It involves higher order thinking, which has the following characteristics: (a) it is non-algorithmic (i.e. the pathway to the required solution is not specified in advance); (b) it is complex; (c) it often yields multiple solutions; (d) it requires 'nuanced judgment' from the learner (i.e. there are choice points where the learners must decide between lines of attack on the basis of experience, intuition and the like); (e) it involves multiple criteria; (f) it involves uncertainty; (g) it requires self-regulation; (h) it requires that the learner impose meaning on apparent disorder, rather than discover a pre-existing meaning. These characteristics can be contrasted with those of thinking aimed at acquisition of fixed knowledge that is then reapplied, in the case of talented individuals with great speed and accuracy (Resnick & Resnick, 1992).

Resnick and Resnick also emphasized the 'executive processes' necessary for higher order thinking; these encompass what are referred to later in this chapter as 'metacognitive' aspects of learning. They include: (a) keeping track of one's own understanding of the issue under consideration; (b) organizing attention; (c) organizing available resources; (d) reviewing one's own progress. To these can be added (Frederiksen & Collins, 1996) (e) effectively representing and solving problems; (f) choosing more promising approaches when existing ones fail to yield a solution; (g) understanding how systems work; (h) applying this understanding. The ability of students to articulate their

own metacognitions is also of considerable importance. Articulation permits conscious self-reflection, highly specific feedback (correction) by teachers, and discussion with other learners of methods, precise differences between approaches, and similar topics.

### Mathematical Giftedness from the Perspective of Gifted Youth

Theoretically derived systems for describing talented activities do not, however, necessarily accord with the experiences of mathematically gifted students actually dealing with mathematical problems. Former participants in the Hamburg Talent Searches aged between 16 and 20 (N=234; male=174, female=60), of whom 71 took part in the *Hamburg Tutorial Program in Mathematics* for up to six years, responded to a questionnaire containing 63 items. The factor analytic approach yielded six dimensions, four of them cognitive (general traits; memory for symbols, numbers, formulae and principles; mathematical structures and patterns; visualization of problems and relations), one task oriented, and one creative (see Table 3). Thus, there is quite a strong resemblance to Renzulli's (1986) three-dimensional model of giftedness, according to which talent is a combination of high intelligence, creativity, and goal-directed motivation. This approach has been supported by other authors too (Wieczerkowski & Wagner, 1985; Mönks, 1992; Mönks & Mason, 1993).

In the view of these highly achieving young students, as Fig. 1 shows, cognitive flexibility (factor V) is the most important dimension, followed by perception of structures and patterns (factor IV), the ability to visualize abstract problems and relations (factor VI), and sensitivity to the aesthetic value and elegance inherent in a solution. In these aspects, differences between persons who participated in the tutorial program and those who did not were not significant, but they were highly significant in task commitment (factor II) and memory for symbols, numbers and principles (factor III) ( $p < 0.01$ ). Tenacity in problem-solving, ability to concentrate, ambition, goal orientation, i.e. facilitative working habits, and memory for formulae, etc. were given less importance for excelling in mathematical activities by those

Table 3. Six aspects of mathematical talent from the perspective of gifted youth.

I. General Trait	Understanding and empathy	0.679
	Emotional stability	0.612
	Originality of formulation	0.605
	Sensitivity	0.604
	Originality in connecting ideas and information	0.585
	Unusual suggestions	0.572
	Fantasy	0.566
II. Task Commitment	Tenacity in problem-solving	0.763
	Task commitment	0.727
	Goal orientation	0.719
	Ambition	0.702
	Constancy in mastering tasks	0.696
	Permanent readiness to learn	0.605
	Ability to concentrate	0.537
III. Memory for Symbols, Numbers, Principles	Memory for formulae	0.730
	Memory for numbers and symbols	0.676
	Memory for relations	0.637
	Memory for methods and principles	0.604
	Swift and precise calculations	0.603
	Memory for mathematical proofs	0.549
	Reconstructing learning process	0.480
Searching out most obvious solutions	0.431	
IV. Mathematical Structures and Patterns	Striving towards elegance in solutions	0.636
	Sensitivity for the beauty of a solution	0.574
	Perception of structure	0.534
	Abstracting concrete problems	0.515
	Interest in complex systems	0.494
	Recognizing formal structures	0.484
V. Flexibility in Mathematical Abilities	Flexibility of thought	0.734
	Inversion of thought processes	0.508
	Shifting representational level	0.437
	Flexible application of solution principles	0.384
	Generalizing a problem in terms of a problem area	0.346
	Trying various approaches to a problem	0.324
VI. Visualization of Problems and Relations	Ability to visualize problems	0.776
	Imagining spatial relations	0.774
	Ability to imagine visually	0.768
	Visualizing abstract relations	0.738

included in the program, apparently an effect of the special tutoring they had received.

Defining mathematical giftedness as successful cognitive problem solving in various areas emphasizes the importance of discovering the inherent structure of a problem and finding adequate operations for solving it.

As a rule, this may well be a nonlinear process, for which appropriate knowledge and thinking strategies or, in the sense of Bauersfeld (1988), ease of interaction among areas of experience and a high level of goal directedness and achievement motivation, may be prerequisites. Experimenting by trying out different

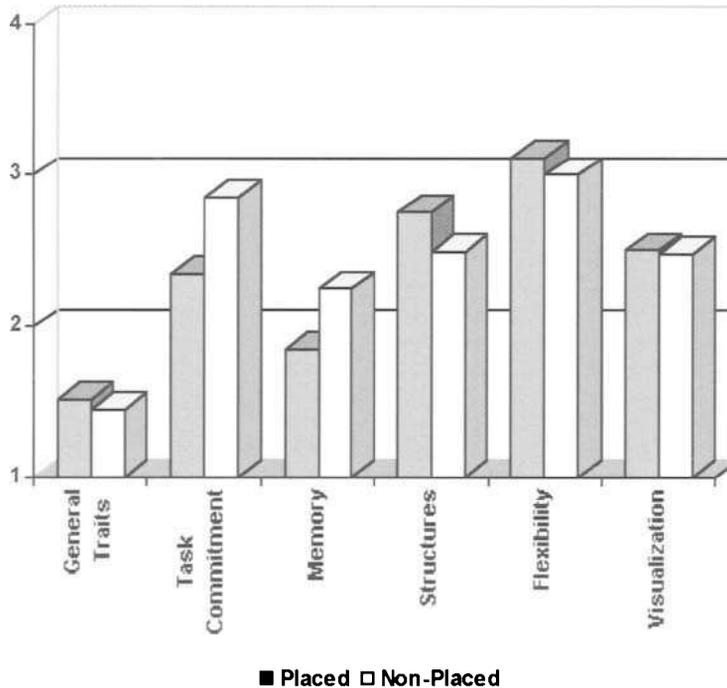

Figure 1. Aspects of mathematical talent

lines of attack on a problem then becomes a very important part of the complex system of mathematical behavior exhibited by talented young mathematicians.

### Mathematical Excellence as a Developing State of Mind

The idea that giftedness is 'in process' and that the development of special ability involves changes in the internalized structure of a discipline achieved by an individual has often emerged in scientific research (cf., Geuss, 1981). According to this point of view, giftedness unfolds hand in hand with ongoing work in a given field. Abilities are then extended within a dialectical relationship between subject and (learning) object, that is to say, between the learner and the subject material. This conception, which sees changes in cognitive structure as the result of constant interaction of existing structures with accumulated and new experience, has been put forward primarily by Piaget (1970).

Such an interactionistic-constructivistic perspective has been emphasized in most recent discussions of mathematical giftedness by, among others, Bauersfeld (1988, 1987). Two fundamental qualities of processes are mentioned: (1) being able to shift easily from one subjective reality to another, and (2) being able easily to form new subjective realities. According to Bauersfeld (1988), there are six steps within these constructivistic processes that correspond to meta-

cognitive competencies worked out by Sternberg (1981, 1985) (see Table 4).

An analysis such as this probably comes closer to the problem-solving process than do ability-oriented definitions of mathematical giftedness. It must be added, however, that mathematical activities of young people will not always follow this ideal algorithm of thinking linearly and without interruptions to the course of progress (Zimmermann, 1992).

### Quantitative vs. Qualitative Approaches to Defining Mathematical Giftedness

A crucial conceptual issue in this context is the distinction between the development of mathematical giftedness as a *quantitative* phenomenon, according to which development would be understood as accumulation of greater quantities of conventional, standard knowledge and skills (i.e. acquiring, ever larger quantities of the same), and as a *qualitative* phenomenon. In the latter case, development is seen as a series of cognitive advances involving acquisition and perfection of new kinds of strategies and systems for dealing with mathematical material, rather than as increasing the extent of existing knowledge and skills. Sheer quantity of mathematical knowledge at an early age involves one form of giftedness, to be sure, but this is different from the giftedness resulting from the development of higher order cognitive and metacognitive skills. Adopting a Piagetian position, Case (1979)

Table 4. *Metacognitive analysis of progress in mathematical activities (Bauersfeld, 1988).*

Recognizing the problem	Activating relevant subjective realities (constructions)
Planning strategies of problem-solving	Finding an appropriate initial approach
Selecting steps of action	Choosing from among a wider range of alternatives because of realities created by the learner
Mental representation of the problem	Finding a concise, condensed and generalized form of representation
Distributing attention	Frequent shifting of perspective and looking at wide overview of connected topics (This facilitates complex decision making)
Monitoring solution related process	Monitoring the informational network at each phase of the process

identified a fifth phase of cognitive development beyond the stage of formal operations. In this stage, second-order relations are recognized. Sternberg & Dowling (1982) extended this to third-order relations (analogies between analogies). Commons, Richards & Kuhn (1982) also argued for a fifth stage, the stage of 'Systematic Operations', at which operations are carried out on classes to build systems, as well as for a sixth stage of 'Metasystematic Operations' involving operations on systems.

The discussion of qualitative and quantitative approaches to mathematical giftedness can be linked to the general distinction between thinking aimed at finding the one only correct answer to a problem (referred to as 'convergent thinking' in the tradition of Guilford, 1950) and thinking aimed at producing novelty (to follow Guilford, 'divergent thinking'). It is possible to be very successful in school via the application of convergent thinking. However, there is evidence that at university (e.g. Cropley & Field, 1969) or in practical settings (e.g. Facaoaru, 1985), not only in Arts but also in Science and Technology, a combination of knowledge of the facts, logical thinking, speed and accuracy (i.e. convergent thinking) with branching out, seeing unexpected possibilities and finding novel solutions (divergent thinking) is necessary for gifted performance. Cropley (1994) argued that this combination defines 'true' giftedness.

This line of argument suggests that defining mathematical giftedness as simply mastering conventional knowledge at an early age (the quantitative approach) would lead to emphasis on convergent thinking in programs and strategies for fostering it, whereas the qualitative approach would emphasize divergent thinking. However, Cropley (e.g. 1992) warned against 'going overboard' for divergent thinking. While essential for true giftedness, divergent thinking is not sufficient; mastery of basic facts, speed, accuracy, rapid recall of material from memory and similar factors are also part of mathematical giftedness.

Fundamental cognitive processes such as retrieving, associating, synthesizing, transforming and construct-

ing analogies are important for the production of novelty, but these must be accompanied by interpreting, inferring, shifting contexts, hypothesis testing, and searching for limitations (for more detailed discussions see Finke Ward & Smith, 1992). However, the production of mathematical novelty is not simply a matter of diverging from the traditional in an unregulated, more or less random process, in the hope that effective novelty will be produced by 'brute force' (Simon, 1989). What is needed are, on the one hand, control processes that make it possible, for instance, to distinguish in advance between promising lines of attack and dead ends, and on the other evaluative strategies and skills that make it possible for the individual to reject or modify inappropriate solutions, recognize promising aspects of rejected solutions, and use these in new attacks on the problem. The metacognitive aspects of effective mathematical activities listed in Table 4 thus take on renewed importance.

#### **Non-cognitive Factors in Mathematical Giftedness**

The metacognitive components of giftedness such as frequent shifting of perspective (see Table 4) require not only knowledge and skills, but also personal characteristics such as flexibility, openness (for the new), or tolerance for ambiguity, as well as confidence in oneself in the form of positive self-image. Also of considerable importance are motivational factors like curiosity, willingness to take risks, and task commitment. In research on the question of why some schoolchildren are willing to invest a great amount of time and effort in striving for mastery of a discipline such as mathematics—i.e. why they are motivated to study it intensively—Wiczerkowski (1998) identified two subjective factors: on the one, hand children's assumptions about the difficulty of mathematics, especially in relation to their own perceived ability to master this degree of difficulty, on the other, their assessment of the value and importance of mathematics, including its interestingness, its ability to help them satisfy personal needs (for success, social stand-

ing, and a feeling of self-worth), and its usefulness in achieving life goals (academic success, a good job, and the like).

Thus, although there is little doubt that attitudes to mathematics, mathematics-related self-concept and estimates of the utility of mathematics are closely linked to objective factors such as level of skill in the discipline and past success in the area, they are also affected by children's self-image and their stereotypes about mathematics and people who engage in it. Although he was writing about creativity, Csikszentmihalyi (1996) emphasized the role of the social environment in fostering such subjective aspects of giftedness by stressing the necessity of a 'congenial' environment. This is characterized by tolerance of differences, openness for the new, positive attitudes to novelty, and willingness to reward clever failures, to give some examples.

Considerations such as these permit a broader understanding of Krutetskii's concept of a mathematical cast of mind and how to foster it. His approach was essentially cognitive and couched in terms of 'abilities', although elements such as 'flexibility' or 'striving for clarity' touch on personality or motivational aspects. However, it is now apparent that a special cast of mind would be characterized not only by abilities but also by non-cognitive components such as willingness to expend great effort on mathematical issues (motivation), placing a high value on mathematics (attitudes and values) or seeing oneself as capable of being successful in the mathematical field (self-image). A strategy for fostering mathematical ability would thus have as its goal provision of a mathematically 'congenial' environment that promoted both cognitive and non-cognitive aspects.

### Gender Differences in Mathematics Achievement

Although the evidence for gender differences in mathematics achievement is not unequivocal across the full range of ability, differences in achievement between gifted boys and girls have repeatedly been reported in both North America and Europe (for detailed discussions, see LeMaistre & Kanevsky, 1997; Wiczerkowski & Prado, 1990). Among gifted children, boys are regularly observed to do better in mathematics and to show greater interest in the discipline; these differences are seen not only in school performances such as grades or choice of mathematics as subject specialization, but also in out-of-school activities such as participation in maths-oriented summer programs or in mathematics competitions.

Typical explanations of the causes of gender-related differences in mathematics (see LeMaistre & Kanevsky, 1997) have emphasized cognitive differences, either global (such as greater speed of certain functions of the central nervous system or superior right hemisphere performance in boys), or more specific (such as superior spatial relations or pattern

formation in boys). It seems that there may well also be cognitive differences of the kind referred to here as 'qualitative'. Linn & Hyde (1989), for instance, showed that on the SAT-M girls typically (although naturally not exclusively) preferred to solve test items by reapplying standard algorithms in a meticulous but time consuming way. Boys, by contrast, often produced intuitive and fast solutions that gave them more time to attempt more items.

Some explanations emphasize particularly strongly that differences between boys and girls are acquired during the interactions of individual males and females with the conventions, beliefs, habits and values of the culture in which they grow up (see Wiczerkowski & Prado, 1990, 1992). The position adopted in this chapter (intellectual talent is a dynamic phenomenon that develops as a result of an interaction between an individual's potentials and a particular set of environmental conditions) suggests that the latter approach is more fruitful.

According to Wiczerkowski and Prado's analysis, the culture makes certain assumptions about sex roles that may be seen as stereotypes of what is typically 'male', and what is 'female'; these are maintained and transmitted in the typical family, in the form of attitudes and goals. The child develops a self-image and goals with regard to certain areas, for instance mathematics, while these areas acquire a subjective value for the child. Finally, the child develops expectations of success or, of course, of failure.

On the basis of a study of 436 12-year-old participants in a mathematics talent search (292 boys and 144 girls), Wiczerkowski (1998) identified two basic 'orientations' in the children's academic interests: on the one hand, an orientation towards musical-artistic pursuits, on the other towards scientific-technological activities. Independent of level of ability, these orientations encapsulate the kinds of activity that are seen by individual young people as capable of satisfying their needs. They define the immediate goals pursued by the individual, but do not necessarily develop into long term interests (i.e. a scientific-technological orientation in a young person promotes interest in learning mathematics, but may or may not lead to a career in mathematics).

Two findings concerning subject orientations in girls are of great interest here; even mathematically talented girls showed a significantly lower level of interest in science and technology than boys. In girls, the strength of the scientific-technological orientation increased with increasing level of achievement in relevant subjects, but this was not the case in boys. Wiczerkowski (1998) concluded that this was the result of sex-role stereotypes: boys regard themselves as talented in science and technology regardless of achievement (as of right, as it were), whereas girls need to convince themselves by obtaining high grades, since sex-role stereotypes indicate that girls are not good in

these areas. Mathematically-talented boys judged their own ability more favourably, chose independently to enter a special program for the mathematically able, and expected to be successful. Girls, by contrast, were more modest in their self-estimates, needed encouragement from their teachers and parents to take part in the program, and estimated their likelihood of success less favourably than boys.

According to analyses of this kind, problems for girls in developing mathematical talent include (see also Feldhusen, VanTassel-Baska & Seeley, 1989): more rigid stereotypes than for boys; greater fear of failure in an 'unknown', atypical subject area; less favorable self-image with regard to mathematics; lower ability to recognize their own strengths; and lack of conviction of the worthwhileness of studying mathematics. This means that measures for fostering mathematical talent in girls need, to a degree greater than for boys, to go beyond the cognitive aspects of mathematics achievement, paying more attention to aspects such as communicating high expectations to girls and avoiding overprotection, encouraging them to take on difficult tasks, even if this risks failure, encouraging them to trust in their own ability, supporting mathematical interests outside school, and encouraging friendships with children with similar interests.

### Strategies for Promoting Mathematical Talent

As has already been pointed out, the above discussions are not simply academic in nature, but are of great practical importance for the design of programs for fostering mathematical giftedness; practical consequences can be demonstrated with the help of a simple example from teaching practice. The authoritative *Third International Mathematic and Science Study* of the *International Association for the Evaluation of Educational Achievement* (IEA) evaluated videotapes of 8th grade mathematics instruction in over 200 American, German, and Japanese classrooms. German and American teachers concentrated on imparting standard skills; teachers demonstrated standard solutions to problems, then gave the students further problems of the given type, requiring them to apply the solution just demonstrated in a more cookbook manner. By contrast, Japanese teachers required students to work out their own solutions to problems and then discussed the wider application of these solutions in class. Japanese children were the third best achievers out of 41 countries in the project, whereas the Germans reached place 23 and the Americans place 28.

Educational programs for gifted students can be classified within a two-dimensional system, with one dimension involving instructional settings (in-school vs. out-of-school), the other the special approach to provision (acceleration and enrichment). This two-fold formal structure is made more complex by the additional aspect of grouping according to either ability

or interest. Although both of these criteria are, in practice, applicable to the same program in most cases, ability or interest groupings are of significant importance for placement and selection when considered separately. Programs in advanced mathematics for the mathematically highly able and interested can be divided into several types using the dimensions just outlined: whether they are offered in or out of school and according to the dominant didactic ideas underlying them (acceleration vs. enrichment). A two-dimensional matrix cannot, of course, account for the wide range of programs for the gifted; the sheer number of programs for the highly gifted at regional, national and international level thwarts any effort to ascertain their structure (see Fig. 2).

### Acceleration and Enrichment

Traditionally, a distinction has been made between acceleration (children cover conventional material in less than the usual time, for instance by grade skipping or by enrolling in special classes that work at a faster rate than usual) and enrichment (the children are exposed to material from outside the traditional curriculum, for instance in resource rooms or through the visits of resource teachers). However, more recent discussions (e.g. Stanley, 1986) have concluded that the two approaches are merely two sides of the same coin. In the most obvious variant of this arrangement, children work through the conventional material faster than foreseen in the curriculum plan, in order to free up time for additional activities such as resource room or resource teacher, visits from knowledgeable members of the public, or excursions. Another variant involves giving the children material from higher classes as enrichment; the two could also be combined.

However, the argument that acceleration and enrichment more or less inevitably go hand in hand fails to distinguish between the quantitative and qualitative approaches outlined above. It is undeniable that acceleration (learning the usual material faster) is essentially the same as enrichment if the latter consists of no more than doing more difficult or more complex examples of the usual material. However, when enrichment is understood qualitatively (i.e. exposing children to material of a different kind and not just to more difficult or more complex examples of the usual), it becomes apparent that acceleration and enrichment are not simply different organizational forms of the same thing. In this sense it is possible to imagine acceleration without enrichment, as well as enrichment without acceleration; despite this, it may turn out that, in practice, a combination of the two is most effective.

### Exclusive Grouping

Exclusive grouping requires satisfying a prerequisite for participation, and is based on three types of preselection: selection with the use of objective ability tests, placement on the basis of previous extraordinary

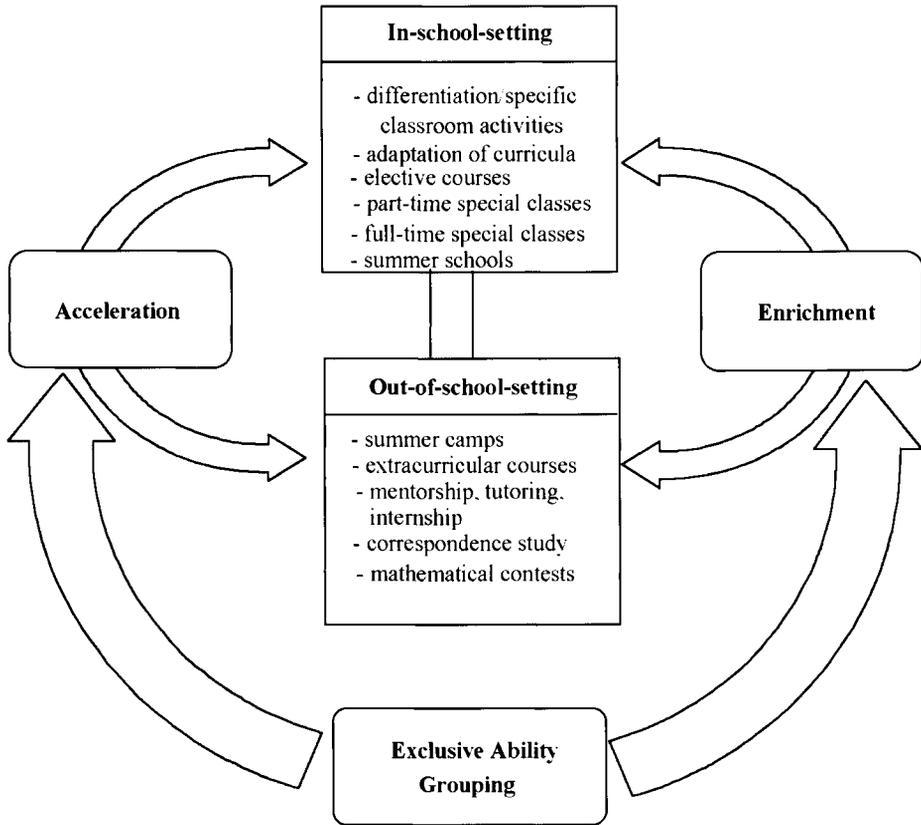

Figure 2. Strategies for special provision for the mathematically gifted

achievement in regular class instruction, or strong interest in mathematics. These three criteria are not mutually exclusive, and often come into play in combination. On the one hand, interest in mathematical problems is almost always tied in with a higher level of achievement and conception of oneself as a bright achiever. On the other hand, the readiness to demonstrate one's own skills in a talent search and to take part

in a program is, as a rule, coupled with exceptional interest in mathematics. Generally, grouping procedures follow a four-step strategy (Fig. 3):

*Individually Paced Sequences vs. Open Syllabus*

Two different tutorial models, applied by the *Center for Talented Youth (IAAY at the Johns Hopkins University)* and the *William Stern Society for Research on Gifted-*

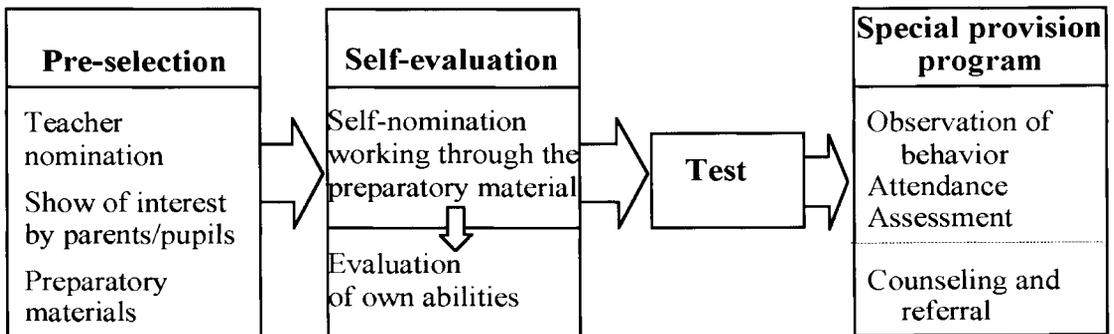

Figure 3. Identification by pre-selection, self-evaluation, testing, and special provision in advanced courses

ness (University of Hamburg) respectively, can be regarded as representing contrasting basic types of provision, and serve to demonstrate the variety of programs around the world.

Talent searches are conducted by the *Center for Talented Youth* (CTY) using the *College Board Scholastic Aptitude Test* (SAT), a standardized test for 17 to 18-year-olds. The idea underlying the search is that “12 to 13-year-olds who score highly on the SAT-M have enhanced problem translation ability and are superior in their ability to represent and manipulate information in short term memory” (Benbow, 1990, p. 96). The Center offers fast-paced mathematics classes during summers in intensive three-week residential courses for students who scored at or above a cutoff score on the SAT-M. Participants registered in, for example, the Precalculus Mathematics Sequence are then given an Algebra Diagnostic Test in order to place them at an appropriate instructional starting point. In accordance with the principle of diagnostic testing followed by prescribed instruction, the students’ approach is tailored to their individual needs (for details of the DT→PI model see Stanley, 1978, 1991; Lupkowski et al., 1990). Progress in course work is paced according to the learners’ unique intellectual talents and motivation. The rationale of the approach is to support young mathematically gifted pupils in the swift and improved mastery of concepts within the conventional maths curricula in a manner that would not otherwise be possible in most public or private school instruction. CTY students use their academic program coursework for credit or placement at their local school (Barnett & Corazza, 1993, p. 56, see also internet sites of IAAY). In this pragmatic approach, mathematical giftedness is above all defined by an extraordinary level of speed in processing and retaining basic mathematical information and in successfully applying this to solving new examples of conventional tasks. Thus, the CTY approach is essentially quantitative in nature: it equates mathematical giftedness with possession of exceptionally large amounts of mathematical knowledge and outstanding success in obtaining correct solutions to conventional problems. Yet, speed components and memory for symbols, numbers and formulae are not considered by mathematicians to be essential for mathematical talent.

The underlying philosophy of mathematics of the *Hamburg Model* (Kießwetter, 1992, 1988) is basically different from the rationale of the CTY. As Wagner and Zimmermann (1986, p. 275) pointed out, the emphasis of the Hamburg Program is on informal mathematics and mathematical ideas rather than on abstract structures. In this way, ‘good mathematics’ is defined by the quality of problem-solving strategies; in this context, mathematics is seen as an open process of thought rather than a universe of fixed products. Therefore, the main educational goal is exploring mathematics by micro-research processes, with as little guidance as

possible; finding and creating problems is, in this view of mathematical provision, of greater or at least equal importance to solving them.

The different basic positions of these two approaches are obvious: while the CTY approach intends to speed up learning, a rather radical form of fast-paced learning of prescribed contents, aided by skilled mentors, the Hamburg approach is guided by the central thought of improving mathematical abilities through working with (for the students in question) new kinds of relatively complex problems.

Four prototypical strategies more or less cover the full range of approaches to fostering mathematical talent: the two outlined above plus *Mathematics Olympics* and *student clubs*. This section will end by presenting a brief overview of the ways in which these strategies differ from each other.

#### (1) Acceleration/Self-Pacing

- Course contents are clearly structured and oriented to the regular syllabus. They are hierarchically organized.
- Participation is highly selective. Admission is by means of tests; a high score on a standardized abilities test is required. In addition to a diagnostic test for selecting a course with an appropriate level of difficulty, achievement tests are used to decide how much credit is to be given.
- The central motives for participating are exposing oneself to a challenge, saving time, and avoiding periods of stagnation in which nothing new is learned.
- Successful implementation of this strategy is dependent upon a readiness on the part of the society to give due recognition to individual effort.

#### (2) Enrichment/Open Syllabus

- Contents are usually taken from areas that are not covered in conventional classroom instruction. They are broad and open, e.g. ‘Applied Algebra’, ‘Mathematics and Music’, or ‘Probability and Statistics’, and are intended to awaken students’ curiosity.
- Participation is selective to highly selective, and is dependent upon passing an entry exam. Further tests have no point. The duration of participation is determined by the opportunities available and the students’ needs.
- Motivation arises principally from interest in the discipline, the expectation of being confronted by challenging material, and the chance to work with people with similar interests.
- Successful implementation of this strategy is dependent upon an intrinsic interest in the subject.

#### (3) Mathematics Olympics

- Courses with the specific goal of preparing students to participate in these international competitions are,

naturally, particularly clearly oriented towards the goal of doing as well as possible in comparison with competitors from other countries. Contents are usually based on areas and topics that have appeared in previous competitions. In other words, the contents are determined by the contest.

- Participation is extremely selective and is usually decided by success in preliminary competitions, for instance in regional elimination contests.
- The reasons why participants expose themselves to the risks of such competitions are undoubtedly complex: in addition to the motivation provided by prizes and other rewards for the winners, they probably include the desire to prove oneself and to obtain prestige. In all probability, motivation is rather extrinsic.
- The degree to which special efforts are made to encourage broad participation in national contests depends upon the political climate in each particular country.

#### (4) Mathematics Student Clubs

- The contents that seize the interest of the participants and hold it over a certain timespan are usually unstructured, as are the groups themselves, that form to pursue a common activity.
- Participation is determined by interest, and depends in the first instance on whether the expectations that led initially to joining up are satisfied. The decisive characteristic of participants is, almost without exception, an interest in the subject and, conceivably, a 'personal disposition'.

### Concluding Remarks

Participation in a special program whether on the basis of high test scores in a talent search, exceptional achievement in the classroom, or by virtue of expressing a strong interest in mathematical subjects and thought processes has unmistakable consequences for the individual's further development. As Eccles and her colleagues have shown in their General Model of Achievement Choice (Eccles, 1985; Eccles & Jacobs, 1986), dynamic processes set off by participation in challenging activities within a subject can have a significant bearing on how such activity is experienced subjectively and the way ensuing decisions concerning career paths are made (see the earlier discussion of gender differences in mathematical achievement).

Taking part in a special program for the mathematically gifted and experiencing the challenge that is inherent in such participation causes change not only in the cognitive structure of knowledge and thought of the young person, i.e. heightened mathematical competence, but also induces change in non-cognitive structure. Up to the present, only modest empirical contributions on these dynamics can be found in studies concerning the effects of such changes. Con-

cepts of the characteristics and components of mathematical giftedness mark the beginning and remain central to any effort to identify and nurture the mathematically highly able. Not only the selection process, but also concepts dealing with the form and content of what optimally should be included in a program are directly affected by assumptions made about the structure of mathematical giftedness. Assumptions which are implicitly presented to schoolchildren assist them in forming their 'perception of mathematics', their subjective realities, which presumably later influence their attitude toward the subject. Special provision for highly able students of mathematics may implicitly induce, as knowledge and mathematical competence increase, a continuous change toward a specific mathematical cast of mind (Krutetskii, 1976). In most programs, this aspect is not explicitly considered.

The variety of approaches that can be used to nurture talent is enormous. The multiplicity of organisational principles, course contents, formal as well as informal settings, regional and national set-ups within the gamut of special provision concepts makes clear that a large number of program forms exist. When selecting or constructing a program from such a large variety of possibilities, the main issue is not that of finding the 'right' one, but of finding the one that is most stimulating for particular participants. All strategies aimed at nurturing mathematical giftedness have their own specific goals and contents, and, as Gallagher (1985) pointed out, they all have their own intrinsic value.

# Talent Development in Science and Technology

Michael C. Pyryt<sup>1</sup>

## Overview

The purpose of this chapter is to discuss effective strategies and programs for developing talent in science and technology. It is organized in five broad sections. The first deals with the development of scientific talent over the lifespan; the second section describes several approaches for discovering talent in science; the third highlights a variety of curricular approaches for developing talent in science; the fourth discusses continual challenges impacting the development of scientific talent. Finally, the chapter provides directions for the future.

## Scientific Development: A Life-Span Approach

The basic tenet underlying this chapter is that the process of talent development in science mirrors the process of career development of scientists; by understanding how individuals become successful scientists, we gain insight into the individual and environmental dynamics that facilitate talent development in science. Piirto (1999) views talent development as a multi-faceted phenomenon in which the genetic attributes, personality traits, cognitive capacities, influenced by the home, school and community coalesce into a vocation. Albert (1980) proposed that two transformations are necessary to achieve eminence. The first involves channeling intellectual giftedness into creative giftedness and the second involves channeling creativeness into the configuration of talent, drive, and values that it takes to succeed. These transformations are viewed as occurring as a result of the dynamic interaction of early talent recognition, family socialization experiences and career development experiences. This interaction is most likely to occur when the particular talent is of special interest to the family.

The Development of Talent Research Project at The University of Chicago (Bloom, 1985) provides insights into the socialization factors that promote talent development. Sosniak (1985) described the developmental precursors of commitment to science for a

sample of outstanding research neurologists. Their parents who provided intellectual stimulation and high expectations actively nurtured the initial curiosity of these potential scientists; they often purchased science kits or toy microscopes, which were used by these future scientists to conduct experiments at home. As they grew older, their experiments grew in complexity; their commitment to research as a career was crystallized by their introduction to formal research in prestigious universities and medical schools.

They chose neurology as an area of study because of its intellectual challenge, complexity, and importance. Sosniak (1999) views the main ingredients of talent development to be time commitment, engagement in authentic tasks, and involvement with communities of like-minded committed individuals.

As one pursues a career there are 'Matthew Effects' (Merton, 1968) or cumulative advantages that accrue from any initial advantage that an individual might have; potential scientists who matriculate at elite undergraduate institutions often have the opportunity to pursue post-baccalaureate study at elite graduate institutions. Five universities (Columbia, Harvard, Johns Hopkins, Princeton, and the University of California at Berkeley) produced over half of the American Nobel Laureates in science (Zuckerman, 1977). After finishing graduate school, laureates were most likely to begin employment or pursue post-doctoral training at prestigious institutions; as part of their training, laureates were likely to have had at least one Nobel Laureate as supervisor or senior collaborator. Potential laureates were socialized to attempt important problems, to appreciate elegant solutions, to maintain high standards of performance, and to work hard to achieve these standards. This work pattern initiated early publication of significant research and subsequent recognition among peers and academic promotions.

The research of MacKinnon and associates at The University of California at Berkeley (MacKinnon, 1962, 1965, 1975; 1978; Barron, 1963, 1969; Helson & Crutchfield, 1970) is the basis for our understanding of the personality characteristics of eminent individuals in a variety of domains, including mathematics and science. Eminent individuals possess the unique com-

<sup>1</sup> University of Calgary, Centre for Gifted Education, Calgary, Alberta, Canada. E-mail: mpyryt@ucalgary.ca

bination of theoretical and aesthetic values because they are motivated to find elegant solutions to discovering the truth; they possess ego-strength and are capable of tolerating ambiguity and disharmony to a greater extent than most people. They are curious and prefer novelty and complexity; typical self-descriptive adjectives of eminent individuals include individualistic, self-reliant, spontaneous, flexible, assertive, ambitious, competitive, and self-confident. Research by MacKinnon (1962) indicates that a certain level of intelligence, typically one standard deviation above the mean, is necessary for creative achievement; once this threshold is reached, intelligence and creativity are uncorrelated. In addition to this threshold effect, the distribution of productivity in domains is skewed (Simonton, 1997); eminent individuals are highly productive individuals, whose output dramatically surpasses the average contributor in a domain.

Heller's (1993) review of the literature on scientific ability makes accessible some important studies from Germany. The five highest effect sizes in a 17 year longitudinal comparison of over 3500 high and average achievements in science and technology were motivation and ability to solve problems (0.71), desire to influence, initiative, and leadership success (0.62), search for knowledge (0.43), early upbringing focusing on independence (0.42), and self-evaluation of school performance in the last three years at school (0.35).

### Discovering Talent in Science

This section highlights a variety of approaches for discovering talent in science and technology: cognitive and affective approaches, profile approaches, and invitational approaches; one of the challenges in developing any identification procedure is to differentiate potential and performance. Students in elementary schools have limited potential to explore scientific content; measures of science knowledge and competencies would be inappropriate. Predictors of science achievement such as mathematics ability would be useful for identifying potential; once the opportunity for learning science content and process is provided measures of science achievement would be more direct measures of developed science ability than indirect measures such as mathematical ability.

The pioneering work of Julian Stanley (1976, 1996; Stanley, Keating & Fox, 1974) through the founding of the Study of Mathematically Precocious Youth (SMPY), originally known as the Study of Mathematically and Scientifically Precocious Youth in 1971, has greatly influenced our thinking about the discovery of mathematical and scientific talent. SMPY uses a talent search approach (Cohn, 1991; Stanley, 1976; Assouline & Lupkowski-Shoplik, 1997; Olszewski-Kubilius, 1998) to identify superior mathematical reasoners. Seventh graders who score at the 97th percentile (national norms) on a standardized achievement test

are invited to take a more difficult test (the Scholastic Aptitude Test). Seventh grade students scoring higher than the average university-bound high school senior on the SATs are given opportunities to participate in a wide variety of educational experiences. Currently regional talent searches for junior high school students using either the SAT or ACT are conducted throughout the United States via the Institute for the Academic Advancement of Youth (IAAY) at The Johns Hopkins University, the Talent Identification Program (TIP) at Duke University, the Center for Talent Development (CTD) at Northwestern University or the Rocky Mountain Talent Search at the University of Denver. Through its international talent searches, The Johns Hopkins University provides the opportunity for students throughout the world to determine their developed verbal and mathematical ability. A new development is the administration of talent searches at the elementary level. The Belin Elementary School Talent Search (BESTS) conducted by the Belin-Blank Center at The University of Iowa administers a test called EXPLORE, a standardized test for eight graders to fourth, fifth, and sixth graders. The EXPLORE test has a science reasoning subtest which requires the test taker to evaluate scientific information and design experiments. The BESTS approach has been successfully imported to Australia and Canada (Assouline, Colangelo, Gross & Pyryt, 1999); talent searches at the elementary school level are also conducted by IAAY, CTD, and TIP.

In addition to mathematical ability, it might also be useful to assess spatial visualization ability. Humphreys & Lubinski (1996) reanalyzed Project Talent (Flanagan et al., 1962) data using canonical correlation and showed that spatial ability in addition to mathematics ability is useful in predicting graduate majors in science and engineering. Spatial-visualization ability is one of the broad factors identified by Carroll (1993) in his monumental factor analytic survey of 476 datasets dealing with human cognitive abilities.

In addition to assessing cognitive components, it is important to address affective dimensions, particularly motivation and interests; among the various conceptions of giftedness (Sternberg & Davidson, 1986), motivation is a common ingredient. In Tannenbaum's (1986) psychosocial model of giftedness, motivation to achieve is one of the non-intellective factors; task commitment is a major component of Renzulli's (1986) three-ring conception of giftedness. Feldhusen (1986) also includes motivation in his conception of giftedness; Haensly, Reynolds & Nash (1986) incorporate motivation in their focus on commitment; Stanley & Benbow (1986) include motivation in their recommendations for talent development in mathematics. Despite its importance in conceptions of giftedness, domain specific measures of motivation are lacking; interviews and observations seem to be the best way to assess motivation for specific areas like science and

technology. Holland's (1973) theory of vocational choice provides a mechanism for assessing interests related to science and science activities; this theory suggests that occupations can be classified by the personality types involved in the occupations. Holland's system classifies occupations as a combination of three of six ideal personality types (realistic, investigative, artistic, social, enterprising, and conventional). Investigative types who prefer occupations that permit searching for the truth dominate science. A variety of career interest inventories such as the *Vocational Preference Inventory* (Holland, 1978), the *Self-Directed Search* (Holland, 1974) or *Strong Interest Inventory* (Hansen & Campbell, 1985) can be used to determine the investigative interests of adolescents.

Rather than using scores on cognitive and affective measures as criteria for selection into specialized programs for talent development in science and technology, it is possible to evaluate potential in science through a profile analysis; Renzulli & Reis (1997) use the Total Talent Portfolio in their School-wide Enrichment Model. In addition to standardized and teacher-made tests, the portfolio includes grades, teacher ratings, products, level of participation, and interaction with others as indicators of maximum performance. The Total Talent Portfolio includes interests in Physical Science, Life Science, Mathematical/Logical and Computers as science and technology related interest clusters. The Talent Portfolio also includes a wide variety of preferences (learning styles, thinking styles, instructional styles, and expression styles) to gain a wholistic picture of a child's needs. Treffinger's (1986) Individualized Programming Planning Model (IPPM) also uses profile analysis in determining needs.

The use of competitions, such as science contests and olympiads provide the opportunity for scientifically talented students to demonstrate their ability in science and technology; these invitational practices permit the opportunity for self-selection since students' participation is voluntary. One of the most prestigious scientific competitions in the United States is the Westinghouse Science Talent Search (Berger, 1994); this competition, now sponsored by Intel, has been in operation since 1942. Each year high school students submit 1000 word research summaries reporting results of an original research investigation; from these submitted reports, 300 are selected as honors recipients and forty participants are designated as semi-finalists and interviewed to compete for 10 positions as Westinghouse finalists. Winners in the talent search have gone on to win Nobel prizes, become MacArthur fellows, and earn election in the National Academy of Science. Subotnik (1986, 1988a, 1988b, Subotnik & Steiner, 1994) is conducting a longitudinal study of a sample of 146 combined honors, semi-finalists and finalists in the 1983 Westinghouse Talent Search. She reported that many of the participants (61%) were

assisted in problem selection by laboratory supervisors and professors. Much of the work was carried out in laboratories in hospitals and universities with practicing scientists serving a mentoring function; subjects tended to attribute curiosity as the major motivating reason for conducting research. Olympiad programs also capitalize on self-selection since individuals typically try out for olympiad teams.

### Curricular Approaches to Talent Development in Science

This section highlights curricular approaches to talent development in science and technology. In addition to three main approaches to gifted education curriculum (content-based, process/product research based, and epistemological concept) identified by VanTassel-Baska (1994), this section also includes a description of community-based approaches and highlights the power of the internet for stimulating scientific activity. Since there are numerous content-based approaches that have been proven effective, content-based approaches will predominate; exemplary models such as specialized schools will combine several approaches.

Content-based approaches focus on the importance on content acquisition as a precursor to scientific productivity; as exemplified by the Study of Mathematically Precocious Youth, the goal is to provide educational experiences that enable talented and motivated youth to master the content of various science disciplines. Over the past quarter century SMPY has pioneered a variety of content-based approaches including DT-PI, accelerated courses, and opportunities for university coursework; it has also supported specialized classes and schools that provide a content-rich experience.

Diagnostic Testing-Prescriptive Instruction (DT-PI) enables students to master content rapidly by concentrating on those skills that students still need to acquire (Stanley, 1978, 1998); this instructional approach involves performing an error analysis of items missed on a given standardized test to determine instructional needs. An instructional program is designed and implemented to address these needs; students are retested on a parallel form of the initial test to determine mastery; if the course content is mastered, students proceed to the next content level using the same approach (Benbow, 1986). Stanley (1998) suggests that computer programs can be used to facilitate the diagnostic testing-prescriptive instruction process. Followers of Renzulli implement a variant of the DT-PI approach when they use curriculum compacting (Renzulli, Smith & Reis, 1982; Starko, 1986; Reis, Burns & Renzulli, 1992).

SMPY has also pioneered the use of fast-paced classes in science (Mezynski, Stanley & McCoart, 1983; Stanley & Stanley, 1986; Lynch, 1990) and mathematics (George & Denham, 1976; Bartkovich &

George, 1980). In these classes, students learn content far more rapidly than in traditionally-paced approaches; Stanley & Stanley (1986) described the use of the fast-paced class approach in science instruction implemented in 1982. During an intense three-week summer institute, students ages 11–15, who scored at least 500 on the mathematics section of the Scholastic Aptitude Test (SAT) and at least 930 on the combined mathematics and verbal sections of the SAT before age 13, learned the equivalent of a year of high school biology or a year of high school chemistry; four students studied both subjects in six weeks. The biology class met approximately 5.5 hours a day including laboratory instruction for 15 days. Pretesting of students, *who had not taken a course called biology*, on the biology achievement test developed by the College Entrance Examination Board (CEEB) indicated that the 25 students in the class earned scores ranging from 420 to 690. The median score of 560 placed the sample at the 52nd percentile. At the end of the three-week course, which was taught by a well-qualified and enthusiastic instructor, knowledgeable about biology content at the high school and college levels, scores on an alternate form of the CEEB Biology Achievement Test ranged from 590 to 800 (the maximum possible score). The median score of 727 placed the group at the 95th percentile on National norms. The 13 students enrolled in the chemistry course earned a median score of 743 (95th percentile) on the CEEB Chemistry Achievement Test; as a result of this initial success, a fast-paced physics course was also developed. Lynch (1990) provided results from fast-paced science classes conducted between 1982 and 1987. Mean post-test scores on CEEB achievement tests were 627 for 353 students in biology, 630 for 339 students in chemistry, and 644 for 213 students in physics; these mean scores represent the 73rd, 67th, and 70th percentiles in biology, chemistry, and physics respectively.

Earning credit by examination through the Advanced Placement Program (Advanced Placement Program, 1994; Hanson, 1980) is a viable way to accelerate one's progress in science and technology; students can earn college credit by receiving a specified score on an Advanced Placement examination. In the area of science, there are examinations in general biology, general chemistry, magnetism, physics, physics/mechanics, and physics/electricity; there are also two computer science examinations. Approximately 1400 colleges and universities award sophomore standing to students who earn satisfactory examination scores on enough (typically 3) AP examinations. Since tuition fees at elite universities in the United States continues to escalate, the ability to pass several AP examinations will result in significant financial benefits for the student.

The Advanced Placement Program distributes course descriptions of the objectives that will be assessed on

the AP examinations; approximately 11,000 high schools offer Advanced Placement courses that address content assessed on the AP examinations. Some universities offer AP Summer Teaching Institutes to prepare secondary school teachers to instruct specific AP courses; fast-paced classes can be geared to AP examinations (Mezynski, Stanley & McCoart, 1983). SMPY implemented courses in physics and chemistry that were taught by college professors to students ages 12 to 17. Seven of the ten students, who completed the physics earned a grade of 3 or higher on both the mechanics and electricity and magnetism sections of the AP Physics: C examination; three students earned a grade of 2 on both sections of the AP Physics:C examination. Eighteen students completed the chemistry course. Twelve of the 14 students who took the AP Chemistry examination earned a grade of '3' or higher; homework performance, in-class test scores, and AP practice test scores were predictive of Advanced Placement Examination scores. Longitudinal studies have indicated that AP students are more likely than non-AP students to select an academic or scientific career, graduate early, and apply to selective colleges (Advanced Placement Program, 1994). Brody, Assouline & Stanley (1990) found that the number of Advanced Placement credits was the only statistically significant predictor of first semester GPA, cumulative GPA, percentage of semesters on the Dean's List, and honors at graduation in their study of early entrants at Johns Hopkins.

SMPY has also pioneered the notion of content acquisition through early university coursework either on a part-time or full-time basis. Solano & George (1976) examined the university achievement of 131 adolescents identified by SMPY; overall grade point average on a 4-point scale after taking 277 college courses was 3.59. The majority of these courses were in the areas of mathematics and the natural sciences. Early admission to college (two years earlier than normal) is a possible option for some highly able and motivated students. SMPY's first radical accelerant entered The Johns Hopkins University at age 13 and completed the requirements for a B.A. degree in quantitative studies and an M.S. in Engineering specializing in Computer Science at age seventeen years and ten months (Stanley, 1974). He went on to earn a Ph.D. in computer science from Cornell University and is currently a professor at Carnegie Mellon University (Hendricks, 1997). Stanley & McGill (1986) correlated demographic variables (age, gender, SMPY affiliation, credits at college entrance, attendance at private high schools, Oriental parentage) and indices of college performance (age at graduation, number of credits earned, simultaneously earning Bachelor's and Master's degrees, percentage of time on the Dean's List, cumulative GPA, Honors at graduation) for 25 students who entered The Johns Hopkins University two-to-five-years earlier than usual. They

reported two significant canonical correlations of 0.87 and 0.78 between composites of demographic variables and outcomes. Further analysis indicated that SMPY affiliation, credits at college entrance and attendance at private schools were most related to Honors at graduation, cumulative Grade Point Average, age at graduation, and number of credits earned. Brody, Assouline & Stanley (1990) expanded Stanley & McGill's (1986) study to include 65 students, who entered Johns Hopkins between the ages of 13 years 8 months and 17 years 7 months. Accelerants were more likely than non-accelerants to simultaneously earn bachelor's and master's degrees, win general honors and departmental honors at graduation, and be elected to honor societies such as Phi Beta Kappa or Tau Beta Pi, the national engineering honor society. Hendricks (1997) describes a twenty-year follow-up of some of SMPY's initial early entrance group; for the most part, the early entrants have successful careers and have benefited greatly by their acceleration experience. Brody & Benbow (1987) examined the effectiveness of the smorgasbord of educationally accelerative opportunities model. Students who made use of accelerative options attended more selective colleges, had higher college GPAs, won more honors, and had higher career aspirations than students who decided against making use of these accelerative options.

The SMPY model has been replicated throughout the United States. Other Universities operating projects based on the SMPY model include: The University of Washington, Northwestern University, Duke University, Arizona State University, University of Denver, Iowa State University, the University of North Texas, Purdue University, Sacramento State University, and the University of Wisconsin in Eau Claire (Stanley, 1991a). The SMPY model has also been successfully implemented in China (Stanley, Huang & Zhu, 1986).

There are various models of specialized schools for students who show promise for achievements in science and technology. Stephens (1998/1999) described the 11 state-supported residential mathematics and science high schools in the United States with a total enrollment of 3,366 students. Models differ primarily in the initial age at entry, length of experience, degree of acceleration permitted, and the amount of university-level experiences provided. Entry to selective residential programs is typically based on performance on examinations or through participation in regional or national science olympiads; the majority of the faculty hold advanced degrees. Students graduating from these residential high schools receive scholarship offers from prestigious universities.

Stanley (1987) advocated that three-year state residential high schools for science and mathematics be established for all states having at least 300 National Merit semi-finalists each year. He recommended identification in terms of established minimum scores on the Scholastic Aptitude Test, performance on measures

of non-verbal reasoning ability, mechanical comprehension, spatial visualization, and knowledge of science and mathematics, demonstrated interest through participation in science fairs and contests, and recommendations by science and mathematics teacher. Faculty qualifications would include at least a master's degree in the subject area taught and successful experience as Advanced Placement teachers. The goal of the curriculum would be to facilitate successful performance on the Advanced Placement examinations in biology, chemistry, physics, computer science, and calculus; proximity to a college campus, would enable students to take college level courses; participation in prestigious competitions such as the Westinghouse Science Talent Search would be strongly encouraged. Aspects of Stanley's (1987) vision has been realized with the establishment of the Texas Academy of Mathematics and Science (TAMS), which is located on the campus of the University of North Texas in Denton, Texas (Stanley, 1991b). Scores of at least 550 on the mathematics section of the Scholastic Aptitude Test and combined scores of at least 1000 on the mathematics and verbal sections of the SAT are minimum entrance requirements for entering eleventh grade students. Students are required to complete at least 57 semester hours of university courses consisting of two semesters each of biology, chemistry, physics, and calculus; 24 semester hours of English, humanities, and social science; and additional electives to earn their high school diploma. Students who complete TAMS can matriculate as juniors at institutions of higher education in Texas or throughout the United States. The TAMS model is cost-effective because the use of college professors and university facilities saves the typical capital expenses of school buildings with science laboratories and dormitories as well as personnel expenses. The residential aspect of TAMS also promotes social interaction. Another model for state-wide residential high schools is the North Carolina School for Science and Mathematics (NCSSM), which was established in 1980 and located on a 27-acre campus in Durham, Carolina (Eilber, 1987; Eilber & Warsaw, 1988). The NCSSM also enrolls eleventh and twelfth graders; admission is determined through a two-step process. The first step involves rating a selection portfolio consisting of scores on the mathematics and verbal sections of the SAT taken in tenth grade, scores on a non-verbal test of critical thinking, grades in maths and science in grades 9 and 10, ratings on a teacher checklist, student essays, and recommendations. The second step involves selecting students based on interviews of students with promising selection portfolios. There are 20 possible courses in mathematics and computer science, 16 courses in biology, 8 courses in chemistry, and 8 courses in physics at NCSSM. Student requirements include: at least one course in biology, chemistry and physics; two years of English courses which emphasize writing;

choice of Spanish, French, German, Russian, Latin, or Chinese as Foreign Language; and American History. Courses in social science, music, visual arts, and interdisciplinary courses are taken as electives. Although the content is advanced, the courses are not designed to ensure success on Advanced Placement examinations. Students are given opportunities to conduct research at NCSSM facilities or participate in yearlong mentorships with researchers and professionals in the Durham-Raleigh-Chapel Hill area. Students are also required to perform three hours of work service each week during their stay at NCSSM and 60 hours of community service work in their home communities during the summer following their junior year. The NCSSM offers workshops each summer for secondary teachers in science and mathematics and coordinates summer research and laboratory-oriented courses held for eleventh and twelfth graders throughout the state of North Carolina. About two thirds of the graduates enter universities in North Carolina and about a third enter selective universities elsewhere; a follow-up study of the graduating class of 1986 indicated that most (80%) were pursuing a career in science or mathematics.

Specialized schools for those talented in science and technology have been described by Pyryt, Masharov & Feng (1993). The development and establishment of an exciting residential school in Israel has been described by Amram (1999); the Israeli Arts and Sciences Academy brings together students with talents in the arts and sciences from throughout Israel. In addition to project-oriented content in the sciences and humanities, students participate in a variety of community service activities. The Israeli Arts and Sciences Academy also runs a Discovery Program to facilitate the educational development of economically disadvantaged students.

Non-residential specialized high schools for the scientifically gifted can be successfully implemented in large urban centers. For over 50 years, the Bronx High School of Science has been developing the scientific talents of students in New York City (Taffel, 1987; Kopelman, Galasso & Schmuckler, 1988). Performance on an entrance examination, consisting of language aptitude and mathematics aptitude and reasoning, is used to select 1000 students from a pool of 4000 applicants. (The school has recently instituted a special program to admit minority and disadvantaged students based on examination performance, feeder school nomination, and completion of an intensive summer program in English and mathematics). The core curricular requirements include: four years of English, four years of social studies, four years of science including biology, chemistry, and physics, three years of a foreign language, three years of mathematics, one year of mechanical drawing, one-half year of shop experience. Two advanced electives from among courses in science, mathematics, computer

science, and advanced scientific laboratory techniques are required; courses in computer literacy, music, art, health education and hygiene are also required. A unique aspect of the science curriculum is the use of block scheduling, whereby students have two consecutive science periods each day permitting more intensive exposure to scientific content and integration of classroom discussions and laboratory experiences. Students are encouraged to do independent research in mathematics and science; they are mentored by the teaching staff at Bronx High School of Science and volunteer scientists from universities, laboratories, hospitals, museums, zoos, and botanical gardens in New York City. Students are expected to communicate the results of their research by writing research reports and submitting them to various competitions such as the New York City and New York State Science Fairs, and the Westinghouse Science Talent Search. The school also publishes annual journals highlighting the best research in mathematics, biology, and physical sciences.

Data reported by Berger (1994) indicates that the number of finalists in the Westinghouse Talent Search from the Bronx High School of Science (118), as of 1990, was more than double every other high school in the United States, with one exception, Stuyvesant High School, another specialized school in New York City, which had 70 winners. Over a 50-year period, about 65% of the graduates of the Bronx High School of Science have become scientists.

Successful programs can also be offered in non-specialized schools; the pioneering work of Brandwein (1955, 1962, 1981, 1986 1988, 1992) at Forest Hills High School in New York City provides insights into how schools can organize science programs to challenge scientifically gifted students. In contrast to the previous programs described, no tests are given; students are given the opportunity to conduct independent research. Brandwein suggested that three clusters of traits called genetic, predisposing, and activating are necessary for developing scientific talent. Genetic factors are the mathematical and verbal aptitudes that a student brings to the situation; these abilities contribute to the acquisition of scientific knowledge and the communication of the results of scientific investigations. Predisposing factors are motivational traits and include the student's persistence and questioning attitude; activating factors relate to the school climate and environment variables that facilitate scientific development. Some of the components of the specialized curriculum in science pioneered by Brandwein include: conducting original research, learning laboratory techniques and the use of laboratory equipment; engaging in library research; taking adequate preparation in mathematics, preparing research reports and exhibits, participating in seminars and conferences, entering the Westinghouse Science Talent Search, and taking college-level courses. The model developed at

Forest Hills High School has been successful in developing scientific talent as evidenced by the success of its students in the Westinghouse Talent Search. Forest Hills ranks third among high schools in the United States in producing the number of finalists (42) in this prestigious competition (Berger, 1994).

The process product approach focuses on the incorporation of the scientific method into projects aimed to produce knowledge; the research component of the specialized high schools and the products submitted to the Science Talent Search are exemplars of this approach. In gifted education, Renzulli's original enrichment triad model (Renzulli, 1977) and current schoolwide enrichment model (Renzulli & Reis, 1997) provided the opportunities to apply the research method to the individual and small group investigations that comprise Type III enrichment. Renzulli & Reis (1997) describe a Type III science project, entitled 'Bobby Bones', which is a life-sized model of the human skeletal structure.

The National Curriculum Science Project at the Center for Gifted Education at the College of William & Mary has produced a problem-based science curriculum that uses real problems to integrate science concepts, process, and systems (Center for Gifted Education, 1997). The curriculum includes units on topics such as pollution, nuclear waste, electricity, and acid spills. Evaluation data has supported the effectiveness of the William & Mary units for developing science process skills.

Thematic units are another way to integrate science content and processes into the curriculum. VanTassel-Baska (1994) classifies this approach as the epistemological concept model, since it focuses on how we come to understand knowledge and uses Hayes-Jacobs and Borland's (1986) interdisciplinary concept model as an exemplar for this approach. The exploration of concepts from an interdisciplinary perspective permits the student talented in science and technology to solve science-related problems for a theme. For example, using the theme, 'flying', a student with an interest in science might examine the physics of flight.

There are a variety of worthwhile opportunities for students interested in learning more about science; Passow (1988a) highlighted some programs available for high-ability pre-college students. These included programs offered by prestigious universities such as Johns Hopkins and Columbia; conducted by national laboratories such as the Argonne National Laboratory (Illinois), the Fermi National Accelerator Laboratory (Illinois), the Lawrence Livermore National Laboratory (California), and the Los Alamos National Laboratory (New Mexico); and provided by museums such as the Chicago Museum of Science and Industry. These programs provide opportunities for students to take courses, engage in research, or combine coursework and research; similar opportunities are provided at science centers (Sitkoff, 1988) such as the Talcott

Mountain Science Center in Connecticut (LaSalle, 1979).

The internet has become an invaluable tool for expanding science knowledge. A visit to the National Science Teachers Association website ([www.nsta.org](http://www.nsta.org)) will yield five pages of links covering archeology, astronomy, biology, chemistry, earth and space science, environmental science, general science, geology, mathematics, and physics. Featured articles from science magazines such as *Scientific American* are also available online. The December 1999 featured article by Sir John Maddox ([www.sciam.com](http://www.sciam.com)) suggests that the discoveries of the next 50 years will begin with our cataloguing of our current ignorance; the article has numerous links related to the history of science. Government agencies such as the National Aeronautical and Space Administration have developed a wide variety of science-related resources for educators, students, and the community (<http://education.nasa.gov>). The NSTA museum link has connections to general and specialized science museums in the United States, Canada, Italy, Sweden, and Singapore. The Study of Exceptional Talent at The Johns Hopkins University ([www.jhu.edu/~gifted/set](http://www.jhu.edu/~gifted/set)) has an extensive set of links to scientific competitions such as the Science Talent Search ([www.sciserv.org/sts](http://www.sciserv.org/sts)).

### Continual Challenges in Developing Science Talent

There are several continual challenges that affect the talent development process in science. The first is the continual differential performance of males and females and differential persistence in science careers; the next is the need for science education to address the ethical dimensions of science; the third continual challenge is the development of teacher/mentors who can appropriately challenge students talented in science and technology.

Since the initiation of talent searches, gender differences in mathematics performance on the Scholastic Aptitude tests have been rampant (Stanley, Keating & Fox, 1974). Stanley, Benbow, Brody, Dauber & Lupkowski, (1992) found dramatic gender differences on a wide-variety of high-level cognitive tests. These differences are correlated with values and career interests (Fox, Pasternack & Peiser, 1976; Fox, Brody & Tobin, 1980; Lubinski, Benbow & Sanders, 1993). Longitudinal studies (Subotnik & Arnold, 1994, 1996) highlight the dilemma that gifted professionals face as they try to balance career and family issues. Several models have been proposed to understand the nature of differential scientific achievement paths of males and females (Eccles & Harold, 1992; Benbow & Lubinski, 1993a, 1993b; Noble, Subotnik & Arnold, 1996; Reis, 1996). These models have much in common and focus on how the combination of individual cognitive and personality traits interact with socialization factors and in producing career paths consistent with one's interests and value patterns; they

highlight the importance of mentors and role models. Mentorship experiences give students the opportunity to learn the nature of the discipline by personal interaction with practicing professionals. Through such experiences, individuals are socialized into the cognitive processes scientists use as well as their work habits, attitudes, and values. Exposure to appropriate role models seems especially critical for scientifically gifted females (Tobin & Fox, 1980).

There is also a need for the science curriculum to address the ethical dilemmas that scientists face (Passow, 1957, 1988b; Pyryt, 1979; Tannenbaum, 1979; Frazer & Kornhauser, 1986). This need has been stated most eloquently by Tannenbaum (1979), who quotes Commoner's (1966) dictum that "no scientific principle can tell us how to make the choice, which may sometimes be forced upon us by the insecticide problem between the shade of the elm tree and the song of the robin" (p. 104). Computer espionage and sabotage through viruses provide another example of the need for gifted individuals to use technology as a productive rather than destructive force.

All of the successful programs for nurturing gifts/talents in science and technology acknowledge the importance of the teacher/mentor. Passow (1957) identified the following characteristics as exemplifying a quality science teacher: he/she is inspired and inspiring; knows science and its techniques; understands the meanings of science and its relationship to the world, encourages individual excellence; guides the student to locate resources; adapts teaching methods to stimulate problem solving; attempts to provide flexible programming to meet the unique needs of rapid learners.

### Directions for Future Research

This chapter summarized important conceptions and research related to the development of science and technology; still, much remains to be done. Various multidimensional models have been proposed to account for development in science and technology and differential achievement patterns of males and females; these models tend to propose numerous interacting variables over a long time span. The models appear to be heuristic and at this stage represent implicit theories (Sternberg & Davidson, 1986) rather than explicit ones. Many of the variables such as self-concept of ability, self-efficacy, and attributions are likely to be highly correlated; models that include measures of all of these constructs may be unnecessarily complex. There is a need for large sample, longitudinal studies using structural equation modeling techniques to determine the most parsimonious models. There is also a need for longitudinal studies that relate the characteristics of young children and adolescents to those of eminent scientists; most studies of eminence in science examine the characteristics of eminent adults after they have achieved acclaim; we need to know more about their

cognitive and affective traits as children. There is also the issue of domain-specificity; more research is needed to determine whether or not the models hold across all science disciplines. If all of the curricular approaches described are beneficial, research is needed on the amount of time that should be dedicated to each approach to maximize science achievement. It is likely that there will be an interaction between a person's cognitive and affective profile and the variety of curricular options needed.

# Promotion of the Gifted in Vocational Training

Rudolf Manstetten<sup>1</sup>

## Introduction

Giftedness is a central research field of psychology and it is also of basic importance for other sciences, especially for educational science which is not only in need of the results of psychological giftedness research, but also has to examine adequate measures in order to promote the gifted. However, in psychology, as well as in educational science *vocational giftedness* has been a research desideratum.

In the following study the promotion of vocationally gifted young people in the fields of business and commerce, crafts and trades and others will be introduced and discussed. The study deals with those young people who have passed their initial vocational training in the German dual system. Academic qualifications will be excluded. The *Promotion of the Gifted in Vocational Training* which started in Germany at the beginning of the nineties, is quite a new phenomenon, contrary to the old dual system of vocational training. The following ideas try to discuss the theoretical models and practical measures of this newly designed promotion program for gifted young people in vocational education.

The young people participating in the program as grant recipients receive 9,000 German marks for a period of three years. The grant is seen as a support for further vocational training. A prerequisite to participate in the program are excellent results in the final examination of initial vocational training. Since 1991 about 3,000 young people have been enrolled in the program yearly. In the meantime nearly 10,000 young people have benefited from this program which is financed by the German Government with 25 million German marks per year.

The program has been scientifically tested since 1991. Three questions were closely studied:

- Which special personal characteristics are shown by the vocationally gifted young people?
- Which training measures did they choose?
- Which effects did the promotion program have on vocational careers?

These research results will be depicted and discussed here. The study is partly related to the research of entire age-groups, and it also includes the analysis of representative samples based upon sociometric tests and interviews. The following findings refer to the most important research results. The complete results are stated in a special report which also includes the applied research methods and statistical analysis (Manstetten, 1996).

## Current Importance of the Research Topic

The program *Promotion of the Gifted in Vocational Training* emphasizes a rather neglected area of giftedness promotion. In Germany and many other countries multiple promotion activities exist in various educational fields such as kindergartens, schools (special classes, etc.), as well as in academical institutes, universities and others. A promotion of giftedness for about 1.5 million young people who spent a non-academic practical vocational training in the dual system of school and company has not yet happened.

This fact is rather surprising because the dual system of vocational training is typical for Germany and is passed by most of the young people between the age of 16 and 19. Furthermore, there are no studies in psychology that deal with the specially gifted in this field; the following sections, therefore, present concepts and preliminary results on this topic. We hope that interest in psychological research of giftedness will be stimulated to undertake further efforts in this research area.

## Historical Importance of the Research Topic

The necessity for the study of *vocational giftedness* and its promotion was already seen at the beginning of the last century. Contributions to the promotion of giftedness of young people in technical, industrial and trade vocations already appeared in a report of Petersen, entitled *The Rise of the Gifted* (Der Aufstieg der Begabten, 1916). The main idea of this report was astonishingly similar to the intention of the program of the German Government 75 years later:

---

<sup>1</sup> University of Osnabrück, Germany.

- (1) "It is economically, socially and ethically necessary to find ways to identify, to evaluate and to promote giftedness better; giftedness means practical giftedness related to the sense of duty and strength of mind.
- (2) The promotion of the gifted has to be carried out in an organized way.
- (3) Promotion of the gifted should not lead to an increase in academic professions; on the contrary, the danger of economic and social over-estimation of the academic professions should be opposed as much as possible and should attempt to reach a more suitable appraisal and appreciation of the practical vocations" (Petersen, 1916, p. 205; translation from German).

Stern (1916, p. 106) asks the German Science in his contribution to this report to prepare for the understanding of intelligence as a national treasure and to utilize this for educational and vocational abilities: Modern psychology should deal with research and diagnosis of giftedness.

Furthermore, Stern also complains that we know very little about the assumed demands of giftedness in commercial, technical and industrial vocations. Therefore, he already urged schools to introduce measures such as lessons in crafts and trades for example, because hidden technical and manual talents would then have the opportunity to come to the surface (Stern, 1916, p. 115).

Until now, these demands for research and promotion of vocational giftedness have mostly remained unfulfilled, although giftedness had been a major point of German pedagogical psychology in the sixties. Research results of that time are reported in the book *Giftedness and Learning* by Roth (Begabung und Lernen, 1969) for example, which influenced sciences and politics of education greatly at that time. With regard to important publications of educational science for the last 20 years, it seems, however, that this topic has nearly disappeared from pedagogical discussion although psychological giftedness research has intensified at the same time. The dispute of this topic is equally missing in vocational educational science as well as in the practice of vocational training. Nevertheless, there was already an approach to promote vocational giftedness in Germany in 1954, but this approach was confined to young craftsmen only who received a prize for their excellent examination results (Schubert, 1958).

### To the Relevance of Models of Giftedness

In order to emphasize specifics of vocational giftedness, the knowledge in the psychological field of giftedness research should be referred to. Because there are numerous definitions, Roth (1969) proposed that each researcher should define his own term of

'giftedness'. Furthermore, totally different terms such as 'talent', 'high talent', 'special giftedness' and others are used in a partly synonymous and partly different way.

Without extending the terms, we shall preliminarily define 'vocational giftedness' as special dispositions which are shown in special achievements of (non-academic) vocational learning and action. In this way, the term 'gifted in vocational training' shall be understood.

Another problem must be seen here if 'giftedness' is explained by the term 'achievement' which also has to be defined. We will not discuss 'achievement' here, but according to Schiefele/Krapp (1975) the terms 'giftedness' and 'achievement' should not be used in the same way. The term 'giftedness' shall be used as a theoretical construct for the explanation of special phenomena such as special achievement, but not for the description of these phenomena. Stern already stressed that "giftedness is only a possibility respectively an imperative prerequisite of achievement, but it does not signify achievement itself" (Stern, 1916, p. 110). Therefore we understand that 'vocational giftedness' should be defined as disposition of abilities that explain observable (vocational) achievements.

The terms 'giftedness', as well as 'achievement' must also be seen in a sociological aspect; this aspect signifies that achievements on their part are determined and evaluated by societal norms (Heid, 1969). Whether a person is gifted or not shall be determined by the way this person shows excellent achievements in relation to a comparative group, whose achievements are evaluated positively by society. The reason that vocational giftedness has not yet been researched and promoted can also be seen as an indicator that vocational achievements have not been evaluated favorably by society.

Giftedness must also be seen in an anthropological aspect. This aspect signifies the question whether giftedness is genetically or environmentally determined. The question whether giftedness is either a matter of innate abilities or social and cultural influences, is not only as old as the research of giftedness itself, but there have not been clear empirical results to answer this question. Psychologists seem to have a more pragmatic understanding which states that both inheritance *and* environment have an interactive effect on the development of giftedness. Since giftedness is no longer seen as a static phenomenon, but a dynamic developmental process—in the interaction of inheritance and environment—the dynamic-interaction approach is consequently preferred.

It seems to be undoubtedly certain that these aspects of giftedness can be regarded as decisive factors for vocational giftedness; much more of a problem is the identification of factors, criteria and components that constitute vocational giftedness. Psychology with its

models of giftedness, can probably help to find basics for this.

Without describing the various models of giftedness in detail, it can be said that giftedness is very often identified with intelligence in pedagogical-psychological references. In contrast, Stern (1916, p. 111) already emphasized "that not intellectual giftedness determines selection, but also the strength of interest and the excellence of will."

There are various complex models in the psychological research of giftedness which describe the factors and components of giftedness in different ways. These can mainly be reduced to the following aspects:

- Which cognitive (e.g. intelligence) and/or non-cognitive factors of personality (e.g. motivation) are essential?
- Are environmental factors included?
- How far are areas—besides sports, arts or sciences—such as trades, commerce, communication, etc. also involved?

As a further category, models should be taken into account that define high-giftedness as achievement and which partly overlap with the already mentioned aspects. According to Sternberg (1993) a person is highly gifted if evident achievements are produced that are—in relation to a comparative group—excellent, rare, productive and valuable.

For further clarification the models of Renzulli (1978, 1986), Gagné (1985, 1993) and the new variant of the Munich model of (high-)giftedness (Heller et al., 1994) shall be introduced briefly, examining how far these models can offer a basis for the explanation of vocational giftedness.

In Renzulli's three-ring conception "giftedness consists of an interaction among three basic clusters of human traits—being above average general abilities, high levels of task commitment and high levels of creativity" (1979, p. 23).

This often cited model is also criticized, however, because Renzulli does not draw a line between *giftedness* and *achievement*; but this differentiation is especially important for the educational field because achievement and not giftedness is measured here. It seems to be possible to draw the conclusion that special achievement indicates special giftedness. Contrary to that it is not possible, however, to infer from low achievement a low giftedness. There are pupils who achieve bad results although they show excellent abilities according to psychological tests; these pupils would not be regarded as gifted in the model of Renzulli. Furthermore, it should be criticized that this model depicts creativity as a constitutive factor for giftedness. Contrary to that, there is the example of a sportsman who is highly gifted, but seldom especially creative (Holling et al., 1996). These examples show that the model of Renzulli is hardly adequate to explain

giftedness sufficiently; therefore it can hardly be used for the description of vocational giftedness.

The *differentiated model of giftedness and talent* is introduced by Gagné (1993) who distinguishes between *giftedness* and *talent*: Genetically determined and not yet developed abilities (giftedness), on the one hand, and systematically developed abilities or expertise in special fields of action (talent), on the other hand, are separated from each other. The development of a special talent is supported by intrapersonal catalysts such as motivation and personality and environmental catalysts as well as learning, training and exercise.

Without returning to this model and the differentiation made between giftedness and talent, which is also controversially discussed in the psychological literature, the following can be stated: On the one hand, there are no exclusively creative or intellectual abilities being used as a basis, as in other models of giftedness, but 'socioaffective' and 'sensorimotor' aptitude domains and others are also named here. Therefore, vocational abilities can also be included. On the other hand, talent is not only related to arts, athletics, sciences and technology, as well as education, but is also related to vocational fields such as business and commerce, crafts and trades, health services, transportation and communication. Concerning vocational giftedness, it is also essential that *learning*, *training* and *practice* in a special field are emphasized in its significance for the development of talent. It has to be pointed out, however, that this model does not differentiate between *giftedness* and *achievement*.

The Munich giftedness model of Heller et al. (1994) does not differentiate between giftedness and talent, as in the Gagné model, but it distinguishes between *giftedness* and *achievement*. The differentiated structure of this concept is quite similar to the Gagné model. Heller et al. point out intellectual and creative, as well as social and sensorimotor factors of giftedness, on the one hand, and technical and social achievements besides sports, mathematics and others, on the other. Therefore, both models can be seen as a basis for giftedness research in non-academic vocations in the field of technics and commerce, crafts and trades, as well as in social vocations. Nevertheless, both models do not sufficiently explain the specific factors of vocational giftedness itself.

According to Mönks (1991) it should also be mentioned that social competences, should be emphasized more as important internal catalysts, because they are particularly significant for the occurrence of excellent achievements. It also has to be mentioned that social competences gain importance in various vocational fields without being especially nurtured in schools.

All in all it has to be criticized that some models are too inadequate to offer a basis for a concept of vocational giftedness; they can hardly explain gifted-

ness at all. This is not only true for one-sided models that are focused on intellectual abilities, but also for those that do not differentiate between giftedness and achievement or which start out from creativity as a constitutive factor (e.g. Renzulli, 1986).

Similar to Gagné, the Munich model of giftedness (Heller et al., 1994) also focuses on a differentiated understanding of giftedness which seems to be suitable for explaining factors of vocational giftedness. Furthermore, *learning*, *training* and *practice* which are stressed by Gagné (1993, p. 72) also seem to be very important for vocational giftedness. He emphasizes abilities, skills and knowledge which were developed at a certain point of time and which are the reason for particularly successful practice of (vocational) activities.

It becomes clear so far that a differentiation between general and vocational giftedness is hardly meaningful because there is no general giftedness as Trost (1991, p. 2) stated. This would only be true if giftedness is seen as intelligence (as a general ability to learn and solve problems). If this is rejected, however, as described at the beginning, giftedness will always be a special giftedness, i.e. "giftedness for special achievements" (Trost, 1991, p. 2). With this it can be stressed that giftedness is not related to a narrowly limited ability (e.g. adding numbers), but always to more complex achievement areas (e.g. commercial giftedness).

If we are not to speak of general giftedness, but of giftedness for special achievements then the question arises how those factors that were confirmed by giftedness research can also be confirmed by vocational giftedness research. In order to preliminarily clarify that question the following results from the scientific research of the promotion program are described and discussed (Manstetten, 1996).

### Evaluation of Current Strategies in Germany

#### *Personal Characteristics*

The empirical results of vocational giftedness research are based upon interviews and sociometrical tests of young employed persons who were selected as grant recipients by the responsible Chambers of Commerce, Trade and others.

Summarizing the research results some considerable differences to previous findings of giftedness research can be depicted. There are, for instance, differences regarding constitutional environmental characteristics in the family and school area (Bals, 1996, p. 324). While previous giftedness research has identified first born and single children as highly gifted this could not be verified by our random sample of grant recipients tested here. It also cannot be confirmed that higher education and social status of parents determine vocational giftedness; the grant recipients mostly come from lower status families. According to the findings, most of these grant recipients see a chance of a

vocational career in their vocational training. That can also be regarded as a reason why these young people show a different profile in their school careers, compared to previous results of giftedness research. There are excellent school achievements in our sample, but more typical are discontinuous curricula vitae showing grave problems (Bals, 1996, p. 324).

Psychometric tests with grant recipients (Holling et al., 1996, p. 109) also show considerable deviations related to factors such as intelligence and creativity which are regarded as basic giftedness factors (e.g. Renzulli). In this respect grant recipients only showed average results. Therefore, these factors, which are controversially discussed, are inadequate for vocational giftedness and cannot explain excellent vocational achievements.

A remarkable consensus about motivational factors is shown by the findings. Compared to test persons of non-grant recipients of the same age group, the grant recipients analyzed here showed stronger work-related interests, more distinct engagement in their occupation and a higher general achievement motivation. A further indicator for high motivation is seen in the strong interest in further education, which is documented in the more intensified use of vocational and non-vocational training measures.

All in all these results indicate that vocational giftedness shows specific characteristics which are partly different from current giftedness research results. A reason for this could be found in the present practice of selecting grant recipients by the Chambers of Commerce, Trade and others.

Grant recipients are selected primarily according to their results in the final examination of initial vocational training; this selection process is not going to be described here. It should be mentioned, however, that this program does not concern promoting young people during their training; examination results are the criteria for their selection, but the examinations only refer to special vocational knowledge and experience; other skills that might be important for a vocational career are not considered.

#### *Promotional Measures*

Contrary to the selection process, which uses functional examination achievements as a criterion, promotion is not only limited to vocational qualifications. Apart from vocational education, general education is supported as well, which can refer to different topics. Grant recipients are offered a broad spectrum of educational possibilities so that they can choose among a wide range from public and private suppliers; young employees have many possibilities which they can use for their individual vocational career chances. The program's objective, therefore, tries to enable young people to see attractive vocational careers as an alternative to studying at the university.

The attraction of vocational education, however, cannot only be improved by financing pretentious measures of further education. The motives for going into further education are manifold, resulting from economic and technological developments, the competition between genders for occupational positions, the increasing internationalization of labor markets etc.

The evaluation of the 3,000 grant recipients enrolled yearly since 1991 draws a reliable and complete picture of further educational interests. About 80% of the grant recipients' choices of courses concentrate on the six categories of the following ranking list:

- (1) technical skills
- (2) foreign languages (mostly English)
- (3) economic knowledge
- (4) information technology (computer)
- (5) management tasks
- (6) communication.

This can be divided into two groups, *specific* (number 1 and 3) and *non-specific* (number 2, 4, 5, and 6) vocational measures.

Apart from foreign languages which were primarily chosen in the first promotion years, the profile of the following promotion years has remained relatively stable; but the career possibilities that are connected with these measures are different. In recent years technical and economic courses have had the highest priority in order to achieve higher vocational levels (e.g. examination for the title of a *master craftsman*), which are less attainable with courses for computing, management and communication. The reason for this is that technical and economic qualifications are directed towards special occupations; the other topics are *non-specific*, i.e. they are related to various vocations. Therefore, the chosen courses indicate different preferences for careers; while some serve vocational advancement directly, others enable a higher vocational qualification that is important for various vocations.

It is interesting that the decision for one of the two groups is related to gender. Female grant recipients mostly chose foreign languages followed by economic courses; technical and information technological courses range significantly lower. Male grant recipients mostly selected technical and information technological courses. This shows that there are specific career plans for young gifted employees according to gender and generally this is typical for the vocational selection process of young people.

Significant for the interests of further education is also the school level already achieved; 30% of all the high school graduates (A-level) chose foreign languages and 20% economic topics, so that 50% of the grant recipients concentrate on only two categories. Contrary to that, nearly 50% of the non-high school graduates (lower than A-level) chose technical and information technological topics.

Also the statistical correlation of analysis showed significant coherence between the variable *topic of further education*, on the one hand, and the variables *gender* and *school grade*, on the other; i.e. foreign languages are mostly chosen by women and high school graduates while men and non-high school graduates prefer technical courses which make it possible to achieve a higher vocational level. Career planning strongly depends on gender and school grade; female grant recipients are obviously less interested in a vocational career than men. High school graduates dislike a career oriented further vocational training more than non-high school graduates.

#### *Career Promotion*

How far can the program *Promotion of the Gifted in Vocational Training* effectively nurture the career of former grant recipients? This question is of foremost interest because the results are also a control for the success and the efficiency of this program.

The first analysis of efficiency was already completed in 1994 (Manstetten, 1996, p. 354; p. 378); it referred to those grant recipients who were enrolled in the promotion program in 1991 and 1992. Positive short-term effects on vocational developments could already be found here.

The second analysis of efficiency, which was carried out in autumn 1997 by Fauser/Schreiber, was aimed at the research of longer term effects of the promotion program (Fauser/Schreiber, 1998). This analysis covers the following two groups of grant recipients annually admitted in various years:

- First there were 1,400 grant recipients admitted in 1991/92. Those grant recipients had already taken part in the research study of 1994.
- Second there were 4,300 grant recipients admitted in 1994.

The questionnaires were answered by 3,093 grant recipients (63%). The benefits of the promotion program for the vocational career of the grant recipients were more positively evaluated in the study from 1997 than in the study from 1994; the reason for this increase can be found in the different use of the promotion program by the grant recipients. As shown in the previous section, *specific* and *non-specific* vocational promotion measures can be distinguished. With the increase of *specific* vocational measures, which enable higher vocational degrees, a promotion in the vocational career could be realized more often. Higher responsibility, higher positions and better payments were the indicators of such a promotion of vocational career in this questionnaire. Although the period since participating in the program for both test groups was quite different, it is surprising that the positive effect was similarly evaluated.

Furthermore, those who chose the *non-specific* vocational measures, evaluated the promotion program

quite positively, even though, it was less important for their vocational career. More essential for the grant recipients was obviously their personal benefit.

Another important variable for the analysis of the promotion conditions was the size of the companies employing grant recipients. Particularly grant recipients of smaller firms could benefit more from their promotion of careers than grant recipients of bigger companies. The cause can be seen in the context that higher vocational degrees (e.g. master craftsman), mostly in the technical area, are demanded by those grant recipients who did not pass high school. These are young employees who mostly come from small craft and trade companies.

The conditions in mostly bigger sized commercial companies are just the opposite. For A-level grant recipients who more often chose commercial vocations and mostly took part in non-specific vocational training courses instead of courses that lead to higher vocational levels, a promotion of career is less often possible in their companies. Another disadvantage for the careers of young employees of bigger sized companies can also be seen in the fact that leading positions are mostly occupied by academic personnel.

Another study of 300 representatively selected top managers, however, showed different results (Manstetten, 1996, p. 63). Here non-specific vocational qualifications, such as problem solving, leadership, teamwork etc. were evaluated as being very important for the promotion of gifted young employees. But this is not a contradiction insofar as specific and non-specific vocational qualifications should be regarded as complementary, but not as alternative; i.e. non-specific vocational qualifications must obviously be regarded as very important, but not sufficiently so for successful attainment of higher positions in a company.

Therefore, it is a positive aspect that the program also supports—apart from specific vocational qualifications—non-specific vocational qualifications. Those were not only chosen quite often, but they were also evaluated positively by the former grant recipients. Particularly valuable were foreign language courses combined with stays in foreign countries, measures for the promotion of communicative abilities and personal abilities. Grant recipients who passed these measures felt more competent and self-confident in various areas of their personal and vocational lives.

All in all more than 20% of the questioned persons have improved considerably since their promotion by the program; nearly 50% have reached a higher position in their companies. Grant recipients from the first test group had attained more attractive positions and responsibilities than their peers; three-fifths work as trainers in their companies whereas this share is normally only 15%; 30% occupy leadership positions compared to 18% of the same age group (Fauser/Schreiber, 1998, p. 6). In this regard a positive career development can be observed shortly after the partici-

pation in the promotion program. Along with the goal that this program should primarily promote attractive careers as an alternative to university studies, the research results showed how far the positive effects could be stated. The question is very interesting because 50% of the grant recipients have the prerequisite to study at a university.

A total of 24% of these grant recipients decided to study at academic institutions like universities; this seems to be rather low compared to a ratio of 40% of the same age-group. The propensity to study at universities of the second test group decreases to 19%. At the same time—as described above—both groups showed that a decision for higher specific vocational degrees had increased. Therefore, it can be summarized that the promotion program contributes to a higher attractiveness of vocational careers because it offers an alternative to academic studies (Fauser/Schreiber, 1998, p. 8).

### Résumé and Concluding Remarks

Vocational education has been regarded as equal to general education in Germany since the beginning of the 20th century. Today, 100 years later, vocational giftedness seems to have a similar fate: Vocational giftedness has long been ignored as a research field in pedagogy as well as in psychology. This deficit was already criticized at the beginning of this century. New impulses for the research field were set by the program *Promotion of the Gifted in Vocational Training* in Germany as late as the beginning of the nineties.

A first research step has been taken by asking how far psychological gifted models can be used to explain and describe giftedness in the non-academic vocational field. The preliminary analysis of these models shows some positive results. This is particularly true for the models of Gagné and Heller et al. Both models can be seen as a basis for giftedness research in non-academic vocations in the field of technics and commerce, crafts and trades, as well as in social vocations. Nevertheless, both models do not sufficiently explain the specific factors of vocational giftedness itself.

The empirical research of the German Government's promotion program discloses personal and social factors of the gifted in vocational training. The grant recipients are not so much characterized by intelligence and creativity, but more so by the above average achievement motivation in work and learning behavior. On the other hand, this study serves as an evaluation of the grant recipients' preferred courses of further vocational training, as well as the consequences for their vocational career. In this respect former grant recipients evaluated the non-specific vocational courses quite positively even a few years after they finished their program. However, specific vocational courses that lead to higher vocational degrees were particularly useful for a vocational career. Specific vocational courses were mostly chosen by non-high school grant

recipients who primarily qualified in technical areas. Grant recipients with high school degrees—although to a lower extent—see better career opportunities in academic study.

The promotion program seems to be especially career oriented for those grant recipients who have special gifts and achievements in the technical area. This is an area, however, which does not occur in curricula of general, non-vocational schools; therefore, it is obvious that the questioned grant recipients regard their vocational training as a new chance and a highlight.

It has to be criticized that the promotion program of the German Government is restricted to promote gifted young people after their graduation from initial vocational training. There are hardly any concrete measures during the initial vocational training. The few examples that exist in vocational schools for the promotion of specially gifted young people are mostly related to the extension of general teaching contents (e.g. additional lessons), or they are based upon higher degrees which were acquired at former general schools (e.g. establishing special classes for A-level trainees in vocational schools). Therefore, they are primarily aimed at the promotion of general education and not at the promotion of vocational qualifications (Manstetten, 1996, p. 24; Kusch, 1995, p. 57).

Promotion by companies during the initial vocational training of young gifted employees is mainly limited to the performance of additional high-level tasks or the participation in vocational achievement contests (Pütz, 1998, p. 32). These measures are—contrary to the school examples named—related to the extension of vocational qualifications, but they lack continuity and systematization which is typical for learning processes in schools.

For all these reasons a systematic vocational promotion of gifted young people is still in its early stages; the deficits which were criticized at the start of this century, still exist. This is not only related to the introduction of concrete vocational promotion measures, but also for the development of adequate procedures and instruments to identify vocational giftedness. The solution of these problems will be an important task for the future and is equally demanded by psychology, as well as by pedagogy.

# Giftedness: The Ultimate Instrument for Good and Evil

Abraham J. Tannenbaum<sup>1</sup>

## Introduction

Probably with a mixture of pride and relief, the renowned psychologist, Edward L. Thorndike, once observed that gifted individuals tend to be friends, rather than enemies, of the people. Applied to outstanding adults, this truism would seem self-evident, because their giftedness is virtually defined by their notable service to society. For after all, they are the ones who design ingenious ways to prevent and heal sickness in body and soul; who enhance the quality of life by creating aesthetic treasures; who make invaluable discoveries ranging from elemental matter to phenomena in the broad universe; who contribute incomparably to the world's knowledge bank; and who demonstrate wide or deep expertise in existing knowledge. Indeed, the extraordinary abilities of these men and women *are* their most prominent virtues, to the extent that the human family benefits from them.

Missing from this euphoric definition of mature giftedness is its ugly reverse side. The selfsame creative and cognitive strengths that serve society with distinction are sometimes turned against it with tragic effect. For example, the so-called 'Angel of Death', Dr. Joseph Mengele, used his medical research talents to conduct some of the most outrageous experiments on innocent people whose living bodies he regarded as disposable slabs of meat, bones, and sinew. In the world of art, Leni Riefenstahl's riveting cinematography is on display in the documentary, 'Triumph of Will', which depicts the revolting pageantry of a pre-war Nazi rally in Nürnberg. The setting is an ornate facade of a building and a huge plaza that faces it, where torches and floodlights pierce a black night, revealing long streamers, emblazoned with swastikas, that seem to hang from the top of the building to the ground of the plaza. A phalanx of uniformed, banner-bearing troops marches into the plaza, row by row in perfect formation. Automaton-like, they tramp to the sound of a martial drumbeat that goes on and on until

all the marchers have taken their places at attention. Adolph Hitler then appears on a tall balcony of the building, his face beaming against the backdrop of night, and he proceeds to harangue his huge audience of uniformed and civilian adorers, whipping them into a state of ecstasy. What a vivid foreshadowing of the bloodbath soon to spread over Europe and much of the rest of the world, captured in a masterpiece of filmmaking! How priceless its propaganda value must have been!

Mengele and Riefenstahl and other highly gifted scoundrels are understandably absent from any list of notable achievers, but they do belong in a rogue's gallery of brilliant villains. Of course, such a galaxy of sinister movers and shakers consists only of adults. In children, however, giftedness is generally viewed in value-neutral terms. Rather than defining and identifying them by what they can contribute to society today or someday, they qualify as gifted only if they think faster or deeper or more creatively than most of their age peers. The school years are often considered too early in a person's life to worry about right and wrong applications of faster, deeper, and more creative thought.

Such complacency is unfortunate because so much is at stake in guiding gifted children to dedicate their special abilities eventually to pro-social, rather than anti-social, causes. Since there is a proven link, imperfect as it may be, between early promise and mature performance and productivity (Oden, 1968), it is essential for the gifted to learn that great character has to serve as the mediator of great accomplishments; otherwise, the brilliant mind can become the most destructive force in the world. The purpose of this chapter is, therefore, to help psychologists and educators: (1) see a clearer picture of moral principles and their relationship to brainpower; (2) appreciate more fully how giftedness carries with it enormous potential for evil as well as good; and (3) explore the possibilities of interweaving 'duties of the heart' with brilliance of the mind.

### Issues in Defining Moral Codes

Morality is recognizable through pro-social values, including empathy, humanism, justice, and the like, along with appropriate derivative traits. It seems unnecessary to define morality, a term that is well known to be associated with "what one ought to be, to do, or to have," in contrast to "what one is, was, or may become." The operative referent, as Havighurst & Taba (1949) point out, is *character*, with its subsumed attributes that are judged on a scale of right or wrong, in contrast to *personality*, which includes only those descriptors that delineate a person's individuality in non-evaluative terms. Thus, character calls attention to love, ethics, charitableness, and trustworthiness, among other qualities one is obliged to have. Personality, on the other hand, is reflected in people's tastes (e.g. music, art, literature, etc.) and interests (e.g. sports, recreation, travel, etc.), or in anything that is viewed with a live-and-let-live attitude, even by those who do not necessarily share another's tastes and interests. Character also incorporates immorality, when it involves publicly resented traits, such as misanthropy, misogyny, bigotry, and brutality.

For a formal psychosocial definition of morality, perhaps none is more serviceable than Martin L. Hoffman's (1979): "[M]orality is the part of personality that pinpoints the individual's very link to society, and moral development epitomizes the existential problem of how humans come to manage the inevitable conflict between personal needs and social obligations" (p. 958).

### Subjectivity in Defining Morality

Beneath the surface rendering of the concept, there are complications, the first of which is its parameters. Does it require not only moral *judgment* and a feeling of moral *responsibility*, but also *acting* in accordance with this judgment and responsibility? Secondly, there is the matter of conflicting applications. In the name of morality, people have argued pro and con regarding abortion rights, genetic engineering, mercy killing, legalizing drugs, and recognizing homosexual marriages. This suggests that while there may be general consensus on the *need* for moral codes to guide human belief and action, there can also be considerable discord on how, where, and when to employ the codes. A third issue relates to the question of "whose ox is being gored." One side in an armed conflict condemns the enemy guerrillas as terrorists, whereas the other side idolizes these partisans as freedom fighters. Are both attitudes valid, morally, depending on who espouses either of them? Fourth, there are questions of internal consistency and generality among those who subscribe to particular moral principles. Is a person who is honest in family life necessarily honest in reporting financial data for income tax purposes? If a President of the United States is proven guilty of marital infidelity while in office, does it necessarily

cast doubt on his (or her) sincerity in promoting family values as public policy?

Behavioral scientists are especially concerned about a fifth issue pertaining to the psychological structure of morality. Is it analogous to a cognitive 'g' factor, defined by the religiously oriented as belief and involvement in the *sanctity* of life, or by secularists as the active *celebration* of life? Or, as Gruber (1993) argues, there are various forms of morality, including "Justice Morality (Kohlberg, Piaget); Caring Morality (Gilligan); Truth Morality (Asch); Freedom Morality (Fromm, 1941); The Work Ethic (Veblen, 1914); Planetary Morality (Ehrlich & Ehrlich, 1991); Religious Morality" (pp. 8, 9). All of these are subsumed under a general life morality which Gruber defines as "the superordinate combination of caring and planetary morality" (1993, p. 9). Shades of theories of intelligence proposed by Spearman (1927) and Vernon (1960) which make room for overarching general abilities and related specific aptitudes.

Finally, there are various orientations concerning the origins of moral codes in humans. From a theological point of view, a Jewish scholar (Hutner, undated) quotes the Biblical passage in *Genesis* (II, 7) "... and He breathed into [Adam's] nostrils the soul of life, and Adam became a living being," and comments that the 'soul' of life carried with it a nobility of character which Adam shared with Eve and which both bequeathed to all subsequent generations. Specifically, the all-virtuous Creator transmitted part of Himself, as it were, to the human race by breathing virtue, along with life, into Adam.

From a completely different orientation, the zoologist (and editor of *The Economist*), Matt Ridley (1996) offers an evolutionary explanation of morality's origins by tracing cooperative behaviors in humans to similar traits in other living creatures, including ants, fish, naked mole rats, and baboons. Ridley believes that people tend to work together constructively when they are prepared to trust and trade with each other.

Still another perspective is suggested by the classical scholar, Moses Hadas (1967) who locates the roots of modern society's humanism in ancient cultures that populated the Tigris-Euphrates valley. It was then reinforced by the multitudes who were inspired by the Old Testament's vision of people caring and taking responsibility for each other. But nowhere did it flower more richly than in the ancient Greece of Homer, Socrates, Plato, Aristotle, and in the accompanying classical art and literature. This confluence of Hellenistic genius spread its influence to other parts of the world, and it still inspires humanistic leadership in modern society. However, Greek sophists took humanism to a dangerous extreme by encouraging individuals to place themselves at the center of the universe, with little concern for the needs and plights of others. Such a belief is perhaps best expressed by Shakespeare's foolish schemer, Polonius, in his oft-quoted advice to

Laertes: "This above all—to thine own self be true. . .," not to some higher principle of morality.

What creates social harmony, then, in a world of Ayn Rand-type radical egotists is the social contract, as in Thomas Hobbes' *Leviathan* (1996), which recognizes no intrinsic principles of right and wrong. Instead, human beings adopt a mutual survival pact, not unlike the United States–Soviet Union mutual deterrence of mass destruction, based on the fear that each possessed the means to annihilate the other in relatively short order. And there was enough hatred between them to render their 'peace' into a more realistic 'cold war'.

People usually subscribe to principles of morality and can even agree on what these values are; but they interpret and invoke them in different ways that often lead to dispute or even conflict. The sheer complexity of morality as a construct may help explain why it is difficult to penetrate below the surface of platitudes that overlay the phenomenon so often in everyday conversation. Educators are also stymied by the puzzle and may assume that it is futile to teach morality in school until the fog of mixed meanings is lifted. Besides, many teachers are convinced that such instruction rightly belongs in the home and places of worship.

Perhaps most discouraging to scientists and educators is that, to them, morality seems approachable either pragmatically or dogmatically, neither of which is appealing to the rational mind. From a pragmatic point of view, there are no eternal values, only those which fit transitory needs. Schwartz (1990) suggests that values are contextually determined and supports his contention with evidence on how they can be created or destroyed in laboratory experiments. They therefore do not lend themselves to scientific generalization about their origins, how they change over time, and how they influence behavior. Instead, according to Schwartz, they are subject to the specifics of times, places, social norms, and the institutions that exert leadership. Consequently, "[A]ttempts to extract what is timeless and universal about the formation of human values from the particulars that are important at any given time or place are likely to lead to distortion. This distortion can be especially serious if historical contingencies are mistakenly identified as natural laws" (p. 15).

No wonder that scientists who see the systematization of moral principles and their origins as an impossibility often ignore the subject in their studies; they are more committed to generalizing than to particularizing; and without some rules about the nature of morality, educators may lack, or think they lack, the guidelines for nurturing it. If a sizable number of scientists and educators consider dogmatism as the only alternative to Schwartz's brand of pragmatism, they could find themselves in the precarious position of promoting eternal verities in a laboratory or a schoolroom where proselytizing is unacceptable, even in a

non-sectarian format. For similar reasons, warning against evil is not a popular practice in psychological counseling or classroom instruction.

### Some Ideational Visions of Morality

Clearly, 'ought's' and 'ought not's' are elusive by nature, even among those who take a strict-construction view of morality. Loving-kindness is an unquestionably noble trait under ordinary circumstances, but hazardous foolishness when practiced by innocent victims toward their assailants bent on hurting them. Equally, self-defense is occasionally an acceptable excuse for pre-emptive strikes against an imminent attack. But even though there are times and places for violating good or practicing evil, ideationally, good and evil are timeless—yes, even dogmatic—constructs. Benevolence is virtuous and aggression is vile despite the fact that they can be misapplied and often are.

Behavioral and social scientists and educators seem reluctant to posit ideational descriptors of morality as they do for cognitive, creative, motivational, and social portrayals of people. Perhaps they consider the nature and nurture of the utopian good life self-evident, and words are not adequate to describe it without sounding preachy. Thus, instead of approaching the phenomenon as a universal concept, contemporary theory and research concentrate mainly on how morality develops, how its development can be measured, how it can be clarified subjectively by those in search of personal values to live by, and what its mental and emotional correlates are, with only casual attention to the true nature of the profound 'it' in all its glory. Hesitation among students of human nature to commit themselves to a vision of morality, even in a chimerical state bordering on fantasy, probably helps inhibit teachers and counselors from daring to promote virtue and to discourage harmful inclinations in children's belief systems. For the gifted, this reluctance can have devastating consequences since superior brain power, harnessed to unprincipled motives, poses threats to the human family that are far out of proportion to the incidence of such couplings in society. In simple terms, a brilliant villain or a brilliant dupe serving villainous causes, though mercifully rare in public life, is the most dangerous of living species, just as the high-minded, highly able handful is the world's most precious possession.

### The Need to Concretize the Visions

For many centuries, the Ten Commandments, the Seven Deadly Sins, and The Confucian Analects have individually or collectively addressed the conscience of

huge segments of the world's population. The purpose of this widespread dissemination has been simply to guide people to embrace righteousness and to reject wrongdoing. Yet, there are people who express respect for these keys to morality but are guilty of causing death, hunger, and bondage among countless humans. Is it just a tiny minority, consisting of those who give only lip service to morality, guilty of spreading havoc, whereas the vast majority abide by the ancients' tenets about the good life? Or is it possible that traces of cruelty lie dormant in most people and can be brought to life by authority figures, as in Milgram's (1974) experiment with normally law-abiding citizens who followed orders to administer what they thought were near-lethal electric shocks to strangers? If so, the popular, age-old precepts and scriptures serve merely as a thin veil to cover people's baser instincts that can be aroused to turn masses into willing executioners of innocents (Goldhagen, 1996).

It is conceivable that the printed word and the vocal plea for universal morality, such as peace on earth and goodwill toward mankind are only ideational visions with limited persuasive power. Possibly, even the language of Beethoven's music, combined with Schiller's 'Ode to Joy' are only powerful enough to arouse deep aesthetic sensitivity, but not to advance the cause of the brotherhood and sisterhood of all humanity. The only alternative, then, is to concretize these lofty ideals into behaviors of individuals who qualify as role models. Instead of drawing the big picture of morality, the concept may best be approachable through its constituent details as exemplified by single specific behaviors or habits of the famous, not so famous, and even unknowns. What follows, then, is a sample of some defining morality attributes and the names of real individuals who have been known to possess them, and at least a few of whose lives deserve to become familiar to young students.

Morality is the *passion for freedom* that characterized Dietrich Bonhöffer, Osip Mandelstam, and Arturo Toscanini, whose self sacrifice in their battles against tyranny is legendary. Bonhöffer died at the hands of the Nazi regime; Mandelstam was tortured and finally put to death in a Soviet Gulag; and Toscanini lived in self-imposed exile from the Fascist domination of his beloved Italy.

Morality is the *dedication to world peace* displayed by Mildred Norman, the 'Peace Pilgrim', who hiked well over 25,000 miles to campaign for peace on earth. An earlier heroic figure of her kind was the great French writer Romain Rolland who passionately rallied the intelligentsia of Europe to use their prestige and influence to avert World War I, albeit without success.

Morality is the *dedication to racial equality*, as personified by the likes of W. E. B. DuBois, Martin Luther King, Jr., and Arthur Schomburg, who contributed so much to overcome resistance to black integration in American society. Even today, long after

their death, their influence remains alive and powerful against bigotry, separatism, and ignorance.

Morality is belief in the *sanctity or celebration of human life*, as perfected by Eleanor Roosevelt through self-discovery, self-acceptance, and self-deliverance from emotional pain and from feelings of inadequacy, to become the conscience of the fledgling United Nations and the beloved caretaker of the downtrodden throughout the world. In their study of her values and behaviors, Piechowski & Tysk (1982) conclude that she was a truly self-actualized 'Doer' in the sense that Maslow (1970) defines the term.

Morality is the *leap from expressing sympathy to feeling empathy* for fellow humans, especially the broken spirits, that Mother Teresa demonstrated in the squalor of Calcutta, India. Her values contrasted sharply from those who loudly profess a love for humanity and for identifiable segments thereof, but fail tragically in one-to-one relationships, be it in marriage, family life, the workplace, or in informal social groups.

Morality is *modesty and honesty* that characterized the psychometrist and researcher, Robert L. Thorndike, who spent about five of the last years of his highly productive life preparing a revision of the Stanford-Binet Test. Soon after its completion, he remarked to this author, "Abe, my job is finished, but I'm not sure that the new instrument is an improvement over the previous one." How many productive behavioral scientists would be willing to confess doubts about their success after completing an exhausting labor of love?

Morality is *personal integrity*, as practiced by behavioral scientists, Irving Lorge and Miriam L. Goldberg, who would not agree to be listed as co-authors of their respective students' or colleagues' publishable research without actively participating in the conduct of the studies and in the reports of outcomes. Lorge and Goldberg resisted the temptation to lengthen their lists of publications, and thus enhance their professional reputations, even when they played vital roles in advising on the study designs, the accurate presentation of results, and honesty in interpretation.

Morality is just plain *human decency and thoughtfulness*, as exhibited by this author's four-year-old grandson who would accept a cookie from his mother only if she also gave one to his playmate. This habit was practiced without ulterior motives to curry favor from his mother or out of fear of punishment if he were to act selfishly. Sharing and caring behavior as a matter of principle among mere four-year-olds is an oddity that does not seem compatible with age- and stage-related theories of moral development.

Obviously, morality embraces a much greater array of human attributes than the ones listed above. Furthermore, to those familiar with the personalities of the real people who are named as exemplifying these aspects of morality, it is equally self-evident that the

descriptive behaviors are not context bound or restricted to the single traits attributed to these individuals. The campaigners for peace felt that way about warlike situations in general; so did the individual exponents of empathy, honesty, and decency generalize their defining characteristics in large varieties of situations involving these principles. But while they were consistent in demonstrating the values that made them notable, the question is to what extent their moral superiority crossed over to other domains of pro-social behavior. For example, did those described as possessing uncommon personal integrity also distinguish themselves in fostering social equality? Again, the question reduces itself to the issue of whether morality manifests itself in discrete ways, or whether there is at least a partial common denominator among them. If there were a kind of 'g' factor combining aspects of all forms of morality, it would probably be defined, as Gruber (1993) suggests, an extraordinary regard for the human race, its sub-populations, and its individual members.

The most promising advantage of illustrating specific moral traits through the behaviors of real people is that the concept thus becomes more teacher friendly. It is easier to teach earthbound, kindly habits than to deal with morality as a vague, Utopian abstraction and trying to make it a governing influence on students' lifestyles. Easier, but not easy. If the instructors are virtuous role models and able to show how heroic figures and unknowns, even four-year-olds, behave laudably, there is a chance that students will try to adopt at least some of these habits and absorb at least some of the underlying convictions. In the last analysis, pedagogic methods have to be tested and confirmed as effective and applied to instill morality in children at school. For to neglect the humane development of young personalities,—either out of fear of failure or out of conviction that such matters belong outside of school—is clearly risky; riskier when it involves the gifted. The reason is that there is no way of knowing precisely where the talents of unprincipled able students will be directed—towards good or towards evil—when early promise is fulfilled in the adult years.

### **Conflict and Consensus on How to Examine Morality**

#### *Occasional Conflict*

There seems to be a fair amount of contrast in scholarly approaches to morality and immorality. Hutner's (undated) theory of God instilling virtue in human beings is countered by belief in original sin (Hoffman, 1970) which emphasizes the need for proper upbringing and other supportive experiences to counteract people's immoral inclinations. Behavior management specialists move nurturance into the realm of specifics by itemizing virtues to be reinforced and by elaborating

on proper reinforcement tactics. No rationale for reward or punishment is necessarily communicated to the person whose behavior is being modified.

A much different dynamic is suggested by Freud (1955) who, unlike reward and punishment change agents, was most interested in the antecedents and causes of moral behavior and proposed elaborate methods of helping clients to engage in intensive introspection for better self-understanding. Freud believed in deep analysis to expunge guilt feelings which can surface if moral principles do not suppress antisocial impulses from operating at the conscious level.

Guilt has no place, however, in Maslow's (1954) humanitarian orientation, with its focus on self-perfection through self-fulfillment, which can be accomplished by human beings nurturing their potential for dignity, autonomy, personal integration, and by satisfying their needs for social attachment and altruism. According to Schneider (1998), Maslow's protagonism for personal worth and perfectibility continues to influence the work of social scientists who study personology, industrial organizational psychology, and educational psychology. Schneider concludes: "Thanks to the influence of Maslow and other existential-humanistic psychologists (e.g. Rogers), there have been significant increases in the trends toward worker participation in management, meaning-based jobs, and human relations training. . . . There has also been an increased recognition of the roles played by empathy, emotions, and creativity within the educational setting. . . . Arguably, these factors are integral to the . . . social responsibility movement in our culture and to a resurgent quest for meaning. . . ." (p. 282). These views are in sharp contrast to Elliot's (1997) observation that psychologists today often perceive Maslow's ideas as quaint, romantic anachronisms in the worlds of social and behavioral sciences. Friedman (1992) goes so far as to hold Maslow partly responsible for the 'me-generation's' narcissism in the 1970s.

In essence, then, the aggregate of theories of morality are basically in a point-counterpoint, thrust-and-parry relationship with each other rather than in a complementary, mutually reinforcing arrangement. To make matters even more complicated, the theories have to deal with change in American value priorities. For example, Rokeach & Ball-Rokeach (1989) report an encouraging increase, from 1968 to 1971, and then a disturbing decrease, from 1971 to 1974 to 1981, in America's valuation of *egalitarianism*. The authors note that these findings contrast with outcomes of another survey which shows impressive increases in positive attitudes toward *integration* between 1942 and 1983. Also noted are the generally lower levels of support for *equality* as reflected in attitudes toward implementing racial integration through legislation, government aid, and the like. Rokeach and Ball-Rokeach suspect that the differences in findings

resulted from variations in questionnaire formats in these surveys.

There is reason to believe that values do change over time, regardless of how they are tapped by surveyors. Note, for example, the more recent study by Wolfe (1998) which shows that Americans have more respect for *diversity* than they have had in the past, clearly another sign that values are changeable. This kind of instability may help explain why some researchers prefer to study how people mature in their understanding of why they embrace particular moral beliefs rather than just studying the nature of these beliefs *per se*. It may also be a reason for the delayed popularity of Piaget's book, *The Moral Judgment of the Child* (1932) which was fairly neglected for decades until psychologists began to view morality from a developmental cognitive perspective. Piaget's monitoring of moral maturation in children has served as a strong basis for Kohlberg's contributions to the field.

#### *Occasional Consensus*

No other body of thought about morality has attracted as much testing and commentary (pro and con) as Lawrence Kohlberg's theory of moral development (Puka, 1994a, 1994b, 1994c, 1994d, 1994e, 1994f, 1994g). It is redundant to repeat much of what has already been written, except to add comments and comparisons that are not often made. One probable reason for its popularity is that it has the distinction of dealing with morality and yet does not promote a package of virtues. Moral relativists and pragmatists can relate to it easily. Even dogmatists can identify with insights into their own maturation in embracing what they consider eternal values.

Kohlberg (1963, 1964, 1966) acknowledges Piaget's influence on his thinking, but he also argues for the need to discredit the earlier work of Hartshorne & May (1928–1930) who defined a package of virtues consisting of *honesty* (i.e. avoidance of cheating, lying, and stealing); *service* (i.e. sacrificing personal possessions for others' welfare); and *self control* (i.e. task persistence). The basic method for assessing these virtues was to note the frequency of occurrence in situations where children's behavior was not disciplined or monitored by authority figures. The outcomes of these investigations convinced the researchers that honesty depends on the situation, not on an internalized, consistent set of values.

Kohlberg (1964) disputes this conclusion, offering alternative ways of interpreting the results. More important, he expresses disappointment in the Hartshorne and May belief that moral principles are determined in early childhood by the home environment and that character education and religious education had no real impact on children's honesty and service, as measured by the Hartshorne and May tests (Kohlberg, 1966). These outcomes seem to help account for Kohlberg's avoidance of positing a virtue

package and for moving him closer to Piaget's (1932) developmental theory. They may also account for the lukewarm commitment (at best) of schools toward mounting serious character and citizenship education programs.

In his book on the unity of knowledge, Wilson (1998) uses the term 'concilience' to describe the sense of accordance of two or more lines of induction drawn from different sets of phenomena. Kohlberg's model which is primarily developmental and cognitive, along with Dabrowski's (1964) paradigm on positive disintegration, which is also developmental, but non-intellective, combine with each other and with Perry's (1970) framework of epistemological development to form a concilient relationship that sheds combined light on moral maturity, albeit from different conceptual sources. Their parallelisms and convergences can best be illustrated by placing them side-by-side, as shown in Table 1.

A simple inspection of the three models reveals a fairly invariant stage progression from rigidity, self-absorption, and dependence on authority to more sophistication, flexibility, and independence as the person matures. The number of stages is roughly the same, and there is either a conceptual or empirical relationship between the models at various stages. Yet, there are differences in interpretation of what *causes* movement from one stage to the next. As a cognitive psychologist, Kohlberg (1966) saw role taking and guided personal reflection as powerful facilitators of moral development. This was demonstrated in Turiel's (1966) study of three sixth grade groups, matched for IQ, which were engaged in role-play and discussion sessions that centered on hypothetical conflict situations similar to the ones that appear on Kohlberg's tests of moral development. Each group used moral judgments at one of three levels, either at its own, or one above its own, or one below its own. Only in the case where the children engaged in one above their levels did they show meaningful absorption of the older group leader's own moral judgments. Another experiment involving classroom discussion produced similarly encouraging results (Blatt & Kohlberg, 1975). Kohlberg et al. (1972) also used the role taking and discussion methods to help prison cottage populations to become justice-oriented communities, with moderate success.

The process of moving to higher developmental stages was seen by the psychiatrist, Dabrowski (1964) as an active effort by the organism to transform itself from within rather than rely passively on maturation and on cognitive stimulation from without. He calls the mechanism for change 'positive disintegration', marked by a deep inner struggle to reject one's present, familiar value motives in order to reach a higher level of belief and understanding. In other words, less mature psychological structures are broken down by profound, disturbing restlessness and distress and

Table 1. *Three Developmental Theories and Their Parallelisms..*

Stage	Kohlberg (1969) (Cognitive development in moral reasoning)	Dabrowski (1964) (Stages in positive disintegration)	Perry (1970) (Epistemological development)
1	Avoidance of punishment and the superior power of authorities.		Relevant experiences are judged as absolutely right or wrong, true or false, good or bad, and authorities are believed to have the right answers to all questions.
2	To serve one's own needs or interests in a world where you have to recognize that other people have their interests too.	Primary integration, marked by egocentrism. Lack of sympathy or self-examination, personal ambition without a sense of personal responsibility.	
3	The need to be a good person in your own eyes and in those of others. Belief in the golden rule. Desire to maintain rules and authority which support stereotypical good behavior.	Uni-level disintegration: moral relativism, conformity to mainstream values, and indecisiveness in choosing between competing values.	Alternative judgments are possible and equally valid, but there is no standard of preference of one over the other.
4	To preserve the social system and one's own conscience. Worry that the system may break down if individuals deviate from it. The violator's conscience may thus be threatened, too.	Spontaneous multi-level disintegration, in which the person develops an hierarchical sense of values. A dissatisfaction with what one is because of awareness of what one ought to be. The struggle between the 'is' and the 'ought to be' can produce anxiety, self-doubt, and a restless need for personal change.	Recognition of relativism only in academic tasks and exercised only when allowed by authorities.
5	A sense of obligation to law because of one's social contract to make and abide by laws for the welfare of all and for the protection of all people's rights. The greatest good for the greatest number.	Organize multi-level disintegration; the individual is finding a way to reach his or her personal ideals and thereby achieve a new sense of autonomy of thought and action, self-awareness, and acceptance of others. This degree of maturation resembles and is comparable to Maslow's advanced progress toward self-actualization.	Relativism begins to permeate all thought. Knowledge itself requires relativistic reasoning in the sense that an interpretation is right only in terms of a particular context or frame of reference. This means that a variety of perspectives have to be considered.
6	The belief, as a rational person, in the validity of universal moral principles and a sense of personal commitment to them.	Secondary integration of values and ideals on the one hand and everyday living on the other. The person's social space makes room for compassion toward others and a sense that every aspect of experience is guided by principles, not by personal motives or social dictates.	The possibility of commitment within the relativistic universe is recognized. That commitment evolves over time, as contexts change.

replaced by greater moral responsibility, empathy, sensitivity, and autonomy. As in the Kohlberg and Perry models, few people ever reach the highest stage. Those who do are the rare creative souls who seem

capable of experiencing a commitment to what Gowan (1979) calls 'agape love', or an all-embracing, total identification with humanity. 'Agape love' is the peaceful culmination of a turbulent development from

narcissism, on to oedipal attachments to parents, and love partnerships in the years when such feelings can be aroused. These particularized expressions of love form the basis for an all-embracing 'agape love', which are closely associated with profound creative impulses.

Powering the inner transformations from one stage to the next are five overexcitabilities that can be expressed in any of the following forms: psychomotor, sensual, intellectual, imaginal, and emotional. According to Piechowski (1979), these overexcitabilities combine with "original endowment [to determine] what level of development a person may reach under optimal conditions" (p. 28). In a study of graduate students, Lysy & Piechowski (1983) found that the emotional and intellectual excitabilities were most closely associated with higher development, as defined by Dabrowski. Within an adolescent population, Piechowski & Colangelo (1984) detected two different types of exceptionally bright children, (1) the *rational altruistic*, who possess short-term goals and engage in little introspection; and (2) the *introspective-emotional*, who demonstrate more concern about understanding life's existential meanings. Small wonder that the Dabrowski model, with its emphasis on self-regeneration and its hyper-motivational drives, is of such growing interest to scholars concerned about understanding and stimulating gifted behavior (Maxwell & Silverman, 1995; Nelson, 1995; Morrissey, 1996; Piechowski, 1997).

Besides showing some resemblances to the Kohlberg and Dabrowski models in the form of change from early stages of rigidity and conformity, to the higher levels of freedom and flexibility, Perry's theory of epistemological development seems to add a dynamic dimension to understanding Kohlberg's model. In a study by Clinchy, Lief & Young (1977), a high correlation (0.7) was discovered between Perry's and Kohlberg's systems among high school senior girls. This is important, in light of speculation by Gruber (1993) and Runco (1993) that morals may be immutable principles and therefore orthogonal in their relationship to the spontaneity and venturesome of creativity. One would expect Perry's developmental stages leading toward relativistic moral thinking to describe the unfolding of creative impulses that veer away from what seems to be the uncompromising, conservative nature of moral beliefs. Yet, the Clinchy, Lief & Young results reveal the opposite—that the relationship is strong, despite other empirical evidence to the contrary (Andreani & Pagnin, 1993a). The latter study uses a categorical analysis and measures creativity through a divergent thinking test, the type of instrument that has been criticized as questionable in validity (Baer, 1993, 1993/1994). Besides, if morality and creativity relied on opposite cognitive styles, shouldn't the correlation hover around  $-1$  rather than 0?

Perry's model and its subsequent evaluation suggests that it may be simplistic to consider moral values as hard-and-fast rules applied predictably in every moral dilemma. Kohlberg's stage 6 and Dabrowski's stage 5-type people are not superficial ideologues at peace with their values. Instead, they are cognitively flexible enough to weigh alternatives before judging how, where, and when to apply them, by Kohlberg's standards, and emotionally mature enough to sense the nuances of right and wrong, case-by-case, according to Dabrowski's standards. Inasmuch as the Clinchy, Lief & Young study is only a single investigation of a female high school sample, it should be replicated on more representative populations. If the first results are confirmed, moral development would take on new clarity. Further, the more recent investigation of culture and conformity (Bond & Smith, 1996), which discovered a decline in conforming behavior over the past four decades, especially in 'individualist', as opposed to 'collectivist', countries, may also signal a general rise in epistemological development and, by extension, moral maturity.

### **Giftedness and Morality: Are They Compatible?**

As a social construct, giftedness can be defined at will, unlike objective phenomena, such as height and weight. Even when children are viewed strictly in their early and school-age years without concern about their ability to sustain excellence in adulthood, arbitrary standards are used, such as an IQ level or signs of asynchronous development (Silverman, 1997), in which intellect and creativity are observed as outracing social, emotional, and physical development, at some unspecified speed. The same kind of subjectivity accounts for the tendency to cast specific talents in a morally upright mold. For example, it is assumed that Gardner's (1983) intelligences are meant as pro-social potentialities, with no thought that they can and might be used for evil purposes. Similar positive applications of gifts and talents are implied in Gagne's (1991) model of differentiated forms of excellence.

### *Some Basic Issues About the Relationship*

Talents are sometimes turned into destructive forces, even if the association is too rarely noted in the scientific literature. Moreover, when individuals are guilty of anti-social behavior, they are usually placed near the low end of moral maturity, which is to be expected. For example, Kohlberg (1958) describes the delinquents he was attempting to reform as considerably less mature in moral judgment than those in the comparison sample. Nelson (1995) likewise places one notorious General Secord, who promoted bloody wars in Iran and in Nicaragua out of lust for money, at the lowest primary integration level in Dabrowski's hierarchy. Ignored is the likes of an Adolph Hitler, a genius (or more appropriately an evil genius) who used his talent for demagoguery, and whose charisma and

great skills in manipulating masses captivated his countrymen more effectively than any other political leader in his nation's history. He surely climbed to the top of the heap as a political power through rare interpersonal ingenuity, combined with intimidation. Without ever forgetting his immoral *behavior*, one has to admit that he climbed the ladder of immoral *maturity* in a way that parallels the *process* by which exemplary figures move from one *moral* stage to the next. For him, disintegration of earlier beliefs was surely negative in effect, but it helped him escape his personal demons that held him captive in his early years. Later, through some kind of epiphany, which he recorded in his book, *Mein Kampf* (My Struggle) while in jail, he reached a state of idealism, twisted to be sure, that enabled him to gather the inner strength of a visionary fanatic and to rally a powerful following that would encourage him to actualize a dream of fashioning a master race to rule the world.

The point is that gifted villains can reach Kohlberg's and Dabrowski's highest developmental stages and use their combination of brains and hate-filled over-excitabilities to threaten the quality, and even the existence, of life on our planet. Schwebel (1993) describes how creative artists and writers can be forces for the common good through the exemplary works they produce. Conversely, in an equally searching analysis, McClaren (1993) brings to light the destructive potential of arts, sciences, and technology. Whether intellectual and creative gifts will be used for positive or negative purposes depends upon the values of those who possess them. No wonder that Piechowski (1997) pleads for more attention to the moral needs of able children.

#### *A Classification of Talents from a Moral Perspective*

In addition to focusing on childhood precocity, one may also consider the connection between early promise and its later fulfillment. Does the child show early signs of social leadership, or scientific reasoning, or legal acumen, or a flair for literary or musical expression, or any other developed talent that is appreciated in the broad cultural world? Of course, the public celebrates superior brain power that is directed to a common good, which makes it morally defensible. Viewed from this perspective, talents can be categorized as follows:

- (1) *Scarcity talents*, that are rare and universally appreciated because they heal, preserve, and prolong life. The world is always in need of people inventive enough to make it easier, safer, healthier, more intelligible, and more obstacle-free. Although it takes only a single Jonas Salk to achieve the breakthrough in conquering polio, there can never be enough talent like his for the great leaps forward that still need to be made in medical science. The same can be said for extraordinary leadership in politics, race relations, mental health, and in all matters that are critical to well being. Society will always venerate such talents as they appear, while thirsting for more and more because the shortage has never been filled.
- (2) *Surplus talents*, that are also rare and universally appreciated, not for their making survival possible, but because they make life meaningful. Included are the arts, music, literature, theater, and philosophy, among others, that elevate people's sensibilities and sensitivities. Without them, life would reduce itself to a hollow existence. They are labelled 'surplus' to suggest that our cultural treasures are super-abundant and life is too short for an individual's possible exposure to all that exists and all that is being added constantly. But nothing in that treasure should be considered superfluous so long as its contents can have deep meaning for people who savor them.
- (3) *Quota talents*, which include specialized high-level skills needed to provide goods and services for which the market is limited. The jobs to be done are fairly clear; there are no creative breakthroughs expected and no way of knowing precisely how long the opportunities for such work will last. Job openings for the relatively few who qualify depend on supply and demand, which can be irregular and limited geographically. Schools are probably most responsive to the public's needs for quota talents, and advanced training programs designed to fill top level positions in various occupations constitute the major effort at differentiating education for the gifted.
- (4) *Anomalous talents* are different from the ones already mentioned, not in their nature but in their applications. Some include feats that are intellectually and creatively sophisticated but are not often judged to be signs of excellence. Examples include speed reading, mastery of mountains of trivia, gourmet cooking, trapeze artistry, performance of complex mathematical calculations faster than a computer, and even the numbers of sexual seductions boasted by Don Juan.

Those who possess anomalous talents also include people who possess scarcity, surplus, and quota talents but use them for anti-social purposes. It takes sophisticated talent to develop biological and chemical weaponry. If the results of such efforts are placed by the researchers in the hands of an unscrupulous political power, the results could be the annihilation of life rather than its preservation. Likewise, cultural activity and high level quota productivity can serve a tyrannical state either by helping build it or simply as 'window dressing'. It is obvious, then, that giftedness has its moral and immoral applications, and it would be

a serious mistake for its nurturers to regard it as invariably pro-social or even value-free.

#### *What Is (and Isn't) Clear about the Relationship*

Whether or not giftedness and moral behavior belong together depends on how the relationship is examined. One source of evidence is historical, which takes the long, impressionistic view, and the other is empirical, which relies on the examination of relatively small sample populations, closely and methodically. Nobody can doubt that great men and women have played important roles in making history, for better or worse, but mostly better. The liberal arts and sciences have always served society brilliantly and continue to do so, even if a few of their most gifted exponents work against the common good or have chosen these professions primarily to gain prestige or material security. This may be 'only' a historical perception, but it is hard to escape the feeling that those who possess scarcity, surplus, and quota talents deserve to be proud of their tradition of virtuous leadership in human affairs. The mean-spirited among them have never succeeded in destroying that tradition, even if they have weakened it from time to time.

As for the empirical evidence, there are problems in interpreting it, due to restrictive methods of gathering data on both independent and dependent variables. In most studies, giftedness is defined exclusively as a high score on an IQ test. Ignored are personality and social indicators as well as special aptitudes that are not measured by IQ. Besides the oversimplicity of equating precocity with high IQ, there may be implicit bias in relating IQ scores with performance on pencil-and-paper tests or interviews on moral reasoning, which are used so popularly today, since they are all measures of cognition. Instruments for assessing the latter essentially reveal how maturely people rationalize the values they espouse, regardless of what these values are. The instruments do not pretend to clarify whether a person is a do-gooder or even a believer in doing good; to further complicate matters, the relationship between moral reasoning and moral behavior is not established. Thus, even though it is likely that having a high IQ gives its possessors an advantage in moral reasoning, it does not necessarily guarantee their putting those morals into practice.

Methodologically, there are two approaches to studying giftedness and morality. One is *categorical*, in which high-functioning subjects are compared with those of lesser ability; the other is *correlational*, involving samples that range widely in ability. Of the two kinds of studies, the categorical yields more consistently encouraging results. Probably the earliest categorical study on the subject was conducted by Terman (1925) on more than 600 elementary school children with an average age between 9 and 10 and with IQs above 140. Taking into account the fact that the instruments used for measuring moral status were

not as valid as the ones assessing moral reasoning today, the children apparently showed a healthy set of virtues, including unwillingness to claim undeserved credit for work accomplished, choosing socially constructive activities relatively often, rather than those that were just personally gratifying. When the Terman high-IQ sample reached its senior year in high school and freshman year in college, these students again responded to a pencil-and-paper test of trustworthiness. Results showed that their scores were comparable to those of other well-educated late adolescents (Burks et al., 1930).

The outcomes of Terman's longitudinal study seem to have been reinforced by Hollingworth's (1942) finding that children with IQs of 180 and above are particularly tortured by universal problems of good and evil, justice and injustice, honesty and dishonesty, and other such ethical issues. Hollingworth (1942) concludes, "The higher the IQ, the earlier does the pressing need for an explanation of the universe occur, [and] the sooner the demand for a concept of the origin and destiny of the self appears" (p. 281).

In later years, Boehm (1962) studied the moral reasoning of 237 children between the ages of 6 and 9, among them a subgroup identified as 'gifted' (with IQs of 110 and higher). The children were tested on Piaget's three levels of morality: (1) automatic obedience to rules without reasoning or judgment; (2) internalization of rules without evaluating them; and (3) evaluation of intentions rather than deeds or outcomes alone. Results show that above-average IQ children matured earlier in their moral judgments concerning distinctions between intention and outcome of an action than children of average intelligence. Moreover, the difference was greater among the upper middle class children than among those coming from the working class.

Less encouraging outcomes were revealed in research by Hoffman (1977) involving children ages 7-8 and 11-12 divided into subgroups of average IQ (91-109) and superior IQ (124-156). The criterion measure was also a test based on Piaget's stages of moral development. Results show that age was a more important predictor than IQ, as the older children with close to average IQs scored higher than did younger children with superior tested intelligence. Karnes & Brown (1981) likewise produced strong support for a relationship between age, along with high IQ, and advanced moral reasoning. Their sample consisted of 233 children, ages 9-15 with a mean IQ of 126.5. The data reveal the expected steady increase in appropriate Level 3 responses from ages 11 to 15. There is also a positive correlation between intellectual functioning and the ability to make more mature moral judgments. The evidence suggests that high-IQ children may reach Level 3 moral reasoning in their high school years, even though most people never reach this level at any

age. In fact, the estimated 10–15% of the general population that succeeds in reaching it usually does so in adulthood.

In a study using Kohlberg's Moral Judgment Interview, Form A, Bear (1983) compared 14 intellectually gifted 6th graders with 46 of their non-gifted peers. In this case, giftedness was defined as a score above the 95th percentile on the Vocabulary scale of the Stanford Achievement Test. Bear found that the high achievers scored approximately one-third of a stage higher than their lower achieving peers on the Kohlberg instrument.

More than half a century after Hollingworth's report, Gross (1993) also assessed a small sample of children with extremely high IQs and of late elementary and early junior high school age. This Australian group took Rest's (1986) Defining Issues Test (DIT) which is influenced by Kohlberg's theory of mental development although, as Rest, Thoma & Edwards (1997) acknowledge, "DIT researchers have taken some turns [in the design of the instrument] that Kohlberg would not have endorsed himself" (p. 6). Of the eight children whose IQ scores ranged from 160–175+, five had z-scores of at least +1.00, compared to the norms obtained from a somewhat older American junior high school population, and two of the children exceeded the senior high school average by a z-score of more than 1.00. The other four children also exceeded the junior high school norm, which further indicates a positive relationship between high tested intelligence and moral reasoning.

In contrast to the categorical studies, correlational research provides little confirmation of links between giftedness and morality or moral reasoning. In her review of the evidence, Gross cites several studies that "have found significant correlations between scores on individual group tests of the intelligence and scores on measures of moral development" (p. 253). On the other hand, Janos & Robinson (1985) appear less impressed with the outcomes of several studies cited by Gross, despite the encouraging results of their own investigation. From their review of empirical evidence, they conclude as follows: "In early research on the character of gifted children and in more recent work on moral judgment within a social-cognitive framework, significant relations with IQ have been found. These studies have not, however, yielded satisfactory predictors of moral behavior" (p. 152). Hoffman (1970) also reviewed several investigations and concluded that "The relation between IQ and the moral attributes formulated by Piaget are consistently positive" (p. 271). A close inspection of the various correlational studies confirms a fairly high consistency in positive results but it does not dispel the conclusion that IQ explains only a small portion of the variance.

Other correlational studies confirm the fact that IQ figures in moral reasoning, as it does with other forms of logical analysis, without serving as a powerful

factor. A study by Durkin (1959) sampled children from grades 2, 5, and 8 whose scores ranged widely on a group intelligence test. The objective was to investigate the children's concept of justice, as described by Piaget, and its relationship to age and IQ; results confirmed Piaget's contention of a relationship between chronological age and feelings of equity. However, no such clear result was obtained in relating IQ to an understanding of justice. In another study involving a moral judgment measure based on Piaget's work, Johnson (1962) tested 807 subjects in grades 5, 7, 9, and 11, all approximating the United States norms in parental occupation and IQ. In this case, IQ and chronological age were significantly related to scores on most of the subtests.

In sum, how can one characterize the relationship between giftedness and moral development? The only sizable body of literature on the subject confines itself to high-IQ subjects to represent the entire spectrum of gifted children, an approach that is obviously inadequate. What the categorical studies reveal about children with high IQs is that their ability gives them at least some moderate advantage in moral reasoning. This is to be expected if moral development is boosted by the kinds of cognitive skills that are measured by IQ tests. But, as Winner (1996) points out, "While the fascination with ethical issues may come with the territory of a high IQ, the *content* of one's moral code seems far more likely to be determined by the values of one's family" (p. 221). Her reasoning is in line with Kohlberg's (1969) speculation that the moderate predictive strength of IQ may be represented in the connection between more rapid cognitive and social development. The enriched social interaction opportunities within families of high-IQ children and adolescents may account for some advancement in their moral reasoning.

In Rothman's (1992) assessment of research on the subject, "Age accounts for most of the variance in moral reasoning . . . with variables such as IQ and socioeconomic status playing more moderate roles" (p. 329). However, the correlation between moral maturity and IQ increases as individuals grow older, perhaps on account of an accumulation of educational experiences which are enhanced in high-IQ individuals (Colby et al., 1983).

All in all, there appears to be some compatibility between giftedness and moral maturity, judging from impressions of the history of great ideas and from evidence on high-IQ populations who seem to be advanced in moral reasoning.

#### *Conclusions about the Compatibility*

Reflecting on both the systematic-empirical and the impressionistic-historical perspectives on giftedness and morality leads to several moral dilemmas and reflections; some have already been noted, but are worth repeating because they persist. One nagging

question is whether moral development, which is currently measured by interviews and pencil-and-paper tests of a cognitive variety concerning moral dilemmas, favor test takers who may not necessarily act morally out of lofty conviction but who possess the brainpower to be labeled gifted and to see the wisdom of subscribing *intellectually* to more principled moral codes.

Conversely, is the instrument 'biased' against those who lack the reasoning skills to *express* the higher moral principles that are reflected in their actual *behavior*? Also, what if more serious attention were paid to partialling out, or controlling for, such variables as socioeconomic status, risk-taking behavior, home environment, school achievement, and whatever else correlates with measures of giftedness? Would it change the relationship between giftedness and moral development appreciably? Are other superior intelligences or special aptitudes, which correlate poorly with IQ, also associated with moral advancement? Why is the correlation between IQ and moral reasoning only 0.13 in one study (Andreani & Pagnin, 1993a) and range from only 0.20 to 0.50 in another (Rest, 1984)? Does IQ really explain so little of the variance, even without partialling out related factors? Finally, and perhaps most important, how does one account for the rather poor connection between moral reasoning and moral behavior, even at the highest levels, as described by Rothman (1992), and between moral reasoning and moral responsibility, as discussed by Gruber (1985)?

Perhaps one way of escaping some of these difficulties is to stop thinking about relationships between giftedness and morality and to consider, instead, the possibility that morality is a *form* of giftedness. Colby & Damon (1992) have already studied adults whose only claim to prominence was their legendary kindness. But that does not diminish the ethical imperative of researching other forms of giftedness and its relation to moral behavior.

### Extra Cautions in Interpreting Relevant Evidence

Empirical studies usually come in two varieties: (1) mass data analysis and (2) single-subject clinical diagnosis. Both require strict objectivity in the exploratory phase of the research. After the *facts* are gathered and analyzed, there is a changeover to the search for *truth* through interpreting the facts and drawing inferences from the interpretation. In the quest for truth, there is always the danger of personal bias or just plain misjudgment. For example, producers and consumers of research sometimes stretch their comprehension of study outcomes beyond reasonable meaning, as in the case of overgeneralizing central tendencies in mass data analysis and in fitting clinical diagnosis outcomes into private predilections. These

are especially sensitive matters when they pertain to moral values and practices of the gifted.

### *The Invited Tyranny of Central Tendency*

In the analysis of mass data, scientists look for statistical central tendencies from which to draw generalizations. Reporters and readers of research acknowledge exceptions to a generality and yet often accept it so dogmatically that the exceptions hardly seem to count. The consequences can be harmful, as in the case of the bold, but not perfect, correlation between IQ and scholastic achievement. In much of the literature on the gifted who are not excelling in their studies, it is assumed that if a child scores high on an IQ test, he or she should perform at a comparably high level in school work. Whoever fails to measure up to expectation is dubbed an 'underachiever', a failure, when in reality whoever labels the child that way may be guilty of neglecting to prove that the failure is *not* due to the *imperfect* relationship between IQ and achievement, which can be explained by test error and which would occasionally account for the discrepancy. The unfortunate consequence is stigmatizing some children with an unfair label and force-feeding them with unnecessary 'intervention' which can cause embarrassment to them and to the interveners, all of whom are laboring under unrealistic expectations.

Overlooking exceptions to a rule that is relevant to 'underachievement' can be a serious matter. But trivializing exceptions to the rule of strong ties between giftedness and morality can result in far more monstrous threats to society. In his long essay, *When Learned Men Murder*, Patterson (1996) reminds readers that the notorious Wannsee conference, organized on January 20, 1942 by the Nazi leadership to facilitate the 'final Solution', took only two hours to work out the ways and means of murdering all Jewish people in lands under current and future Nazi control and influence. Of the small group of fourteen conferees, eight held Ph.Ds from prestigious universities, and included among them, ironically, was the Minister of Justice. One can only speculate as to how many highly educated individuals played important roles in 'ethnic cleansing' more recently in the Balkans. Of course, there is room for quibbling over whether earning a Ph.D is a sign of giftedness, an argument that this author can appreciate since he, too, owns that degree. But at the very least, people who have successfully completed advanced schooling must have been exposed to great ideas, as taught by instructors with impeccable credentials in scholarship and who must, or should, have taught something about the greatness of the human mind and soul. What could have been lacking in the Wannsee Ph.Ds' education?

Sometimes, gifted people who are probably not mean-spirited can become the instruments of others' evil intentions, either out of naiveté, indifference, or greed. For example, it wasn't outlaw science that has

posed what may become a permanent insult to the planet's biosphere. In his collection of essays on mortality and morality, the philosopher Hans Jonas (1996) attacks members of the scientific community for failing to reconcile nature and humanity, following or leading to the belief that both the universe and life on earth have no intrinsic meaning. No wonder that the work of relatively few superior rational minds has facilitated fouling the environment without malice aforethought, but also without concern that organic life may face extinction as a consequence. Fortunately and ironically, though, Jonas sees hope albeit only in the kinds of rare gifted intellects that created the problem of human survival in the first place. Lesser brainpower would not be sophisticated enough to discover remedies for our environmental ills. Thus, some creative individuals in some branches of science deserve to be condemned for bringing about the impending tragedy. Yet, science has to be advanced along with proper nurture of the consciences of its budding practitioners so that they can dedicate their research to undoing what a few of their predecessors have wrought.

In sum, a *sine qua non* of studying an aggregate of gifted children and providing adequate education for them is to take seriously the minority among them who may not turn out to be pillars of society. These are not just negligible, non-conforming minorities; their superior abilities may someday be used for harmful purposes, so harmful in fact that they can threaten the good accomplishments of the overwhelming majority of their gifted peers. It is not just another case of a rotten apple spoiling the healthy ones in a barrel; this kind of rotten apple has the contagion power to contaminate a whole orchard.

#### *Clinical Understanding vs. Moral Judgment*

There is also a lesson to be learned by scientists who study individuals in clinical detail. Hoffman (1992) reports that during World War II, behavioral scientists working for the American government produced a number of innovative studies on the nature of Nazism, Adolph Hitler's personality, the German national character, and Germans' reactions to the war. One of the committees in this effort consisted of a group of psychologists working on "Hitler's Mentality and Personality," directed by none other than Lewis M. Terman whose famous *Genetic Studies of Genius* is still the largest scale, most ambitious longitudinal investigation of high-IQ children.

The original purpose of the project was to undermine Nazism by waging psychological warfare against Hitler and other German leaders. Although some of these studies amounted to breakthroughs in clinical research, the methodology and purposes have evolved into occasional blurring of the boundaries between deep understanding and justifying anti-social behavior. For example, the revered psychoanalyst Erich Fromm seems to have allowed his clinical insights to over-

power strict accountability for the crime of genocide, as reported in his 1973 book, *The Anatomy of Human Destructiveness*. His subject was Adolph Hitler whom Fromm regarded as a victim of necrophilia, a love of death and dead bodies. Unlike popular notions that Hitler suffered abuse from a cruel and aggressive father, Fromm's thesis focuses on the mother, Klara, as guilty of a 'malignant incestuousness' with her son. According to Fromm, Germany became the central symbol for mother, and his hatred for the Jews whom he saw as threatening Germany, actually concealed a deeper, long-repressed desire to destroy his mother. Thus, Hitler's deepest hatred wasn't Jews—it was Germans. This kind of analysis can be used to justify Hitler's spearheading genocide as the product of an understandably deranged, and therefore blameless, mind.

A similar sentiment was expressed by a Harvard Medical School Psychologist (Westen, 1998) who suspects Ted Kaczinski (the convicted Unabomber) of being a victim of paranoid schizophrenia and therefore possibly treatable. Westen asks, "Is Kaczinski any more morally responsible for his acts than a person who becomes impulsive or dangerous after a damaging blow to the head?" (p. 16). It causes one to wonder whether the clinical and behavioral sciences are reaching a point where enemies of the people, brilliant or not, can be understood and treated without penalty, thus reducing the legal system to punishing only violators of the law who are somehow confidently declared sane or socially adjusted at the moment of committing a crime.

#### *Teaching Moral Values to the Gifted (and to the Non-Gifted, too!)*

Experimental programs in moral, or character, education are not often evaluated. Those that report somewhat encouraging results feature mostly discussions of moral dilemmas and how to solve them more maturely (Rest & Thoma, 1986). In such cases, the criterion measures assess moral reasoning, not moral values or behaviors; in the rare instances where programs sought to build pro-social habits, the impact has been minimal (Andreani & Pagnin, 1993b). Why? Is it because schools are basically weak in affecting students' habits of honesty, decency, and compassion? Or are they not trying hard enough or with much pedagogic ingenuity?

If laxity is the cause of failure, it is well for educators of the gifted to memorize, or at least reflect on, the sentiments of a now-deceased popular psychologist who was a World War II Holocaust survivor.

My eyes saw what no person should witness. Gas chambers built by learned engineers. Children poisoned by educated physicians. Infants killed by trained nurses. Women and babies shot and killed by high school and college graduates. So I'm suspicious

of education. My request is: help your students to be human. Your efforts must never produce learned monsters, skilled psychopaths, or educated Eichmanns. Reading and writing and spelling and history and arithmetic are important only if they serve to make our students human. (Ginott, 1972, p. 317)

In Tannenbaum's book, *Gifted Children: Psychological and Educational Perspectives* (1983), he suggests a curriculum framework for enriching the education of the gifted. One of its elements refers to the social and affective consequences of becoming a high-level producer or performer. In introducing this feature, Tannenbaum warns: "Perhaps the worst possible outcome of an enriched program is that it will produce a cadre of technocrats who are brilliant in the work they do but have no conscience or commitment to a set of values, and are willing to sell their talents to the highest bidder" (p. 438). It is no surprise that the warning has gone unheeded.

Character education has not had a notable history in America's schools, possibly because Hartshorne and May have shown how futile it is to instill moral values in the classroom, or perhaps because the American public is just plain worried about exposing children to hot issues that they see as belonging only in family and religious environments. A *New York Times* (July 8, 1995) report on efforts to introduce such a program in the Mount Lebanon, PA school system describes how sensitive the topics of study have been. For example, 'Respect for Life' was discarded because of suspicions that it might have led to disputes over abortion and euthanasia. 'Respect for the Environment' was also never introduced because ecology activists and industrialists could disagree on its meaning; and, of course, the topic of 'Race' was avoided because of the extreme emotions it would arouse. It is no surprise that the warning has gone unheeded by psychologists and educators who seem to attend only to cognition and creativity in children with high potential.

The Lebanon effort is fairly unique among schools across the United States, and this lack of widespread commitment is also evident in educational efforts on behalf of the gifted. For example, the National Research Center on the Gifted and Talented has produced a publication entitled *Setting an Agenda: Research Priorities for the Gifted and Talented Through the Year 2000* (Renzulli, Reid & Gubbins, undated), which reports a needs assessment study involving 13,749 respondents to a questionnaire that canvassed their priorities in the field. In the Personal and Social Development section of the questionnaire, items included social adjustment, emotional adjustment, guidance and counseling, peer relations, family relations, and underachievement. No mention is made of moral education which is so critical to the gifted.

What follows, then, are some suggested exercises in moral education that may arouse or restore interest in

alerting the gifted to the centrality of moral principles in their lives. It is by no means comprehensive, but its fragmentary nature suggests further development possibilities wherever desirable or feasible.

#### A. "Know Thyself"—the Issue of Self-Knowledge

"Who am I?" (the development of a time-unlimited portfolio into which entries are made whenever something important can be added in the following four categories)

(1) *Pride in Specific Accomplishment*. Describe or enclose anything you have achieved that gives you unusual satisfaction. It may be academic documents that you have produced, acts of kindness, creative works, etc.

(2) *Personal Identify*. Describe how you would distinguish yourself in a crowd. It could be through your deeply absorbed values, beliefs, and aspirations; perceived personal strengths, weaknesses, physical features, etc.

(3) *Choice of Heroes, If Any*. If you have a hero, or more than one hero, such persons may be of any age group and not necessarily well known to anybody else. Write something about these heroes that supports your choice.

(4) *Deepest Commitments*. Indicate what values or beliefs you are willing to embrace, even if it means suffering discomfort to embrace them. Are there any that are so precious to you that you are willing to make real sacrifices for their sake? If so, record your feelings.

This "Who Am I" portfolio contains each student's private documents, and the privacy has to be respected by staff and administration. However, staff should meet with students periodically, perhaps bimonthly or once every semester, to discuss whatever the student wishes to share with the staff member. Needless to say, the importance of building such a portfolio may have to be communicated periodically to the student body. Under no circumstances should students feel that this is a formal 'assignment'; instead, it is a format for helping them to serve their own needs to clarify their own personae.

#### B. Learning that Life can be a Challenge

*Conflict Resolution*. Staff members familiar with the work of Morton Deutsch and Herbert Kellman, who have written extensively about conflict resolution, may then use the derivative methodology for dealing with strained personal relations. The Internet can retrieve the strategies tested and successful in reaching this goal, or at least approaching it more closely.

*Surviving and Benefiting from Frustration*. Since gifted students experience frustration in school work relatively rarely, it should be pointed out to them that

creative writers sometimes suffer writers' block, scientists' experiments don't always unfold as planned, musicians don't always hit the right notes in concerts, and artists sometimes 'climb the walls' while trying to express an aesthetic message. But these creative minds persevere and even push themselves to greater heights, rather than become discouraged and give up.

*Experiencing and Overcoming Temporary Failures.* Artists, writers, and scientists are not only occasionally frustrated in the process of creating, but sometimes their work turns out to be unsatisfactory to them. Instead of having a demoralizing effect, the failure encourages them to continue or to renew their efforts. Alexander Fleming's early failure in his search for penicillin and Thomas Edison's repeated failures to produce the light bulb, followed by success in both cases, are excellent examples of overcoming temporary failures, and worth studying.

*Delay of Gratification.* Many students demonstrate their precocity by giving quick, accurate answers to teachers' questions and solving problems at high speed. Some of these students may have learned that impatience is a virtue and either refuse, or are unable to wait for results to come in due course. Biologists always experience delay of gratification because plants and insects and animals have to grow to the point where success or failure of an experiment can be determined. This habit of patience should be emphasized in the course of teaching in all disciplines.

*Risk Taking.* Some students prefer guaranteeing success for themselves by concentrating on what they know they can accomplish, thus sustaining their positive self-image. But it is important for them to be encouraged to enter into unknown realms which increase the possibilities of frustration or even failure, so that they can reach higher levels of achievement.

Teachers may use various methodologies for emphasizing the principle of professional life's challenges. One way is to introduce students to the productive experiences of artists, writers, and scientists, with special attention to their resolution of conflicts, frustrations, temporary failures, delays of gratification, and occasional willingness to take necessary risks. Teachers may even use their own experiences to illustrate these principles.

### C. Alienation and Changes in Identity

*Dehumanization.* Reading Franz Kafka's *The Trial* will illustrate to students the meaning of having no name and about being victimized by legal accusations and processes that are not understood by the accused. In Kafka's *Metamorphosis*, the central character is not viewed as a human being, but rather as an insect. Students can also learn that racism and genocide have

strong elements of dehumanization directed at the victims. There is a subtle but profound difference between lower status in social life and being regarded as a non-person and thus disqualified from membership in the human community.

*Misogyny and Liberation.* Henrik Ibsen's *A Doll's House* illustrates marital relations gone sour because of the diminutive role of the wife; it would be interesting for the gifted to speculate on what happens to Nora after the end of the play. August Strindberg's *Miss Julie* can also help students see how women's identity has been so marginalized in literature and society. It is important for the gifted to see how females' status has become far more honorific at the end of the twentieth century than at its beginning. Finally, a study can be done on Betty Friedan's vision of women's status in *Feminine Mystique* and the changes that have occurred in her later book, *Beyond Gender: Individualism vs. the Voice of the People*. Sometimes, personal identity can be so strong that it is forced to battle against consensus. All agree that the majority should rule, but the majority can be wrong while the individual who thinks differently is right. A good example of that is Ibsen's *Enemy of the People*, which should be read and discussed.

In the sciences and arts, too, there are notable examples of individuals who contested conventional thinking and the *status quo* and were even unpopular on account of their courage. But eventually, their individualism proved to be productive and creative. Teachers in the sciences and arts should make students aware of the professional histories of prominent people in their fields who have become immortalized, despite their swimming upstream.

### D. Language, Knowledge, Creativity, and Values

As underscored in other parts of this chapter, scholars and creative thinkers are mostly moral benefactors as well as moral role models in society. But it is necessary for schools to work toward the ideal of enabling all gifted young people to become that way, because the few who do not may someday use their superior brainpower to cause incredible harm in the life of humanity.

*An Introduction to General Semantics.* S. I. Hayakawa has written the book, *Language in Thought and Action*. This work includes instructions and exercises to help the reader distinguish between fact and opinion and how words are used to manipulate the reader's or the listener's emotional reactions. It is a valuable guide for students, who are already advanced in language comprehension, to learn how to read newspaper reports that use words for the sake of persuasion rather than enlightenment. Hayakawa's approach to general semantics can also be useful in reading or listening to political pronouncements, analyzing advertisements,

and generally strengthening the relationship between communicating knowledge in any field and the degree of subjectivity and value coloration it contains.

*Medical Ethics.* Issues surrounding euthanasia and assisted suicide have swept through the medical profession in recent years. But they are not the only ethical issues that people in the health services face every day. In every region of the country, there are people in the health professions who are becoming more and more aware of the importance of Bio-ethics, and children who may someday enter these sciences should become aware of this developing field and of the growing concerns it addresses.

*Scientific Truth and Empirical Fact.* The case of Dr. David Baltimore, a Nobel Prize winner and former president of Rockefeller University in New York City, reads like Greek drama and the rise and fall of an assortment of tragic heroes. One of several major issues raised in that episode in American science relates to the risk that researchers take in seeking out truths in their empirical data that may deviate from the hard facts. Another issue deals with the freedom of scientists to experiment and to explore in their fields without governmental controls that are intended to avert possible harmful effects of research. A full report on the Baltimore case by Daniel J. Kevles (1998) deserves to be read and debated in great detail among students in the sciences, especially in biology.

*Genetic Engineering and Its Possible Consequences.* Although this is a widely addressed topic in newspapers and journals, gifted students should review the experimentation with sperm and eggs from high-IQ people in order to produce an intellectually able population. Also, the 'creation' of Dolly in Great Britain has stirred a good deal of commentary. Students ought to discuss the possible connection between the eugenics of creating a generation of high-IQ individuals and the cloning of animals, on the one hand, and the production of a master race on the other.

#### E. A Rogues' Gallery of Great Minds.

It is important for students to have concrete examples of people who have achieved greatness while living evil lives. Even though they constitute only a minority of geniuses, the power of their depravity, combined with their creativity, had a negative and often lethal effect on countless individuals. Gifted students should be introduced to at least some of these historic figures and remember them in infamy for the rest of their lives:

- (1) Wilhelm Furtwaengler is the major subject of a powerful play titled *Taking Sides*, which deals with a conflict between the great orchestral conductor's devotion to recreating immortal

music while serving Hitler as an unwitting or guilty emissary of Nazism.

- (2) Ezra Pound and T. S. Eliot, two of the leading literary figures of the twentieth century, were both anti-Semites, although Pound was also a major spokesman for Mussolini's Fascism.
- (3) Joseph Stalin, Adolph Hitler and Mao Zedong, highly gifted leaders who could manipulate millions of subjects through their political intrigue, demagoguery, and social skills, and yet guilty of wholesale murder at home and abroad. Though tiny in number, but notorious in tyranny, these despots deserve far more than their proportionate share of blame for the massacre of some 170 million civilians and the war-related deaths of roughly 30 million soldiers in all of the twentieth century (Conquest, 2000), a total approximate the entire population of the United States today.
- (4) Leni Riefenstahl, actress and highly gifted filmmaker, whose Nazi-era masterpieces include the films *Triumph of Will* and the *1936 Olympics in Berlin*, both used as propaganda instruments at a crucial time in Nazi history.
- (5) Joseph Mengele, whose brutal experimentation with human beings may have produced meaningful results. Should these outcomes be added to our storehouse of scientific knowledge? The same can be asked about psychological studies by Nazi behavioral scientists, and the circulation of the '*Pernkopf Anatomy*', a classic anatomy atlas, produced by the Nazi doctor Eduard Pernkopf, onetime dean of the medical faculty at the University of Vienna.
- (6) Werner Heisenberg, the Nazi scientist who nearly completed the development of an atomic bomb for Hitler's Germany ahead of the American scientists. Heisenberg's position in this rogues' gallery is particularly strange and interesting. In 1967, the New Americana Library initiated a series of studies under the general heading 'Perspectives in Humanism', with a Board of Editors consisting of distinguished scholars, among them Werner Heisenberg. This is the same man who had visited the United States to participate in a high-level conference on science in the 1930s, and was urged by other participants at the meetings to remain in the West and enjoy its freedom, but he refused. Cassidy (1996) suggests two possible reasons for Heisenberg's loyalty to his homeland and its outlaw government. One is that he craved personal advantage, prestige, and high status in his field, which he felt only Germany could provide for him. The second is that he was never aware of the need to share with fellow Nobel prize winners the responsibility of battle against injustice and oppression. In a strange way, this may help explain his identification with humanism, for as the eminent social

psychologist, Brewster Smith (1991), points out, humanism serves as an umbrella for individualism and sometimes even for narcissism.

- (7) Werner Von Braun, one of Nazi Germany's leading rocket scientists who helped rain rocket-propelled bombs on London late in the war and who was brought to the United States after the war to contest the Soviet Union's domination of deep space exploration. Did the United States solve this moral dilemma?
- (8) 'The Monster' is a brief biographical study of a famous composer by the music critic, Deems Taylor. Should his music be appreciated even though he was a monstrous megalomaniac, liar, and cheat?
- (9) Albert Speer, whose autobiography should be 'must' reading for the gifted, because of its revelation of the author's genius combined with unspeakable evil.
- (10) Pablo Picasso, one of the twentieth century's greatest artists, whose mistreatment of women was unforgivable, despite his ability to depict women with so much insight in his artistic works.

### A Final Thought

This chapter is but a brief outline of some prominent ideas that have been propagated by theorists and researchers on the concept of morality. The summary was intended to lead in the direction of a sincere plea to persist with dedication and imagination in making moral education an integral part of enrichment for the gifted in the hope that it will enhance their learning experiences and encourage them to serve society with guidance from its highest ideals. The plea for unrelenting efforts is best captured in the final paragraph of Patterson's (1996) essay:

The event of loving embrace that distinguishes teaching is a consecration of life through a testimony and pursuit of the sacred, for the sake of all that is sacred. However, simply asserting this is not enough. It is needful but not sufficient. From here we must return once more to begin again and ever again. Though the task has been met a million times, it remains forever yet to be done; for the debt increases in the measure that it is paid. And so, having said this, let us return to our students for the encounter that lends life meaning (p. 162).

# New Trends in Research on Moral Development in the Gifted

Adriano Pagnin<sup>1</sup> and Ornella Andreani<sup>2</sup>

## Introduction

Morality is generally conceivable as a set of basic guidelines for determining how decisions about action and solution of conflict between different interests/ points of view are to be settled and a consequent behavior is to be accomplished.

As morality has to do with judgements about rightness of behavior, it is based on strictly cognitive aspects on the one hand (analysis of behaviors and their consequences, discussion of normative assumptions), and on motivational and affective aspects (motives for following assumptions in practice, and capacity to do so) on the other.

So, we believe that we need two sets of reflections on the development of morality:

- moral behavior is based on specific cognitive ability and specific education towards rational analysis and discussion of actions concerning rights, duties, consequences (about life, affects, well being, etc.) of self and others;
- moral behavior is based on affective roots and emotional education (in terms of empathy, commitment to others, care for others).

Much research has been devoted to the study of development of moral judgement in general, starting from the classical studies of Piaget (1932) and Kohlberg (1969); but a few were devoted to connection of moral judgement with moral behavior, and to interventions aiming to enhance them, and very few to analyzing those specific aspects in the gifted.

But we can also study characteristics of the gifted by considering the highest intelligence subjects in studies aiming to other objectives, where data for those subjects are reported. So we will emphasize the interest of research results for the gifted and for gifted education.

We shall consider moral judgement as related to intelligence, special abilities or academic success: not

only moral judgement in the gifted, as only few researches have been made specifically on the gifted in this topic, as the Psychinfo database can show, except for some retrospective biographical study.

In the meanwhile, social development of the gifted was studied aiming mostly to analyze their adjustment to others, popularity, leadership, or problems in interacting with friends. Only a few studies were devoted to altruistic or pro-social behaviors and to moral development.

## Definition of the problem

We have assumed as gifted subjects those subjects with a high IQ (5–10% superior of the population), rather than those with an extraordinary IQ (2% superior or less), so we have considered a relatively wide range of people. This way we examine high intelligence subjects from a point of view that intersects basic qualities (those also determined in relationship with their genetic background) with the opportunities for action and the cultural and environmental chances that enable them to 'cultivate' the genetic endowments in due course. Therefore our attention is laid more on the cultivation processes, being more interesting and more promising in the research fields, rather than on the selected ones.

Moreover, we consider giftedness as a high general ability rather than a specific skill: we do not examine here peculiar skills or abilities – music, painting, mathematics . . . but only the development of generally gifted subjects, seen from the viewpoint of moral thinking and moral behavior. This way we feel it important to draw our attention to the moral development of the gifted, rather than starting from the theory of an existing specific giftedness in the moral, a theory that we see as rather doubtful. So, our attention is driven to the moral development of the generally gifted subjects, rather than to the strict selection of the morally gifted ones.

Then, we shall consider the relationship between some concepts, frequently used in similar contexts: they need a few specifications and they may elicit a few

problems, too. We are talking about the concepts of moral judgement, moral behavior, and morality.

In the concept of moral judgement, the importance of the evaluation process is stressed, rather than the decision-making one (it is to judge if an action is right or wrong, and not to decide if making it or not), and the focus is settled on the cognitive and developmental aspects, on which a large part of the psychological research has concentrated its efforts and to these aspects we will also pay a great deal of attention.

The concept of moral behavior is, on the other hand, particularly complex, because it covers different themes and problems, and only some of these can be treated and studied by psychology:

- social behavior aspects, among which are different social abilities. We have to remember that not all abilities concerning social success are involved, but a major part is played here by the empathic role-play, rather than self-presentation and manipulation skills, and the back up ability is considered more important than persuasion and influence capacities;
- structural individual features, as the so-called 'psychological maturity', defined differently by the authors; we could recall here the 'classical' definition by Freud, as the "ability to love and work";
- personality features in the social field, such as identifications and basic social relationships;
- altruism and prosocial behavior, expressed in several forms, depending on which society or culture we are investigating; nevertheless, we can presume the presence of a general common (super-cultural) basis, which seems to send us back to biological grounding;
- in the concept of moral behavior there is a reference to subjects (which actions are moral?) that eventually send us to philosophy or religion; to avoid the intervention of philosophy, some psychologists have tried to study this aspect on the subjective side. This way they have tried to analyze what people think when they morally value or label a fact or an action: what do people mean by morality and moral judgement in their common language?

Basically, most difficulties are due to the superimposition of three different approaches: two psychological and an extra-psychological one:

(1) Moral judgement can be seen as a problem connected to society (and to the human species as a social species). It consists of leading to patterns of behavior which fit social survival (of manhood), seen both as physical survival and as the chance to nourish the quality of cultural relationships and achievements which found the specific heritage of the species;

(2) Otherwise, moral judgement can be seen as an expression of the individual qualities of a person. Those qualities enhance his whole performance, when not measured just as thinking abilities in the traditional meaning, or even as social abilities totally rule-

oriented, but they also include environmental adaptability in the sense of the best balance and wellness possible. So they include empathy, comfort ability and the skill of finding patterns of actions meant to minimize pain and to satisfy the most important needs to oneself and to one's fellow creatures, both on the psychological and the cultural side;

(3) Moreover, the extra-psychological approach identifies the word 'morality' as a concept including a range of behaviors and rules defined by a particular philosophy or religion, or common basis to many of them, considered as lore which shall be pedagogically transmitted. We do not share the same ground, but this approach has to be taken into account when thinking about the problem, because its presence is widespread in the shared representations and expectations. This way those representations can be the objects of our studies: what do people mean when they talk about morality? Which contents do they put into this concept? Which conditions subdue to a morally considered act or problem and what is the difference between morality and legality, opportunity or social ability? Are these conditions the same in different social classes, cultures or societies? This is a typical ground for psychosocial studies.

Aware of the complexity of the problem, we will try to show some guidelines and to give a few remarks on what we consider the most interesting aspects that researches providing useful data have investigated.

### Moral development

The wide range of researches on moral judgement analyze either the relationship between cognitive development or academic success and the stages of moral judgement, or the essential conditions suitable to developing the skills of moral judgement.

On that approach, several books have been recently published, addressed both to a specific or a generic audience (that of educators or parents). And the titles are really catchy ones, as "100 ways to enhance values and morality in schools and youth," "365 ways to develop your child's values" or the more recent, "The moral intelligence of children: how to raise a moral child" (Coles, 1997).

Many books about related topics, as values or character education, have been issued in recent years.

The varied meanings of the idea of moral judgement used in the researches cover angles and perspectives different from time to time: moral rationality and decision-making, the development of the sense of fairness and justice, and of pro-social dispositions, moral self and moral identity.

Although these concepts are strictly linked together, we must underline that there is a clear distinction between:

- the problem of the nature of values, concerning the planning of the action and representing the ideal

domain of social psychology, as well as anthropology and sociology and that of the nature and the development of character, inherent to personality psychology, and

- the domain of moral judgement, more specific and connected to its own tradition in the research, formerly in the philosophical field and more recently also within the sphere of psychology.

Some questions of emerging importance are posed:

- (1) the researches on cognitive and social-cognitive components of moral reasoning: many studies, both psychometric (even conducted with fine statistical techniques, as LISREL) and experimental, have considered the different component of understanding problems and decision making in moral matters, both in cognitive psychology perspective and in the perspective of social psychology.
- (2) the relationship between strictly logical, computational abilities (traditionally emphasized by cognitive stage theories, as well as traditional philosophical approaches) and social-affective components of thinking in moral judgement, which characterize human reasoning: is moral giftedness only a matter of a good computational machine?
- (3) the discourse analysis on moral judgement and the social representation of moral judgement. The place of moral judgement in everyday thinking and the role of social conventions and pragmatic aims in conversations have been the object of a certain number of works: is moral giftedness only a matter of dialectical ability in sustaining one own rights or interests, making them coherent and acceptable to others?
- (4) the researches on moral reasoning in special professional fields (education, economy, and medicine . . .): is moral reasoning part of the so-called 'social intelligence' and of good professional performance?
- (5) the problem of moral giftedness as a special ability: is there moral giftedness at all?

Psychologists have studied this problem for some decades and the traditional perspective distinction is divided into cognitive, behaviorist and psycho-dynamic approaches. Nowadays, the most recent approach is based on new patterns, taking new alternatives into account:

- the choice between the perspective of the subject (decision-making process) and the perspective of the observer (what an observer sees as the object of the moral judgement from the outside);
- the choice between global approaches (where the problem is to value if a judgement is fully developed or not) and component approaches (mainly cognitive: the role of information, of the de-codification, of the euristics);

- the alternative between individual level (which studies individual performance) and processes of interactive construction (how judgement is formed through language and speech);
- the alternative between the pre-eminence of the self (and so of the processes of identification of the defense mechanisms) and the supremacy of the social self (so the pre-eminence of the social expectations and representations which determine it).

### The classical cognitive-developmental approach

Cognitive developmental studies about moral development have stated the existence of a succession of stages in judgement about the nature of rules (both in play and in interpersonal behavior), rightness of actions, distributive and retributive justice.

Piaget (1932) named such stages as egocentric, realistic-heteronomous and autonomous, where reciprocity, consideration of intentions of agents and reference to the functional aims of rules are the discriminatory issues for autonomous moral behaviour.

Kohlberg (1969) searched for a more detailed succession of stages and attributed a central role to the concept of social convention and social rule, differentiating the six stages he found in three groups:

- two pre-conventional, where the rule is a way to avoid punishment or harm and to satisfy one's needs (in the second stage, even reciprocally);
- two conventional stages, where the rule is a way to feel good and to meet the expectations of the social group (stage 3), or expresses the priority of a general social point of view (stage 4);
- and two post-conventional stages, where the rule expresses a more abstract point of view, referring to meta-rules to solve conflicts between specific different norms (stage 5), or to abstract general, absolute principles (stage 6).

In this approach, the sequence of stages is structured in the same developmental sequence as intelligence operations: each new stage employs more differentiated, reversible and equilibrated operations and has a higher degree of generality and abstraction.

The cognitive-developmental approach to moral judgement has sustained the existence of a series of stages in the judgement. They are related to the nature of social rules, the agreement or the liability to punishment of deeds, the modality of the retributive justice (concerning nature and measure of reward and punishment) and the distributive one. Piaget identified three main stages in this development (egocentric, realistic-heteronomous and autonomous), stressing the importance of the very origin of the idea of social rule as a peculiar moment in the general cognitive development of the child.

Kohlberg gave a wider meaning to the existence of stages in the moral judgement and he ordered the levels on the basis of the concept of social convention-rule (two pre-conventional, two conventional and two post-conventional stages). His effort compelled the researchers to overcome the context of social cognition, that is the construction analysis, the understanding and the mastering of social reality, to stretch out towards the idea of a cognitive genesis in the moral individual orientations and behaviors.

We shall remember here that Kohlberg and his students had devoted themselves to the study of moral judgement for more than two decades, using the 'dilemma' method, in which short problematic episodes are shown to the subjects. These episodes are based on several principles, usually known as morally relevant ones, which appear as opposite and incompatible in that specific situation. So the subject is asked to elaborate answers or to choose between different courses of action, and to justify his/her choice answering a series of questions and remarks.

Kohlberg thought morality concerned the managing of the general idea of justice, and he aimed to study the performance of his subjects in the thinking process, which centers on the social justification of action (right or wrong). From this point of view it should be intended as an intellectual performance, though not measurable through a traditional problem-solving process. As a matter of fact, it is not concerned either in the manipulation of univocal premises into defined logical systems, or can it be reduced to a conditional reasoning where logical connections between premises and consequences are univocal, too (e.g.: if you want x, you have to do y). So, Kohlberg underlines that in moral judgement the gagged ability is firmly connected to the understanding of social rules that are the basis of the building up of relationships between people.

The rationalist tradition, to which Kohlberg seems tightly linked (starting from his direct cooperation with Rawls, a clear representative of contractualistic moral philosophy), tends to regard moral judgement as an intellectual production that has to be analyzed mainly on a logical consistency and formal legitimacy level.

For this reason, too, and getting over Piaget's legacy, Kohlberg underlines the idea of a stage evolution that focuses on the changing of the formal legitimacy of judgement during the development process. The basic idea here is that all the different perspectives the subjects show could meet in a common ground, where the keystone is represented by the general idea of justice, which can be understood and discussed following different patterns. These methods will be closely related to the stage the subject has reached in his/her moral development.

In this way, Kohlberg stresses the topic of the validation of the judgement, while he deliberately overlooks the problem of the de-codification of real positions (transformations and distortions made when

we understand situations in which a decision on reality is needed), because he makes clear that moral judgement only concerns what is inside the frame of aware experience and of personal interpretation of situations.

Those studies affirmed a central relation between cognitive development and moral development, and stated the importance of a higher intellectual level to reach the higher moral stages: and, if no specific study was conducted on the gifted, nevertheless they are supposed to have a privileged position with respect to the theory.

In this approach moral behavior is considered as largely dependent on moral judgement: moral judgement, in fact, is viewed both as a necessary condition (you can't behave fairly if you don't know what is fair), and as a motivating condition (if you really know what is good, this assumes a positive value for your action). Moral education assumes the same possibilities and limits of intellectual education: you can't develop by simply memorizing norms or by repeating prescribed and positively reinforced actions, but is necessary to develop a broader comprehension of nature of rules, difference of perspectives, relations between different aspects, both through intellectual and social stimuli: this was done in the 'just community' approach by Kohlberg and other researchers.

In the meanwhile, other theorists (especially social learning theorists, starting with Bandura & McDonald, 1963) focused on moral behavior as influenced by reinforcement and modeling procedures, and analyzed conditions for the efficacy of such procedures (for instance, characteristics of models and of their behaviors, efficacy of preaching vs. modeling).

Those theorists considered moral behavior mainly in its concrete and social effects, not only as an extension of judgement (as coherence with judgement) as cognitivists do. So, many kinds of 'pro-social' behavior have been considered: such as sharing goods, helping others in distress, acting altruistically by giving time, money and effort for altruistic and social purposes.

### **Developments in discussion on moral development**

Piaget did not suggest a reductionist position. His analysis was better aimed to demonstrate how, even in the moral judgement area, those stadial phenomena show themselves, phenomena that explain the evolution of deep mental structures during the growth. He considered and studied moral thinking because here the occurrence was evident.

On the other hand, Kohlberg reaches a more ontologically cognitive viewpoint as he considers moral thinking as the core of the morality and virtue debate, giving it an explicit value connotation. To him, following Socrates and Plato, understanding is a transformation in the way of living, rather than a mere ability.

To balance this 'hard' position, other supplementary components (and not only the cognitive one) have

eventually appeared in further research, as in Rest's contribution to the discussion.

Rest distinguished four major components of moral behavior: interpreting the situation in terms of how people's welfare is affected by possible actions of the subject; figuring out what the ideally moral course of action would be; selecting among possible outcomes in deciding what is actually to be done; executing and implementing a plan of action (see Rest, 1983, 1986).

*Rest's theory on moral action*

---

#### FOUR COMPONENTS

---

- 1 *Understanding the situation*
  - 2 *Deciding what should, morally, be the right thing to do*
  - 3 *Choosing what to do, among different possibilities and motivations*
  - 4 *Executing and carrying out the action*
- 

#### **Cognitive elaboration of moral judgement**

The de-codification of situations and the awareness of transformations or distortions in the processes that lay between perception and judgement represent a central problem in the social-cognitive perspective. Several contemporary researches have shown the importance of context, cultural condition, choice in the verbs used, availability of distortion mechanisms (as the 'moral disengagement' ones, studied by Bandura) in judgement.

So, moral judgement becomes a complex thematic area, which covers various aspects. The main ones are: understanding and de-codifying stimulus situations, knowing and representing socially learnt rules, elaborating the norms deriving from actual experiences and conflicts, realizing the pertinence of the rules to the situation, applying the right regulations. Again, anticipating the material and/or psychological consequences of one's choices on oneself and on the other people implied, valuing the consequences on the self image and the self-esteem related to personal values and identifications, anticipating the blame, using strategies that protect from blame and from damage of self image (e.g. through 'moral disengagement' mechanisms), developing and using verbal arguments.

Recognizing this complexity does not invalidate the central role of the cognitive angle, widely recognized: moral reasoning is a complex form of human cognition that challenges theoretical models of cognitive science (May, Friedman & Clark, 1996)

Nevertheless, facing this complexity, the simple classical analysis of moral judgement, the one traditionally carried out on Kohlbergian dilemma, seems incomplete and reductive. Rest's model, too, underestimates the complexity in the processes and does not

take into account verbal expressions and their influence on moral judgement.

Many different aspects of cognitive elaboration may be considered: decisions in the moral judgement field are deeply influenced by the kind, quantity and ways of approaching information related to the object (event, situation) we have to value.

For instance, the presence of more information items obliges the subjects to reflect more deeply on the nature of factors that suggest either support for or making an exception to the rule in the considered situation. Even when we apply a well-known moral rule, judgement is influenced both by the rule involved and by the contradicting factors suggesting that an exception may be made (Langford, 1992b). In another research by Wainryb (1991), 80% of the moral evaluations changed in response to informational changes and in all subjects significant relationships were found between the evaluations and the informational assumptions. Cognitive context factors represented by characteristics of moral dilemmas and issues account for substantial variability (for instance, transpersonal dilemmas account for higher stage scores than do personal dilemmas: Teo, Becker & Edelstein, 1995).

Access to specified information and knowledge produces relevant influence on judgement: two crucial aspects are the relationship between actions and omissions and the role given to negligence. When substantial a priori negligence is explicitly provided or can be inferred implicitly from contemporaneous information about the actor, there is a change in moral evaluation, especially in relation to a posteriori outcome information (Enzle & Hawkins, 1992).

Information about the size of the 'job' and intent of offenders is relevant for moral judgement even for convicted offenders (Wolf et al., 1995).

Information is relevant also when judging between intentions and outcomes: the use of the 'conjunction rule' (punishment is related to bad intention and bad outcome) is understood even by young subjects (since 4 years old: Zelazo, Helwig & Lau, 1996); moreover, when outcomes are foreseeable, more mature subjects pay more attention to them (Sanvitale, Saltzstein & Fish, 1989).

Information processing rules and heuristics are also important: judgment for commissions is harsher than for omissions ('omission bias', Spranca, Minsk & Baron, 1991). So, an important effect on cognitive elaboration of moral judgement is provided by the difference between commissions and omissions.

Andreani and Pagnin (1992, 1993, 1994), have underlined that expressing moral judgement involves different cognitive processes: valuing the situation (specifically, roles and needs of the actors) and the immediate or long-term consequences of one's deeds; understanding the rules, which control expectations and define rights and their enforcement field; and affective-emotional processes such as the affective

involvement of needs and consequences committed in the action (particularly in terms of empathy); and the tendency to look after those needs and consequences.

### How to survey moral judgement

Many controversies lay in the way of analysis and measurement of what we define as moral judgement. The main tools in this field have been the Standard Interview (SI), or Moral Judgement Interview (MJI) by Kohlberg, to analyze through the scoring procedure defined by Colby & Kohlberg (1987) and the Defining Issues Test (DIT) by Rest. Those instruments, particularly the SI, so complex and time-consuming, have often been applied in a revised short form, fitted in form and contents to different situations.

Nevertheless, other instruments have been used, such as the Ethic of Care Interview by Skoe and Marcia, the Ethics Position Questionnaire by Forsyth, the Sociomoral Reflection Measure by Gibbs, and many others. In different cases, alternative projects have studied the scoring method used in the analysis of the classical dilemmas, as in the method proposed by Langford (1992a).

On the methodological level, then, researchers have tried to verify the unity of the stadial meaning. For instance, principal axis factor analysis and LISREL were used to test the hypothesis that moral stages form structured wholes (Cortese, 1989): the results supported the idea of moral stages as unitary wholes: a single underlying factor accounted for between issue correlation in moral stage scores: there is a unitary factor across the different context of various dilemmas. Bush, Krebs & Carpendale (1993) also showed that moral judgement was structurally consistent across three sets of dilemmas.

### Controversies about gender and culture bias of moral judgment measures

A classical controversy in this field deals with the relationship between contents classified within different stages and their cultural and sexual definition. Sexual specification has been a crucial point raised by one of Kohlberg's students, Carol Gilligan (1982). She revealed the presence of two main moral orientation, 'care' and 'justice', which appeared in different percentages in the answers of men and women.

Gilligan thought that Kohlberg's traditional scoring clearly favors male orientation to 'justice' rather than female orientation to 'care'. Hence, several studies proved controversial: first Walker then Krebs (Krebs et al., 1991) showed there were no striking differences between male and female subjects, while Baumrind ratifies and makes a thorough study of Gilligan's findings. Again, some researches on adolescent subjects revealed the presence of a more cognitively evolved moral judgement in women.

Perry & McIntyre (1995) point out this phenomenon through the distinction between three ways to make moral decisions: a care mode (others should not suffer), a justice mode (decisions made according to the golden rule), and a narrowly concerned or selfish mode. As the authors say: "All three modes were used by males and females; however, males were more likely to choose the narrowly concerned mode than were females, who chose the justice and care modes more often." Garmon et al. (1996), too, showed that "in moral judgement stage, females were more advanced than males during early adolescence. Care-related and ethically ideal expressions were more prevalent in females' moral judgement. Results reject Gilligan's claim of stage bias, but support was found for gender-related moral orientation differences."

Even more clearly than the disputed sexual difference, cultural tradition has been stated as playing a major role in the definition of moral orientation and in the various aspects considered in its valuation. Even though Kohlberg had found correspondence in the results of the researches led with his method in different countries (Western, Eastern cultures, Northern and Southern cultures of the world), a clear advantage for North-western countries was found, and it aroused several doubts on the fairness of his method.

More recent studies show the nature of cultural influence on moral judgement. For instance, in the Mille & Luthar's (1989) research on Indian and American subjects it is stated that "Indians tended to categorize role-related interpersonal responsibilities as moral issues, Americans tended to regard them in personal terms." Hence, the idea that moral reasoning may be based on role-based interpersonal responsibilities and not merely on justice considerations. Haidt et al. (1993), too, reveal that "cultural norms and culturally shaped emotions have a substantial impact on the domain of morality and the process of moral judgment." Again, Miller & Bersoff (1994) underline that "interpersonal reciprocity is invested with a deontological moral status rather than viewed in purely utilitarian terms in cultures emphasizing interdependent, as contrasted with independent, views of the self."

### The role of situation in moral judgement: abstract judgment and real situation reasoning

An important difference arises between testing and thinking in a real situation. Different researches corroborate this remark: Foster & Sprinthall (1992) find that, when having to decide about abortion in real life, there were no major differences between adolescent and adult women on the level of reasoning that directly assessed the specific decision concerning abortion, while in general test of moral reasoning there were clear developmental differences between the adolescent group and the older groups.

In a quite different life domain, decision making in business, Weber (1996) shows that the type of harm

embodied in a moral dilemma and the magnitude of its consequences significantly influence the moral rationales used in managerial moral decision making.

In decisions relating to real behavior the moral situation is interpreted from the self's perspective prior to a behavioral decision, whereas in the case of evaluation it is construed from the perspective of an observer judging the actor's decision after the event.

This is clearly shown in a social-psychological study from Denton & Krebs (1990), where subjects responding hypothetically attributed to themselves moral integrity, while in a real situation analogous to that of the test, when they were really induced to an illegal behavior, they behaved in a different way.

Other studies show that moral judgments are situation-specific. For instance, Keltikangas (1989) found that in many fields of life, moral cognition of aggressive subjects did not differ from those of their non-aggressive peers: the behavioral choices differ only when specific conflicts arise.

Even studies on incarcerated subjects show that they are not significantly differentiated from controls in moral judgement, when principal social variables (status, education, race, and gender) are controlled.

### **A crucial issue: moral judgement and action**

In Rest's componential model of moral development a separate place is given to executing and implementing a plan of action (component 4), that affects the relationship between belief and action. This component involves 'ego strength' and self-regulation skills; to this aspect are referred the incongruities between moral judgement and behavior observed by many researchers (see Blasi, 1980). For instance, in an often quoted research, Damon (1977) asked young children how 10 candies ought to be distributed as rewards: when these same children actually were given the 10 candy bars to distribute, they deviated from their espoused schemes of fair distribution. And Sobesky (1983) showed that when information about different types of consequences is added even to hypothetical moral dilemmas, as the severity of personal consequences increases, people favor self-interest over principled reasoning.

The radical critics see moral judgement as representative only of fancy talk and argument, of ability in verbal fluency or in elaborating excuses, not of social action and behavior.

In the face of such criticisms, even cognitive theorists recognize that verbal moral judgement does not explain the whole moral behavior. In fact, many studies have been carried out about relation between moral judgement and behavior, using various kinds of measures for behavior: both laboratory measures (like as Prisoner Dilemma Game, cheating in the solution of difficult problems, sharing rewards, etc.) and naturalistic measures (such as systematic ratings in school, clinical ratings, reports of anti-social behavior, delinquency, performance in caring activities by doctors, or

conscientious objectors, etc.). As Rest (1986) remarks, "in general, the finding from these studies is that moral judgement is consistently statistically related to behavior measures, but the strength of the relation is only moderate (approximately a correlation in the 0.3 range)."

To understand the relationship between moral judgement and action, some researchers referred to Ajzen's theory on reasoned action. For instance, Kramer & Hofmann (1990) showed that, fitting moral judgements, behavioral intentions, expected personal consequences, and expected social consequences in the analysis model, the level of moral judgment moderates the prediction of behavioral intentions: so, moral judgement is a moderating factor, but only a partial determinant of behavioral intentions.

Using structural equation techniques, specifically Lisrel path analysis, Lombardo & Pagnin (in work) show that a modified model of reasoned action has to be used, because not only personal moral judgement level but also moral disengagement mechanisms (see Bandura, 1991) result as main moderators upon behavioral intentions. In different types of dilemmas, concerning situations near to everyday life (loyalty to friends, love relationships, bullying and reporting a physical assault to the authority), main components of decision process were investigated: expected outcomes of the intended action, evaluation of such outcomes as positive or negative, representation of reference groups (parents, best friends, and schoolmates) norms about the problem, subjective importance of conforming to those reference groups expectations, personal principles about the problem, moral disengagement mechanisms; behavioral intention and moral stage assessed by classical DIT dilemma were considered. More than 400 students (16–17 year old) were tested.

The model resulting from the use of structural equations as best fitting with data collected from a research on 400 subjects is shown in Fig. 1.

In conclusion, we think it is necessary to maintain a certain distance between judgement and action:

- as a perspective: judgement as a third person evaluation, outside or after the act, action as a first person choice, before the act;
- as a process: while in behavior motivational and affective aspects play their role, in judgement this role is basically given to skills in social reasoning;
- the difference between the two processes is symbolized by two characters, which express the peculiar qualities of each level at the highest degree. The first is the pro-social altruist (that could be the 'saint' or the 'hero'), the second is the 'wise man', able to judge for himself and for the others, more than being only a man of learning or the guardian of law, and he can act in different ways, following various needs and roles. Only a few outstanding people embody both figures.

### MODIFIED MODEL OF MORAL ACTION (Lombardo & Pagnin)

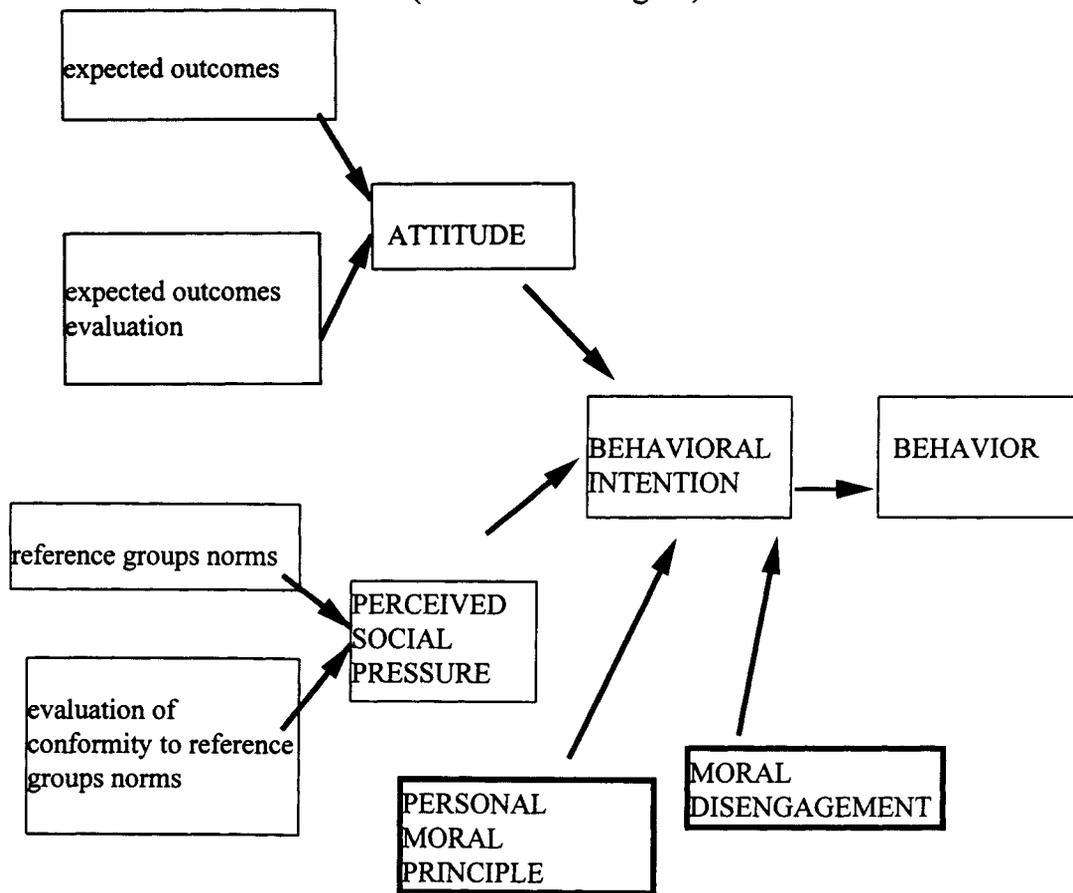

Figure 1.

#### Moral judgement and action: the role of motivation and values

A principal aspect of moral development concerns motives for moral action. In fact, whether a subject is able to apply his or her moral competence to a real-life context seems to be a problem of affectively dealing with personal needs and self-interest in a situation.

Moral judgement is based not only on logic: moral judgement enters into a descriptive account of our emotions, and our emotional responses to situations and to each other necessarily inform the moral judgments. Emotional responses to situations and to others inform the moral judgement.

In this perspective, also, the role of defense mechanisms on moral judgement was considered, embedding moral judgement research within the broader sphere of personality: adolescents with mature profiles of defen-

ses reasoned at higher stages of moral judgment (Hart & Chmiel, 1992). On the other side, moral problems that are overwhelming reflect problems in primary relationships, calling to mind developmentally primitive moral strategies (Blakeney & Blakeney, 1992).

As Bandura (1991) notes, "a person's level of moral judgement may indicate the types of reasons likely to be most persuasive to that person, but it does not ensure a particular kind of conduct . . . different people can arrive at different judgements from the same principle of justness, depending on what factors they consider relevant and how they weight them." From such a point of view, a broader conception of morality requires more than skill in abstract reasoning: affective and social factors play a vital regulative role in moral conduct.

The problem of moral motivation sees the competition of three kinds of theories: emotion centered

theories, rationality centered theories, and social (and self) centered theories.

*A. Emotion centered theories.* Guilt feeling is the first and more traditional reference in psychodynamic theories; but other psychologists also consider it as the basis for moral behavior. Even behaviorists utilized guilt in the same direction, though giving a different interpretation of its origins:

- in psychoanalysis guilt has a wide meaning, from normal remorse to absurd self-rebukes in severe depression. It is an affective state following an action that the subject considers bad; but, as the critical and punitive agent (the super-ego) is differentiated from the conscious self since childhood (in the Oedipal stage), guilt feelings, though tied to the internalization of demands and prohibitions of parents, have a largely unconscious origin and not-rational outcomes (Freud S., 1923); for behaviorists, on the other hand, guilt feeling can be interpreted as anxiety anticipating punishment, or fear of punishment: conditioned negative affect motivates morality (Aronfreed, 1968; Eysenck, 1976);
- a somewhat different emotional state, near to guilt, which has been considered as source for morality, is empathy: Hoffman (1977) considers empathy, and empathy-based guilt as the basis for altruistic motivation. Empathy is defined as “a vicarious affective response that does not necessarily match another’s affective state, but is more appropriate to the other’s situation than to one’s own” (Hoffman, 1984, p. 285): this appropriateness depends on the knowledge about others and self, and definitely on one’s cognitive level. So it is possible to identify some different developmental levels of the empathic distress: Hoffman identifies four levels: global empathy, ‘egocentric’ empathy, empathy for another’s feelings, empathy for another’s life condition (Hoffman, 1991).

*B. Rationality centered theories.* The general nature of moral obligation is seen in the rational necessity of putting oneself beyond the particular:

- in the more abstract and philosophical expression, this is made by the Kant’s categorical imperative, that expresses the general nature of obligation, besides specific, conditional imperatives (like those studied by deontic logic: “if you want x, you must do y”).
- in the cognitive developmental theory of Piaget, obligation comes out from social understanding of how cooperation functions and from one’s own stake in making it work (Piaget, 1932)
- in a similar way, in Kohlberg’s work the origin of moral motivation is seen in the experience of living in just and caring communities: this can lead to understanding how cooperative communities are

possible and to moral commitment (Kohlberg, 1984; the philosophical roots of this conception are exposed by Rawls, 1971)

- impartial cognitive role taking is postulated by cognitive developmental theories as the source of principled reasoning. So rationality dictates morality: it is not possible to do right if you don’t know what is right; and when you know what is right, the need for cognitive equilibrium and the knowledge of general consequence of evil urges you to do right.

*C. Social and self theories.* From classical social learning, according to which people just respond to reinforcement and/or modeling opportunities and learn social behavior (Bandura, 1977), to social cognitive theory, where the role of self and self-regulation mechanisms are included.

- According to Bandura (1991) in social cognitive theory moral conduct is regulated by two major sources of sanctions: social sanctions and internalized self-sanctions. So, people’s belief in their efficacy to exercise control over their own motivation, thought patterns and actions, plays an important role.

But the self is not seen as disembodied from social reality, as social influences affect the operation of the self system in three major ways: contributing significantly to the development of self-regulatory competence, providing collective support for adherence to moral standards, and facilitating selective activation and disengagement of moral self-regulation.

In this perspective, even moral thought is not solely an intrapsychic affair: “impartial role reversibility is imaginable in the abstract, but social experiences create too many human biases for impartiality of view and universalization of interest to be achievable in reality” (Bandura, 1991, p. 48).

- Other researchers consider the role of the self central in moral motivation: concern for self integrity and one’s identity is the main moral agent for Blasi (1985); identification with something great and highly valued as part of the construction of the self has the same function for Erikson (1958).

We can note that social influence affects the operation of the self system in four major ways: contributes to the development of self-regulatory competence, provide collective support for adherence to moral standards, facilitate selective activation or disengagement of moral self-regulation, states the areas and situations affected by moral meanings.

So, in a social cognitive perspective moral judgement is regulated by two major sources: social sanctions and internal processes referring to the self-concept. Moreover, people’s knowledge about their values and feelings and belief in their efficacy of

exercising control over thought patterns and actions plays an important role.

- In a social perspective centered on the self also values and life philosophy have a substantial impact on moral behavior (also more than in moral judgement).

A research shows, for instance, that in adolescents, nominated by community leaders for having demonstrated commitments to care for others or the community, and interviewed on issues of self-understanding, moral judgement, and implicit personality theories, personal beliefs and philosophies are crucial: care exemplars were more likely to describe themselves in terms of moral personality traits and goals<sup>1</sup> (Hart & Fegley, 1995).

Also the acquisition of optimistic values seems to favor moral judgement development: a strong positive relationship between meaning in life and moral judgement levels was found for males and females regardless of education or religiosity, and for criminals and non-criminals (Addad & Leslau, 1990).

### **Discourse and social representations in moral judgement**

Moral judgements are apparent in discourse about most forms of human interaction: what is their content, how are they constructed by language and interaction? Parents provide moral training of their children not only through punishment or approval, but also, primarily, by discussing situations and behavior to be punished or approved. For instance, in the case of aggressive behavior, parents take the lead in promoting their younger son's narrative and logical understanding of his offensive action. The family's court is an important natural moral training ground for the child's acquisition of reasoning, narrative understanding of aggression, critical thinking, and the arguments used in proving a case (see Beck & Wood, 1993).

Discourse can also determine the extent in which individuals construct the situation as moral or non-moral (Smetana, 1994): a business matter, a political matter, or even a friendship matter may become a moral problem and require reasoning and decision, or merely be considered from a 'matter of fact' aspect. Personal language and, moreover, shared language in conversations strongly influences the moral status of a problem: most intelligent children are more sensible to the language expressions, and rapidly identify their implicit consequences. This is also the reason for the importance of media presentations of social problems, as they create a shared language about them.

For many years verbal expressions have been considered crucial in moral judgement research. Kohl-

berg had already shown—even with a pure 'diagnostic' aim in answering classification—the importance of verbal expressions. He observed (Colby & Kohlberg, 1987) how moral domain is characterized by the ways of moral language, and how they express the actions useful to the individual to face the situations of moral conflict. According to Kohlberg, they are: "obeying, approving or blaming, punishing or proving one's innocence, having rights and duties."

In pre-school children, having suitable linguistic abilities is a major condition for being able to discern between morality and behaving (the observance of conventional behavior), (see Smetana & Braeges, 1990), and later, mainly during adolescence, for learning more complex levels in moral judgement. The essential role of linguistic knowledge is confirmed by research in hearing impaired adolescents, that are unable to fully handle reciprocity and equality in a contractual relationship (Sam & Wright, 1988).

Other researchers have given great importance to verbal expressions used by the subjects to understand the application field and the extension of moral judgement in real life. Some of them have proposed an autobiographical collection of real dilemma situations and their subsequent content analysis (Walker, De Vries & Trevethan, 1987; Wark & Krebs, 1996); situations found in these cases are very different in their dilemma intensity and in their creative richness. Others have devoted to verbal and speech characterization of the moral judgement levels, which have been hypothesized by the classical cognitive-developmental theory, when asking, for instance, to describe and typify characters that give morally high judgements. Wygant & Williams (1995) found that subjects describe people using high and moderate levels of post-conventional reasoning, positively in terms of rationality and intelligence but negatively in interpersonal terms (e.g. unfriendly, insensitive, selfish, indifferent, phony, inconsiderate, inhumane), compared to people using low levels of post-conventional reasoning.

Finally, to us a crucial point is the attribution of moral value to problems and the identification of the core of meaning requested by this attribution: on the semantic level, which content presents the moral connotation of a situation, according to people with different life conditions? To answer this question we have used procedures such as lexical analysis to the answers to dilemmas (Pagnin & Zanetti, 1997; Pagnin & Bajoni, 1997), narrative analysis and conversational analysis.

### **Social and professional impact of moral judgment**

It could be stated that the link between social relationship and moral judgement is double: on one hand, positive social experiences favor the development of an evolved moral judgement, as Kohlberg hypothesized (he thought only the experience of a

<sup>1</sup> The differences between subjects and control groups vanished in measures of developmental stages of moral judgement.

supporting community and of the peers gives way to an evolution in moral judgement in young people) and as it has been ratified by specific researches. For instance, adolescent moral judgement is consistently related to reports of positive intra-familial relationships (Speicher, 1992); and children's moral judgements are related to positive social experiences associated with peer acceptance (Buzzelli, 1992).

On the opposite side, the level of morality influences social acceptance: moral characterization of a subject or situation is a powerful element in social categorization, with a strength even superior to traditionally important features as high ability (Martijn et al., 1992).

This awareness led not only researchers working with public and health institutions to carry out surveys on moral judgement, but even company personnel dealing with directors training and marketing (McIntyre et al., 1995).

Moral judgement and the attribution of moral features theme spreads out and involves several fields: from the classical criminology (Przygotski & Mullet, 1993; Gregg, Gibbs & Basinger, 1994), to food behavior (Stein & Nemeroff, 1995), from marketing and company management (Weber, 1996), to medicine (Testa & Simonson, 1996; Reiter & Hiddemann, 1997; Crichton, 1997). Moral judgement can influence many people's behavior: not only law, caring and health workers, but also consumers. That has been clearly shown by the reaction spread out from the accusations made against some sports corporations to exploit young workers in the third world. Or the 'Nestlé affair', related to an evaluation on the negative effects of the dried milk diffusion in some countries of the third world. With this growth of the consumer awareness, company management also have to become involved in this side of company and products image.

Moral dimension becomes an important part in social image of people and even of institutions: we have to consider not only the developmental side (moral judgement seen as a way in cognitive and emotional growth), but also its relevant social impact.

Even in scientific literature, the double soul of this subject—developmental and social—is assessed by the fact that some of the most interesting researches have been published on the one hand in *Child Development* and, on the other, in *Journal of Personality and Social Psychology*, which are two fundamental keystones in their area of study.

### **Specific relationships between moral judgment and high ability**

High cognitive ability and high education are the main contributors to high level of moral judgment: most researches find strongest relations between intelligence (or general cognitive ability) or educational achievement and measures of moral judgement.

Many data were found supporting those assumptions. For instance, years in college are the strongest predictor of moral judgement (Finger, Borduin & Baumstark, 1992); intellectual perspective taking in academic settings accounts for more of the moral judgement variance than does any other factor (Mason & Gibbs, 1993); stages of logical and socio-moral judgement are strongly related to each other (Gibson, 1990). At least, above-average cognitive ability is necessary for higher scores in moral judgement, as higher cognitive achievement ability appears to provide a foundation for higher scores in moral judgment, even if it is not the only element needed (not every high achiever obtains a high score on moral judgement) (Narvaez, 1993); creative gifted give more original solutions to the dilemmas (Andreani & Pagnin, 1993).

Also, researches on personality traits (e.g. referred to the 'big five' model) assess that the element connected to intellectual performance is tightly linked to the level in moral judgement: principled moral reasoning relates to markers of intellectual-academic ability and to the big-five factor of openness to experience: "openness to experience is the big-five factor that best predicts moral reasoning" (Dollinger & LaMartina, 1998: moral reasoning was measured by the DIT; nevertheless, in our research [not published], good correlation was also found with consciousness and sociability).

Intellectually gifted children appear to reach a relatively high stage of moral reasoning earlier than their chronological peers (Karnes & Brown, 1981; Tan-Willman & Gutteridge, 1981). Some may be able to use principled reasoning during mid-teens, while it is normally reached only in adulthood by a small segment of the population. Using the DIT, Janos & Robinson (1985) also found significantly advanced moral judgement (compared with standards) in older gifted students (up to 18 years old).

Other researches underline as reaching a high level in thinking, talking about intellectual stages, is a fundamental pre-requirement for reaching the highest stages in moral judgement in the Kohlberghian sense (see Walker & Richards, 1979). As Walker (1991) states, "moral reasoning is based on, and constrained by, cognitive development: adequate solutions to difficult moral problems require systematic thought and logical analyses." So, advancements in cognitive development place individuals in a state of readiness for moral growth, as they may more easily understand higher moral reasoning and recognize deficiencies in common moral thinking.

Examining the available studies, we see that children and adolescents intellectually gifted generally have better results than their fellow-mates in 'paper and pencil' tests on moral thinking (see Rest's resourceful review, 1986).

Then, we can stress that some personality features in the gifted, shown by Andreani (1975), or by Janos & Robinson (1985), are potentially linked to some

components of moral behavior, as Ego-strength and the ability to implement the correct course of action (see component four in the Rest's model).

Andreani (1975), examining personality of gifted adolescents through projective tests such as Rorschach, found that the ones that combined high intelligence with creativity were characterized by apparently conflicting traits: empathy, emotional reactivity, strong drives for aggression and sex (even if usually well controlled), low conformity, high need for achievement.

We also notice that features such as aggressiveness, competition and a great ambition for individual success (see Freeman, 1991), which could give way to anti-social behavior, may be bent to socially positive directions; for instance, towards creative aims, or, at least, trying to excel in one's social and professional duties. We shall remember that, from the 'morality of responsibility' point of view, being suitable to do one's social duty (so, one's professional fulfillment) is one of the basic aspects in the moral behavior of a rational type (aimed at enhancing common wellness). Such a statement is validated also on the empirical and factual side, where we notice a positive correlation between high scores in moral judgement and the existence of success orientation in one's job, in civic duties, career fulfillment, educational orientation, civic political awareness (Rest, Deemer, et al., 1986).

Moreover, even if the gifted tend to face to adults and to socially superimposed rules, they do not act in an anti-social way, as they typically conform to reasoned expectations and engage in cooperative relationships.

On the other hand, we note that findings regarding favorable social adjustment come from studies of moderate rather than extremely gifted children: the most talented are more vulnerable, as they are 'out of synchrony' with others (Janos & Robinson, 1985); as Freeman (1985, 1991) notes, highly gifted children are particularly sensitive and reactive to social stimuli they meet, and so are exposed both to most positive, highly intellectually and socially developed experiences, both to negative ones; and their development is inhibited—at any level—without adequate material and psychological conditions. Such susceptibility to environmental conditions show the importance of sustaining interventions, both in the intellectual and in the personality domain; as Heller notes from the experience of his very large Munich Longitudinal Study on gifted students, the "prejudice that the gifted do not need any special support or counseling belongs to those assumptions which have been empirically proven incorrect" (Heller, 1992).

Andreani & Pagnin (1992, 1996), in works on large samples of students, which used Kohlberg's and Rest's concepts and utilized various kinds of tests, showed that gifted, compared to other students, give higher approval of abstract and general principles (post-

conventional in the sense of Kohlberg) and with respect to law and contracts and higher coherence of reasoning; and give less importance to other people's opinion and agreement, and also to sentimental-humanitarian expressions, which constituted the basis for a more intuitive morality in the lower ability groups.

On the basis of these results, we proposed a two-level method of moral judgement: a morality of sentiments (based on common sense and sympathetic feelings) and a rational morality (centered on rational principles and the attempt to weigh the consequences of actions): the first one more typical of average and low intelligence subjects, the second one of the gifted. While the first adheres to common standard, the second requires a calculation of benefit of different actors, a forecast of the outcome of actions, a balance of the different aspects of rights, an examination of different possible roles to be assumed (Andreani & Pagnin, 1992). Besides this general characteristic, in the gifted two different patterns of moral orientations can be identified, where there are important differences in the contents and in the values involved in judgements (Andreani & Pagnin, 1996). In fact, focusing on logical coherence and on personal needs (for instance need for achievement), some subjects tend to neglect the immediate feelings of empathy and the common moral immediate references.

### The Moral Giftedness problem

The idea of moral giftedness involves several levels, which could invalidate the nature of giftedness. In fact, this has been traditionally valued on the basis of the shifting aside from the mean in tests on abstract reasoning or a group of tests including verbal, numerical aspects, deductive abilities (as matrices), and tests on creativity, mainly regarding verbal performance, and of more uncertain validity.

We have not normally considered social ability as an independent variable, for which good measurement exist, and the emotional one, stressed but not defined in a univocal way or by those positions that have recently enhanced the so-called 'emotional intelligence' (a somewhat contended definition). Goleman (1995) cites narrative cases of exceptional ability in resolving social conflicts and potentially dangerous interpersonal or public situations, among children and adults.

There is a common recognition of the existence of such kind of people: in many cultural traditions they are pointed out as models, at least if their actions are congruent with values and discourses of that tradition. Of course here we do not think about mere intellectual ability (the intelligent killer is a well-known figure in fiction literature, but sometimes exists in reality), nor about the kind of social ability we see in the successful politician or salesman, or even in the able cheater: here social ability is really partial and limited, and sometimes is accompanied by quite bad personal and social adjustment. Emotional ability implies a more profound

interest in other people feelings, in their happiness or physical and psychological suffering. The affective side of moral judgement and behavior is crucial here. But also crucial is the ability to communicate and participate in the reasons of choices and decisions: moral judgement requires a high level of (at least, potential) exchange of reasons and motives.

### Enhancing moral judgment in the gifted

The development of morality needs a positive context to enhance cognitive, social and emotional aspects of morality. Both Berkowitz (1985) and Keller & Reuss (1985) underline the importance of communication in moral development. To them, the moral judgement ability is linked to experiencing speeches and discussions about decisions: "The child must acquire the ability to express his or her own needs, interests, feelings and convictions, and at the same time to consider the claims of others. How adequately the child is able to do this depends on two factors: first, on the latitude of unconstrained discussion in factual communication and life practice, as well as in the context of institutionalized learning processes; second, on the child's level of development." (Keller & Reuss, 1985, p. 121).

To be at liberty to form an opinion, to justify it, and to come to terms with possible objections, is something the child learns only when given a fair chance, as a member of a relaxed discourse community, where the child can experience directly what it means to be involved in the tension of an ongoing communication process based on real life experiences. The moral discourse involves the goal of coming to a justified agreement, that is, an agreement shared by those concerned, beyond the 'prima facie duties'.

In fact, cognitive-developmental oriented researchers used communication, discussion and cooperation to enhance moral development: Kohlberg himself conducted interventions based on the 'just community' approach to moral education (see Kohlberg, 1984), where such principles were applied. This theory emphasizes the role of a good social context for moral development: but this does not mean a mere mechanical transmission: even an apparently deprived or antisocial social context may allow the main experiences that enhance significant social exchange about values, life experiences, responsibilities and decisions. But an external intervention will emphasize more direct ways to do it.

The efficacy of interventions in enhancing levels of moral reasoning is pointed out by many researches (for instance Erikson et al., 1976; Whiteley, 1982; Willging & Dunn, 1982): a good review of them (comprehensive of unpublished dissertations) is in Rest & Thoma, 1986, that conclude the meta-analysis stating that "moral education programs emphasizing dilemma discussion and those emphasizing personality development both produce modest but definite effects." (Rest

& Thoma, 1986, p. 85). More recently, positive results of intervention have also been found by Keen (1990).

As Rest states, to obtain measurable results interventions must be long enough (at least three weeks); and these results are probably linked to cognitive pre-requirements and role-taking skills owned by the subjects, like the ones shown by Walker (1980) (see Rest & Thoma, 1986, p. 86).

The exclusive over-emphasis put by cognitivist authors on the main role of cognitive conflict as a stimulus to the development of moral thinking has been discussed by researchers who also investigated other aspects of social interaction, which can boost the development of moral judgement. For instance, Walker has studied the influence of parents on moral development of their children, using a sophisticated analysis of the relationship of the family taken as a whole (thanks to micro-analytical methods applied to interactions). He has revealed that "children who evidenced the greatest development had parents who provided the stimulation of a relatively high level of moral reasoning as well who engaged in behaviors such as eliciting the child's opinion, asking clarifying questions, paraphrasing, and checking for understanding" (Walker, 1991). Those are typically cognitive interventions, but Walker notes that parenting behavior predicting the greatest development also entails supportive interactions, while the least moral development involves affectively conflictual interactions (Walker & Taylor, 1991).

Many authors have expressed doubts on the efficacy on interventions based on rational aspects only, and particularly on the discussion of dilemmas (hypothetical or real-life). We note, for instance that the usual cognitive interventions succeed much more in theoretical moral judgement than in moral discussions of real-life arguments (Villeneuve-Cremer & Eckensberger, 1985).

Critics remark that the constructivist educational intervention is based on the function of cognitive conflict in development. The strategy in order to induce cognitive conflict is discussion, involving comparison and contrast: but it is not clear whether the discussion strategy will suffice for moral growth, as it works for cognitive growth. Nevertheless, it seems the best way of intervention where it is not possible to act on the primary socialization quality and on the presence of strongly positive models in the community.

The ways of intervention may favor development at least in the aspect concerning skills implied in moral judgement:

- understanding the complexity of working of social rules (e.g. reciprocity, agreement, balance);
- understanding the domain of attribution of moral quality to a decision or an action (and of attribution of responsibility or guilt) in the social interaction;
- foreseeing the application to oneself and to the others and its danger level;

- understanding and using argumentative rules useful to comprehend other's point of view and to compare them to one's own (e.g. not being contradictory, accepting deductions, recognizing the link cause and effect);
- anticipating the consequences of the moral attribution on the self-image (on its wholeness and articulation) and the effects on the self even at an emotional and implicit level.

The attention on the ability aspect seems particularly profitable in the gifted and in the age of the maximum development in cognitive abilities: adolescence.

An educational program for social and moral abilities enhancement in selected groups of gifted adolescents was carried out by Pagnin and Zanetti (1997): it was based on exercises of dilemmas discussion, role-taking, social inferences, free expression of personal values, social behavior strategies discussion and dramatized simulation. The outcome of such intervention, analyzed by classic stage scores analysis and by an analysis of verbal expressions and meanings, showed the reaching of higher moral reasoning level.

The aim of the intervention was to enhance four main dimensions:

- general social-cognitive abilities: understanding other people's intentions, feelings and expectations;
- values understanding and selection in social context;
- identification of specific norms for different social domains;
- strategies for pursuing goals.

A set of exercises was used to enhance those abilities:

- discussion of hypothetical dilemmas;
- analysis of intentions, personal values, personality traits of the actors who play different roles in dilemmas, in comparison with one's own values and personality;
- role-taking concerning the different characters;
- identification and description of different aspects and components of real life dilemmas and of life events in one own life, and discussion on such dilemmas;
- expression of personal values, life goals, events which elicit happiness or sufferance, and which produce self-fulfillment or self-blame feelings in personal life;
- social behavior strategies and moral disengagement strategies discussion and dramatized simulation.

We point out also the possibility of using new means to foster moral development: a first experience in the use of computer simulation has been performed by Sherer (1998).

### Conclusion

Summarizing our considerations, we look at moral development as a multi-dimensional construct that

involves some principal social-cognitive abilities, concerning:

- comprehension and evaluation of the situation or problem in its cognitive-social aspects: in particular, the ability to understand other person's intentions, feelings and expectations;
- experiencing empathy with other person's (or living being's) state, and positive feelings toward basic social relationships;
- understanding norms and rules, and the conditions for their selection and use in social context and in specific areas;
- identifying a specific course of action that optimizes the outcomes in terms of social, cognitive and affective requirements;
- eliciting strategies for pursuing and sustaining the selected course of action notwithstanding obstacles.

From such a point of view, moral judgement requires more than skill in abstract reasoning: a specific social experience and a social construction of moral expectations, values and meanings is needed.

In the face of those problems, the classic Kohlbergian approach focuses on judgement legitimization in terms of just-unjust: his rationalist point of view, rooted in a Platonic (even more than Kantian) conception and mediated by the philosophical contractualism of Rawls (opposed, for instance, to the utilitarianism of Hare), consider moral judgement as a form of thinking to be analyzed at the level of logical coherence and formal legitimization. Kohlberg's approach neglects the problem of situation decoding: he explicitly states that moral judgement concerns only what is circumscribed by conscious experience and personal interpretation of the situation.

On the contrary, a social cognitive approach notes that 'a person's level of moral judgement may indicate the types of reasons likely to be most persuasive to that person, but it does not ensure a particular kind of conduct. . . different people can arrive at different judgements from the same principle of justness, depending on what factors they consider relevant and how they weight them' (Bandura, 1991): but it does not give account for the evidence of a development in moral judgement with age and experience, and for the effect of such development on behavior.

On the basis of those considerations, we think that two problems have to be faced in the study of moral judgement:

- on the one hand, moral judgement has to be analyzed not only by a stage-driven codifying system, but also at a more 'ecologically social' level, by analyzing semantic aspects of reasoning about problems
- on the other hand, moral judgement has to be studied as an ability which has some roots in the quality of basic social relationship and trust, and is supported and enhanced by social discussion.

Regarding this second aspect, we think that the working group is a context that contributes to the aim of enhancing moral reasoning and expression. We mean a context where people are at liberty to form an opinion, to justify it, and to come to terms with possible objections; it is something the young person (and especially a young gifted) learns as a member of a relaxed discourse community, where the young can experience directly what it means to be involved in the ongoing communication process based on real life experiences.

In the working group, the moral discourse involves the goal of coming to a justified agreement, that is, an agreement shared by those concerned, beyond the 'prima facie' duties'. Group discussion focuses rational justification of values. During the discussion of moral dilemmas, persons are asked to put into discussion their choices: those are not simply accepted, but must be justified: behind the tolerance for different ways of reasoning, there is a clear understanding that moral criteria are not equally sustainable in the discussion, both on an intellectual basis and on affective-emotional basis.

Intellectually gifted children and adolescents are mainly open to this kind of intervention, as they can better recognize the value of a good reasoning context. Nevertheless, social and emotional aspects also have to be considered: developing good basic relationships, identifying with positive adult models, being exposed to language, discourses and values giving meaning to life.

A specific giftedness in social relationship management could and should be fostered: this should include moral judgement ability and general moral development. Special attention to this aspect should give a broader education to the gifted and favor a more open and positive social representation and social appreciation of the gifted.

# Programs and Strategies for Nurturing Creativity

Arthur J. Cropley<sup>1</sup> and Klaus K. Urban<sup>2</sup>

## Creativity and Giftedness

Almost from the beginning, modern research on creativity, intelligence, and achievement showed that although, as a group, students with high IQs obtained good grades both at school and university, they were consistently outstripped by those with not only a high IQ but also high creativity (e.g. Cropley, 1967a, 1967b). In Sierwald's later (1989) longitudinal study, students with high creativity surpassed those merely high on intelligence at all levels of school. Hudson (1968) showed that students admitted to Cambridge University on the basis of a creativity test graduated with grades equal to those of students selected on the basis of extraordinarily good high school marks. Gibson & Light (1967) and Bayer & Folger (1966) found that many gifted scientists had IQs below 130. More recently, Facaoaru (1985) showed that gifted engineers displayed not only high ability in knowing, recognizing, recalling and reapplying, but also in seeing possibilities, discovering problems, branching out, or inventing. Taken together, these findings indicate that a combination of intelligence and creativity defines giftedness. This is already the case by Grade 7, and increases through school, university and later career.

In accordance with this conclusion, creativity and intelligence will be regarded here as integral elements of giftedness. Referring to research in the former Soviet Union, Matyushkin (1990) supported this approach. Writing in a Western European context, Cropley (1995) regarded creativity as indispensable for 'true' giftedness, and in the United States Sternberg & Lubart (1995) concluded that 'contrarianism' (a combination of cognition, motivation and personality) is a characteristic of all gifted individuals. Hassenstein (1988) argued that a new term is needed to refer to intellectual giftedness, since 'intelligence' is too narrow, and suggested *Klugheit* (cleverness), arguing that this incorporates both intelligence (e.g. factual knowledge, accurate observation, good memory, logical

thinking, and speed of information processing) and creativity (e.g. inventiveness, unusual associations, fantasy, and flexibility).

Ward, Saunders & Dodds (1999) identified two major approaches to conceptualizing the relationship between giftedness and creativity: According to Renzulli's 'three ring' approach (e.g. 1986), creativity and intelligence – together with motivation – are separate *sub-components* of giftedness. By contrast, according to the *overlapping skills* model gifted achievement and creativity require some of the same cognitive skills such as problem definition, selective encoding, shifting context, or transcending limitations (Finke, Ward & Smith, 1992; Sternberg & Lubart, 1995). Cropley (1999a) adopted a somewhat different approach, arguing that *production of novelty* (the central element of creativity) is one possible 'style' for applying intellectual ability, *production of orthodoxy* (at the core of intelligence) another. These two styles are possible at all levels of ability, so that the difference is qualitative rather than quantitative. Production of novelty leads to gifted achievement when the novelty is 'effective'. Such achievement has a quantitative aspect, since high levels of specific and general knowledge, a strongly developed connection to reality, well-grounded self-evaluation, a superior grasp of what the surrounding environment can tolerate, and a high level of command of a medium of expression and communication are necessary for effectiveness.

## The Process of Creativity

Despite what has just been said, a definition that places less emphasis on products is particularly fruitful for discussions of creativity in children. They do not possess the years of experience that are almost always necessary for acclaimed products, even in the case of extraordinary precocious geniuses like Mozart (Howe, 1990), and, in fact, most of them will never produce acclaimed works. Calls for the fostering of creativity in the classroom should not be based on the desire to force an élite group of extraordinary children to exceptional achievements, but on the humanistic goal

<sup>1</sup> University of Hamburg, Germany.  
E-mail: cropley@bold.net.au

<sup>2</sup> University of Hanover, Germany.

of fostering the fullest possible development of all children in all aspects of their personality. An approach based on the *process* of creativity rather than its products is most appropriate for this.

### *Producing Novelty*

The only constant factor in all definitions of creativity is novelty (Morgan, 1953). This was later defined in a more psychological way by Bruner (1962) as the achieving of 'surprise' in the beholder. However, surprisingness alone is not sufficient. Genuine creativity requires two further elements: *relevance* and *effectiveness* (Bruner, 1962). Thus, creativity is nowadays widely defined as the production of relevant and effective novel ideas (Engle, Mah & Sadri, 1997; Cropley, 1999a). In addition, as Grudin (1990), among others pointed out, the purpose of fostering creativity is not self-aggrandisement or exploitation of other people, but promotion of the common good, i.e. it has an ethical element.

### *Solving Problems*

An important aspect of problem solving is the distinction between 'solving' by eliminating a difficulty or removing an impediment and 'solving' in the sense of envisaging, posing or formulating questions that need to be raised in order to deal more effectively or elegantly with an existing situation. The latter is referred to as 'problem finding', and is proactive and constructive rather than reactive and destructive, since it involves bringing into existence a new way of looking at the issue in question. Tardiff & Sternberg (1988) stressed the importance in creativity of *sensitivity to problems*, especially finding 'good' problems. This is more closely related to creativity (see above) than 'merely' solving them (Jay & Perkins, 1997). A striking example (Fromm, 1998) is Einstein's recognition that existing theories of electrodynamics were inadequate, which led to the theories of relativity. A further aspect of creative problem solving involves the ability to *recognize a solution* (e.g. Ghiselin, 1955), even if it falls outside traditional boundaries.

Teachers are accustomed to specifying the problems on which students are to work, laying down the procedures to be used in solving the problems, and defining the criteria for deciding on the value of solutions. However, creative students need to take responsibility for at least some of these aspects. One attempt to promote creativity through problem solving is Creative Problem Solving (CPS) which has a long tradition in the United States (Feldhusen (1993), and has widely and successfully been applied since Parnes (1967). It involves the following steps:

- (1) Mess finding
- (2) Data finding
- (3) Problem finding
- (4) Idea finding

- (5) Solution finding
- (6) Acceptance finding.

### **What Must be Fostered?**

#### *Appropriate Thinking Skills and Strategies*

The initial approach to describing creative thinking was based on Guilford's (1950) distinction between convergent thinking (finding the single best answer) and divergent thinking (generating alternative possibilities). Subsequently, the process of branching out was described in terms of remote associations to stimuli (Mednick, 1962), or linking domains of meaning (e.g. 'bisociation'; Koestler, 1964). In the present chapter, thinking is regarded as a process that uses existing information to produce further information. In the case of creativity, this further information contains effective novelty. This involves *analyzing* the particular form of the problem, *selecting* from among the masses of information available at any moment, *relating* new information to what is already known, *combining* elements of new and old information, *evaluating* newly emerging combinations, *selectively retaining* successful combinations, and *communicating* the results to others.

Although some authors argue that novel combinations result from random associations (e.g. Simonton, 1988), Resnick (1987) emphasized that thinking must be guided by 'executive' processes. Otherwise, creativity would become blind trial and error. A related approach focuses on 'heuristics'. These consist, on the one hand, of rules or techniques for recognizing from the start blind alleys or their opposite, particularly promising lines of attack, and, on the other, of evaluation skills for determining the progress that has been made and how the present approach should be altered (if this proves necessary).

Executive processes and heuristics are part of what is often referred to as 'metacognition' (Sternberg, 1988), that allows people to keep track of their own thinking. It includes review of knowledge, organization of attention, and marshalling of resources. Further metacognitive processes include defining the problem, selecting an appropriate set of processes for solving it, and combining these into a workable strategy. To these can be added evaluation of one's own progress, effective changing of course should the evaluation make this necessary, and identifying of one or more promising alternatives.

Martinson (1995) identified two 'strategic dispositions' in thinking: Some people consistently seek to deal with the new by reapplying existing knowledge and solution strategies, whereas others recognize the need for new ways of dealing with new situations. The nature of this disposition can be clarified by borrowing from Piaget and emphasizing *assimilation* and *accommodation*. Assimilation involves fitting new information in with existing cognitive structures,

accommodation is based on recognizing that current structures are not adequate. Intuitively, production of novelty (creativity) is related to accommodating, sticking to the known (intelligence) to assimilating.

#### *General and Specific Knowledge*

Broad general experience leads to *knowledge*, often obtained outside school and possibly without conscious awareness. This serves as a source of ideas, and is thus favorable to the production of novelty. Thus, linking learning outside the classroom with school learning enhances the chances of creativity. However, thinking alone will not lead to creative excellence, since creativity does not occur in a vacuum but in a particular field: Guilford himself pointed out that divergent thinking seems not to be a general trait, but changes with different contents and specific tasks. Brown (1989) emphasized that area-relevant knowledge and skills are fundamental to creativity. Walberg & Stariha (1992) also emphasized the central role in creativity of relevant knowledge, accompanied by sensitivity to gaps in this knowledge. Henle (1974) regarded the urge to fill such gaps constructively or elegantly as the primary motivation for creativity. In keeping with this view, increasing attention is being given nowadays to domain-specific knowledge—what Feldhusen (1995) called the ‘knowledge base’—as a prerequisite for generating creative ideas and products.

These findings indicate that fostering creativity in schoolchildren would require promotion of:

- rich and varied experience in many different settings
- a fund of general knowledge
- specialized knowledge
- an active imagination
- analyzing and synthesizing skills
- skill at seeing connections, overlaps, similarities and logical implications (convergent thinking)
- skill at making remote associations, linking apparently separate fields (bisociating), and forming new gestalts (divergent thinking)
- preference for accommodating rather than assimilating
- ability to recognize and define problems
- ability to plan one’s own learning and evaluate progress (executive or metacognitive abilities).

#### *Creativity Facilitating Personality Factors*

Reviews of the relevant research (e.g. Eysenck, 1997) typically list autonomy, non-conformity, openness to stimuli, flexibility, tolerance of ambiguity, inner directedness, and ego strength, among others, as favorable for creativity. However, Helson (1996) concluded that there is no unitary personality profile that is both typical of highly creative people as a group and also distinguishes them from the less creative. According to an early study (McMullan, 1978), creativity requires possession of a ‘paradoxical’ personality. This is characterized by ‘polarities’ such as openness com-

bined with drive to close incomplete gestalts or acceptance of fantasy combined with maintenance of a strong sense of reality. More recently Csikszentmihalyi (1996) emphasized the importance of a ‘complex’ personality, combining, among others, sensitivity with toughness, or high intelligence with naivité. Striking is that the personality characteristics regarded as important for creativity are often contradictory: for instance, the creative personality is simultaneously stereotypically ‘masculine’ (autonomous, self-confident, tough) and yet stereotypically ‘feminine’ (sensitive, intuitive, responsible). These findings imply that both rigid maintenance of strict gender roles as well as insistence on a well-balanced or harmonious personality would inhibit creativity. An ‘integration of opposites’ (Urban, 1995a, 1997) seems necessary.

Fostering creativity thus requires promotion in children of:

- openness to new ideas and experiences
- adventurousness
- autonomy
- ego strength
- positive self-evaluation and high self-esteem
- acceptance of all (even contradictory) aspects of one’s own self
- preference for complexity
- tolerance for ambiguity.

#### *Motivation for Creativity*

It is intuitively obvious that the acquisition of comprehensive and detailed area-specific knowledge and skills (see earlier discussions of the knowledge base) requires disciplined task commitment and a high level of persistence. The problem in question and the connecting thematic field have to be maintained as the focus of attention over a long period of time and with varying intensity (Hayes, 1989). Concentration and selectivity are necessary for collecting, analysing, evaluating, and elaborating information and data. In fact, studies of highly creative people have demonstrated the importance of dedication almost to the point of obsession (e.g. Biermann, 1985; Csikszentmihalyi, 1988). At a more everyday level, Baldwin (1985) argued that intense motivation for activity in a particular area may be the best indicator of creativity in members of disadvantaged groups.

The creation of novelty requires readiness to diverge, defy conventional opinion, or expose oneself to the possibility of being wrong: in other words, taking risks (e.g. Williams, 1976). Basadur & Hausdorf (1996) emphasized the importance of placing a high value on new ideas. Early research in aesthetics as well as Gestalt psychology showed the importance of preference for complexity in creative people, and this was confirmed by Shaughnessy & Manz (1991).

A widely accepted position is that creativity is based on intrinsic motivation (Amabile, 1996), the wish to

carry out an activity for the sake of the activity itself. This can be contrasted with working for external rewards, such as praise, prizes, even avoidance of punishment (extrinsic motivation). More recently, however, the possibility of fostering creativity in the classroom by the application of external rewards has been demonstrated by Eisenberger & Armeli (1997). They showed that extrinsic reward led to enduring improvements even in a creative area such as music, when children were rewarded for specific 'creative' behaviors such as incorporating unexpected elements or producing alternative possibilities. Thus, children need a clearly-defined concept of creativity.

Cropley & Cropley (2000) extended this by showing that engineering students who received a concrete definition of what was meant by 'creative' in a particular class, and were counselled individually on the basis of a personal profile of their own specific strengths and weaknesses, were more original on creativity tests, and built more creative models in a laboratory exercise, despite the fact that they were working for grades.

The findings just presented suggest that teachers should seek to foster in students

- a concept of creativity and a positive attitude to it
- curiosity
- willingness to risk being wrong
- drive to experiment
- task commitment, persistence and determination
- willingness to try difficult tasks
- desire for novelty
- freedom from domination by external rewards (intrinsic motivation)
- readiness to accept a challenge
- readiness for risktaking.

#### *A Supportive Environment*

A product must be communicated to other people and at least tolerated by them ('sociocultural validation') if it is to be acclaimed as creative. What Csikszentmihalyi (1996) called a 'congenial' environment is vital. In schools, this means that the atmosphere or climate of the classroom is of major importance. Where the teacher and classmates reject differentness or non-standard solutions, the environment will inhibit creativity.

The result is that creativity requires on the part of the creator:

- independence and nonconformity
- knowledge of the social rules
- courage
- ability to communicate.

On the part of the social environment, creativity requires:

- acceptance of differentness

- openness and tolerance of variability
- renunciation of rigid sanctions against (harmless) mistakes
- provision of a 'creativogenic' climate.

#### *Creativity Fostering Teacher Behavior*

Early in the modern era, Feldhusen & Treffinger (1975) reported that 96% of teachers believed that creativity should be fostered in the classroom. However, even in Grade 2, children who scored highest on tests of creativity were rated by their classmates as the ones most often in trouble with their teachers (Stone, 1980). In fact, studies both in the United States and elsewhere have shown that many teachers dislike the characteristics and behaviors associated with creativity (e.g. Howieson, 1984; Obuche, 1986), despite their theoretical support of it. Nonetheless, 'creativity fostering' teachers are particularly good at promoting students' creativity (Cropley, 1992). They provide a model of creative behavior, reinforce such behavior when pupils display it, protect creative pupils from conformity pressure, and establish a classroom climate that permits alternative solutions, tolerates constructive errors, encourages effective surprise, and does not isolate nonconformers.

Clark's (1996) research on teachers who had been rated as particularly successful with gifted children made a direct link between giftedness and creativity: These teachers, among other things, emphasized 'creative production', showed 'flexibility', accepted 'alternative suggestions', encouraged 'expression of ideas', and tolerated 'humor'. They were themselves creative, and had stronger personal contacts with their students.

Creativity fostering teachers are those who:

- encourage students to learn independently
- have a cooperative, socially integrative style of teaching
- do not neglect mastery of factual knowledge
- delay judgment of students' ideas
- encourage flexible thinking
- tolerate 'sensible' errors
- promote self-evaluation
- take questions seriously
- offer opportunities to work with varied materials under different conditions
- help students learn to cope with frustration and failure
- reward courage as much as being right.

#### **Instructional Resources for Fostering Creativity**

Treffinger, Sortore & Cross (1993; first edition of this handbook) reported in excess of 250 published materials that can be regarded as instructional resources for fostering creativity. Huczynski's (1983) encyclopedia of methods listed dozens that could be applied to

nurturing creativity in schoolchildren, including 'buzz groups', 'flexastudy', 'lateral thinking', and 'mathetics'.

Some consist of simple, specific games, such as 'bridge building', 'idea production', or 'creative connections' (Cropley, 1992). Others involve mental techniques that can be learned quickly and then applied in a wide variety of settings as general ways of getting ideas, such as the *SCAMPER* procedure, originally developed by Osborn. This approach assumes that production of novelty simply involves changing what already exists, and includes seven change techniques: substituting, combining, adapting, magnifying, putting to a different use, eliminating and rearranging/reversing.

Other procedures are more formal, but still consist of specific procedures that can be learned and then applied in many different situations, usually in order to get ideas (e.g. *Synergetics*, *Brainstorming*, *Morphological Methods*, *Bionics*, *Imagery Training*, *Mind Maps*, the *KJ Method*, or the *NM Method*). Most of these are described by Torrance (1992) or Michalko (1998). Although they are suitable for use with schoolchildren, they are often applied in business, for instance in product development, or in advertising.

Probably the best known of all these is *Brainstorming* (Osborn, 1953), which has become the prototype for a number of related techniques. 'Classical' *Brainstorming* is a group activity in which each member is encouraged to put forward ideas without any constraints, no matter how implausible the idea. Criticism is not permitted, because of its inhibitory effect. Quantity of ideas is important, rather than quality, and 'hitchhiking' by attaching one's ideas to those of others is encouraged. There are various procedures for selecting, recording, testing and otherwise ultimately relating ideas to reality. In the *KJ Method*, individual members of the group write on cards their ideas for defining the core of the problem at hand (one idea per card). The cards are then sorted into 'sets', i.e. groups of cards containing similar statements defining the nature of the problem, and the different sets are given labels which summarize the essence of the problem. Sets of solutions are then constructed in a similar way.

Some procedures retain the idea of unhindered production, but go beyond simple 'blind' generating of ideas. In *Mindmaps*, for instance, the central theme is written down and then a 'spray' of associations recorded, each association functioning as the beginning of a new spray of further associations. Solutions are found by identifying patterns or threads found in the masses of associations. The *Hierarchical Method* (e.g. Butler & Kline, 1998) involves an even stronger element of organization and structure. Although the idea of generating large numbers of possible solutions is retained, this approach is based on the idea that a hierarchical organization of ideas (rather than simple masses of ideas or associational chains) produces

solutions of better quality. Suggested solutions are sorted into classes on the basis of common content. Subsequently, hierarchies can be formed by combining lower level classes into superordinate classes, or by contrast, by breaking down higher order classes into lower level categories.

Many of the instructional resources now available involve *programs*—often based on a model of creativity, and sometimes with substantial special materials—that are used systematically over a period of at least several weeks (for instance, a school term or year) with the intention of inculcating a general disposition to be creative. (Such programs often include training in various techniques.) The United States Patent and Trademark Office (1990) listed about 25 such packages, and Treffinger, Sortore and Cross briefly described a number of them. A number of examples of programs of this kind are summarized in Table 1.

#### *Popular and Commercial Programs*

In addition to more scientific works on fostering creativity, there is a substantial number of semi-scientific or popular publications with essentially commercial goals aimed at organizations (business/commerce, the armed forces, government) and individuals (adults interested in self-help, teachers, parents). Many of these were developed by practitioners, not necessarily researchers or even traditional educators. Probably the best known are deBono's publications, in which he has elaborated the concept of 'lateral thinking' (e.g. deBono, 1970). Originally a medical practitioner, he has developed not only a graphic and picturesque terminology (e.g. 'water' and 'rock' logic), but has also published the *CoRT Thinking Program* (deBono, 1978), a set of strategies for creative thinking that has been widely applied in business and education. Michalko (e.g. 1996, 1998), a former officer in the U.S. Army, has recently become prominent in the USA, with programs such as *Thinkertoys* (aimed at nurturing business creativity), or *Cracking Creativity* (self-training).

Such books are often based on scholarly findings, even if the connection is sometimes loose. They are frequently technically well-produced, extremely readable, easy to understand, and plausible. In addition, they often contain sensible and humane advice with which very few people would disagree, and many of them are undoubtedly capable of bringing benefits.

However, there are problems with much of this popular literature, and these were summarized by Hruby (1999)—he was reviewing a specific book, but his comments are very pertinent and can be applied here in a more general way. He complained that enthusiasm for educational reform can 'run away with itself' (1999, p. 326). Among other weaknesses, he identified: presenting speculations, conjectures and hypotheses as established facts; confusing correlations

Table 1. Main characteristics of well-known creativity programs.

Program	Level	Materials	Aimed at Promoting
Imagi/Craft	Elementary School	Dramatized recordings of great moments in the lives of famous inventors and discoverers	<ul style="list-style-type: none"> <li>• The feeling that their own ideas are important</li> <li>• Widened horizons</li> <li>• Career aspirations of a creative kind</li> </ul>
Purdue Creative Thinking Program	Fourth Grade	Audiotapes and accompanying printed exercises	<ul style="list-style-type: none"> <li>• Verbal and figural fluency, flexibility, originality, and elaboration</li> </ul>
Productive Thinking Program	Fifth and Sixth Grades	Booklets containing cartoons. Uses principles of programmed instruction	<ul style="list-style-type: none"> <li>• Problem-solving abilities</li> <li>• Attitudes to problem solving</li> </ul>
Myers-Torrance Workbooks	Elementary School	Workbooks containing exercises	<ul style="list-style-type: none"> <li>• Perceptual and cognitive abilities needed for creativity</li> </ul>
Creative Problem Solving	All Levels	No special materials. Makes great use of Brainstorming	<ul style="list-style-type: none"> <li>• Finding problems</li> <li>• Collecting data</li> <li>• Finding ideas</li> <li>• Finding solutions</li> <li>• Implementing solutions</li> </ul>
Talents Unlimited	All Levels	Workbooks based on idea of 'inventive thinking', aimed at problem solving Emphasis on Brainstorming	<ul style="list-style-type: none"> <li>• Thinking productively</li> <li>• Communicating</li> <li>• Planning</li> <li>• Making decisions</li> <li>• Forecasting</li> </ul>
Khatena Training Method	Adults and Children	No special materials— Simple teacher-made aids	<ul style="list-style-type: none"> <li>• Breaking away from the obvious</li> <li>• Transposing ideas</li> <li>• Seeing analogies</li> <li>• Restructing information</li> <li>• Synthesizing ideas</li> </ul>
Osborne-Parnes Program	High School and College Level	No special materials Primary emphasis on Brainstorming,	<ul style="list-style-type: none"> <li>• Getting many ideas</li> <li>• Separating idea generation and idea evaluation</li> </ul>
Clapham-Schuster Program	College Level	No special materials Relaxation exercises Definition of creativity as involving combining ideas Brainstorming, Synectics, etc	<ul style="list-style-type: none"> <li>• Getting ideas</li> <li>• Understanding creativity</li> <li>• Using metacognitive techniques (setting goals, expecting success, coping with failure)</li> </ul>

with causal relationships; making unjustified sweeping generalizations that are either not unequivocally supported by research or are even contradicted by some findings; drawing unwarranted conclusions about the implications of research findings for practice; failing to understand the factors that inhibit conversion of admirable recommendations into practice. Some popular books proclaim incompletely digested research findings as containing a 'revolutionary' panacea that can be applied in a set way in any and all situations, without taking account of the individuals involved, the special characteristics of the situation, or the personal or structural factors facilitating or impeding imple-

mentation of good practice. We recommend moderation, flexibility and sensitivity in their use.

#### *The Need for a Holistic Approach to Fostering Creativity*

From almost the beginning, doubts have been expressed about whether procedures for fostering creativity really achieve what they set out to do (e.g. Mansfield, Busse & Krepelka, 1978). Wallach (1985) showed that effects are very specific. Treffinger, Sortore and Cross came to the conclusion that it has not been shown that there are clearly-definable effects of

creativity training on specific cognitive or personal characteristics, for instance that particular programs foster specific aspects of children’s psychological development, or that children with one particular psychological profile benefit from a specific program, whereas other children need a different one.

Although later programs include knowledge, problem solving and decision making (Treffinger, Sortore & Cross, 1993), Cropley (1997a) argued that they still concentrate overwhelmingly on the cognitive aspects of creativity, even if factors such as self-concept or positive attitudes to problem solving are sometimes considered (see Table 1). He criticized the narrowness in the conceptualization of creativity inherent in the programs, and called for an integrative, holistic approach, as also did Urban (e.g. 1997).

Treffinger, Sortore & Cross also stressed the importance of what they called the “full ‘ecological system’ of creativity” (1993, p. 560). This involves recognition of creativity’s interaction with other psychological properties of the individual, aspects of the creative process, effects of the situation, characteristics of the task itself, and the nature of the desired product. They concluded that it is possible to foster creativity in this ‘ecological’ or ‘interactionist’ sense, but that the factors just mentioned must be specified.

Cropley (1999b) called for ‘differential diagnosis’ of creativity, and suggested that the different kinds of creativity tests that are now emerging could provide the tools for this. Table 2 shows the theoretically possible combinations of knowledge, thinking, motivation and personal properties. A plus sign indicates a favorable state for creativity, a minus sign an unfavorable one.

Column 1 depicts a child in whom all four elements are favorably developed, and represents ‘fully realized’ creativity, Column 2 describes a child in whom the personal properties are unfavorable (‘stifled’ creativity), Column 3 a child in whom motivation is missing (‘abandoned’ creativity), and Column 4 a child without the necessary thinking skills (‘frustrated’ creativity). Children with different combinations of psychological prerequisites would require different emphases in procedures to nurture their creativity: For example, where only motivation is lacking (Column 3), a different approach would be needed in comparison with a child who was highly motivated but lacking in openness, flexibility and self-confidence (Column 2).

In order to base programs on the full ecological system of creativity, it will be necessary to specify: (a) the factors that are involved in the development of children’s capacity to be creative (for instance, abilities, motivation, personal properties, and positive social conditions); (b) the nature of the interactions among these factors; (c) the nature of the creative process. The analysis of the process needs to be capable of integrating research findings showing the simultaneous importance of conflicting factors such as divergent and convergent thinking, intrinsic and extrinsic motivation, or apparently contradictory personality characteristics. An appropriate model is presented below.

**A Comprehensive Theoretical Framework for Fostering Creativity**

*The Componential Model of Creativity*

Urban’s (1990) components model specifies the relationships among characteristics of the learner and the setting. It is based on six components, each with a set of subcomponents that work together for and in the creative process, within a framework of environmental conditions (see Fig. 1). The first three components, which are cognitive in nature, are:

- (1) Divergent thinking and acting
- (2) General knowledge and a thinking base
- (3) A specific knowledge base and area specific skills.

The other three components, representing personality, are:

- (4) Focusing and task commitment
- (5) Motivation and motives
- (6) Openness and tolerance of ambiguity.

The model (for more detail see Urban, 1990, 1994, 1995a, 1997) emphasizes that the elements of creativity form an interacting, mutually dependent system. A simple example is that divergent, associational thinking is linked with deep domain-specific knowledge, broad, open perception, and networking in the processing and storing of information. Other related subcomponents are the resistance to group pressure that is necessary for non-conformist behavior and autonomy of thinking, at least at certain times and in certain settings (such as the classroom). Readiness to take risks permits remote

Table 2. Possible combinations of psychological prerequisites for creativity..

	Possible Combinations															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Knowledge	+	+	+	+	-	-	-	-	+	+	+	+	-	-	-	-
Thinking Skills	+	+	+	-	+	+	-	-	-	-	-	+	+	+	-	-
Motivation	+	+	-	+	+	-	+	-	-	+	-	-	+	-	+	-
Personal Properties	+	-	+	+	+	+	+	+	-	-	+	-	-	-	-	-

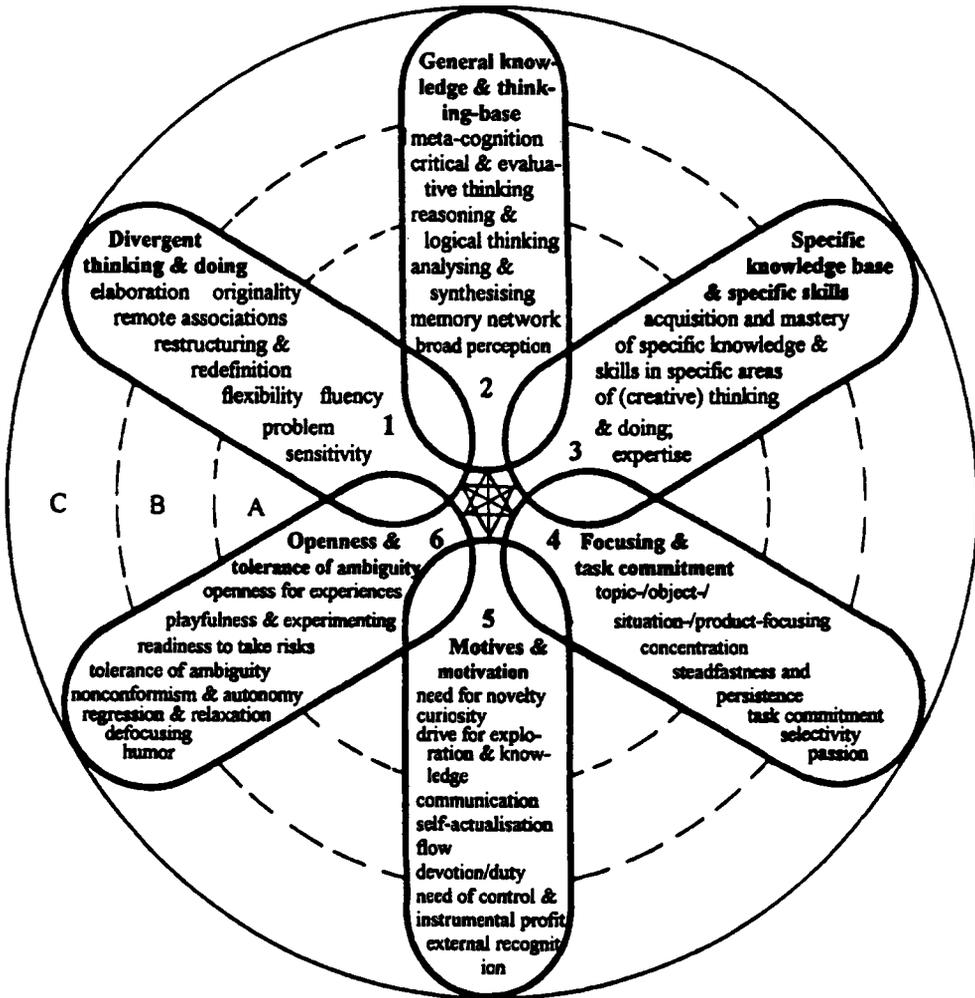

Figure 1. The componential model of creativity.

associations, playfulness and willingness to experiment go with fluency and flexibility, and tolerance of ambiguity is supported by passion.

No single component alone is sufficient or responsible for the whole creative process leading to a creative product. The (sub)components are used for, participate in, or determine the creative process to differing degrees, and work with differing subcomponents or combinations of subcomponents. Each (sub)component plays its interdependent, functionally adequate role at a certain stage or phase of the creative process, a certain level, or in a certain situation. Each component is a prerequisite for and at the same time a result of others.

The dynamics and mechanics of the componential functional system are dependent on the discouraging/inhibiting versus nurturing/stimulating/inspiring/cultivating influences of the various environmental systems in which creative individuals become active. These may be classified in a threefold way:

- (1) The individual, subjective dimension, with the direct, situational, material, and social environment.
- (2) The group or local dimension with family, peer group, school, local educational system (the micro-environment).

- (3) The societal, historical, global dimension with the cultural, political, and scientific conditions (the macro- and meta-environment).

### *The Stage Model of Creativity*

Cropley (1997a) focused attention on the process of creativity, emphasizing especially its 'paradoxical' nature (Cropley, 1997b). Taking Wallas's (1926) phase model as a starting point, he expanded it by adding to Wallas's phases ('Information', 'Incubation', 'Illumination', 'Verification') further stages of 'Preparation', 'Communication' and 'Validation' (see Table 3). Preparation makes the stage of problem finding more explicit. Communication and Validation are necessary because without them novelty may be produced, but cannot receive 'sociocultural validation'.

In each stage (see left hand column), psychological processes (second column) produce a psychological 'configuration' (Simonton, 1988) shown in the third column, that forms the material for the next stage. The psychological processes are made possible or at least facilitated by motivational states (fourth column) and personality characteristics (fifth column). Table 3 depicts a process culminating in a socially-validated product. The process can, however, be broken off earlier, for instance when executive or metacognitive

processes indicate that the current configuration is doomed to failure. The creative process can also start part way through, for instance when a person who has in the meantime learned more returns to a configuration previously abandoned, thus restarting the process.

Dividing the emergence of effective novelty into stages, as in Table 3, aids understanding of paradoxical aspects of creativity. For instance, in the stage of information, convergent thinking, naiveté, and intrinsic motivation might be of paramount importance, whereas in the stage of illumination, divergent thinking, general knowledge and openness might predominate, or in that of verification, toughness, courage, extrinsic motivation, specific knowledge and convergent thinking. Rather than pursuing a vague, global goal of 'fostering creativity', teachers need to be aware of which aspects of creativity they wish to promote, and which particular activity is likely to do this, while students need to understand in a more specific and concrete way the precise purpose of what they are learning. The extended phase model offers a framework for doing this.

### **Fostering Creativity in the Classroom**

Teachers need to review their own practices in order to evaluate how far their teaching is suited to fostering

*Table 3. The emergence of a creative product.*

Stage	Process	Result	Motivation	Personality
Preparation	identifying problem setting goals convergent thinking	initial activity general knowledge special knowledge	problem-solving drive (intrinsic) hope of gain (extrinsic)	critical attitude optimism
Information	perceiving learning remembering convergent thinking	focused special knowledge rich supply of cognitive elements	curiosity preference for complexity willingness to work hard hope of gain	knowledgeability willingness to judge and select
Incubation	divergent thinking making associations bisociating building networks	configurations	freedom from constraints tolerance for ambiguity	relaxedness acceptance of fantasy nonconformity adventurousness
Illumination	recognizing a promising new configuration	novel configuration	intuition reduction of tension	sensitivity openness flexibility
Verification	checking relevance and effectiveness of novel configuration	appropriate solution displaying relevance and effectiveness	desire for closure desire to achieve quality	hardnosed sense of reality self-criticism
Communication	achieving closure gaining feedback	workable product capable of being made known to others	desire for recognition (intrinsic) desire for acclaim or reward (extrinsic)	self-confidence autonomy courage of one's convictions
Validation	judging relevance and effectiveness	product acclaimed by relevant judges (e.g. teacher)	desire for acclaim mastery drive	toughness flexibility

development of children's creative thinking, learning, and acting. In this section we provide guidelines they can refer to in order to become 'creativity fostering' teachers.

#### *A Framework for Stocktaking*

Creativity is not simply a matter of helping children get better at having as many ideas as possible in the shortest possible time. On the contrary, it involves both the whole person and all aspects of personal development as well as all phases of the creative process. The questions below are based on the components model, and provide a framework for teachers to evaluate their own classroom practices. They refer to classroom instruction at all levels.

#### Component 1: Divergent thinking

- Is asking questions allowed and appreciated?
- Is the teacher open and sensitive to problems raised by students?
- Does the teacher try to make children aware of open questions, sensitive to their environment, and willing to use all their senses?
- Are problems simply presented, or (to the maximum degree possible) discovered? Are preexisting answers simply presented?
- Do time and organisation allow more than one attempt at finding a solution?
- Are objects and topics considered from different aspects?
- Are phases or ways and/or goals/products kept open or shaped openly?
- Are students encouraged not always to be satisfied with the first correct solution?
- Is a 'deviant' method or solution—originality—expected and appreciated?
- In general, does anything happen (in school) that could be called 'divergent thinking'?

Or is learning nothing more than regurgitation of accumulated knowledge that has been obtained from textbooks or teachers?

#### Component 2: General knowledge and thinking base

- Do learning tasks require and promote broad and differentiated perception, or do they restrict focus?
- Does learning use different sensory channels and varying methods, so that experiences and knowledge may be anchored and accessible in memory storage in various ways?
- Is the structure of learning objects/subjects analysed?
- Is there a focus on the learning process, not simply on the result?
- Are solution methods questioned or optimized?
- Are 'why?' questions asked and answered, so that cause-effect relations can be studied?

- Is there instruction on systematic analysing and synthesising of problems, topics, facts, situations etc.?
- Are there challenges requiring both inductive and deductive reasoning?
- Is evaluation asked for and desired?
- Is the learning process made explicit and reflected upon with students, so that metacognitive thinking is initiated and furthered?

#### Component 3: Specific knowledge base and specific skills

- Is the development of special interests encouraged? For example, by additive or extracurricular provision, mentor systems, competitions, etc.?
- Are individual interests brought into or built into school work?
- Are there opportunities/possibilities for students to obtain experience via in-depth studies?
- Is both experts' and children's expertise appreciated?

#### Component 4: Focusing and task commitment

- Is sustained occupation with a special activity allowed or supported (for example, research work on a project carried on for the entire school year)?
- Do the timetable and school organisation support such activities?
- Is task commitment rewarded?
- Is there an expectation that tasks have to be fulfilled and brought to an end?
- Are children supported in recognizing and avoiding distractions?
- What is the role of self-evaluation and external reward?

#### Component 5: Motives and motivation

- Are children's questions accepted and expanded upon?
- Is the curiosity of the children stimulated and supported?
- Are there opportunities for self-directed learning and discovery learning, in order to support and promote intrinsic motivation?
- Are individual interests appreciated and supported?
- Is unnecessary repetition avoided?
- Can children identify with their work?

#### Component 6: Openness and tolerance of ambiguity

- Is school not only a place for traditional instruction, but a place of living, of fun, of (mental) adventure?
- Does instruction bring the real world into school, does instruction reach out into reality?
- Is school a place for fantasy and imagination?
- Is school a place for eu-stress and relaxation?
- Is there a place for laughter (not at the expense of others) and appreciation of humor?

- Is the teacher able to accept an open result for an instructional unit?
- Are there opportunities to explore and investigate objects in a playful and experimental way?
- Are errors allowed, or are quick and correct results demanded?
- Is the individuality and uniqueness of each person appreciated, or is conformist behavior demanded?

### Introducing 'Open Learning'

The pedagogical concept of *open teaching and learning* seems to provide essential conditions for fostering creativity and giftedness (Urban, 1995b, 1996). When adopted by highly competent teachers, open learning and instruction mean:

- offering meaningful enrichment of the children's perceptual horizons;
- enabling self-directed work, allowing a high degree of initiative, spontaneity, and experimentation without fear of sanctions against incorrect solutions, errors, or mistakes;
- encouraging and accepting non-conformist behavior and the adaptation of original ideas;
- providing for challenging and stimulating learning materials;
- creating organisational and structural conditions that allow open and reversible distribution of roles, themes, and problems, as well as sharing of activities;
- providing support and positive feedback for questioning and exploring behavior and problem finding, and not just problem solving;
- fostering identification of the child with school (learning) activities by allowing self-determination and joint responsibility;
- supporting development of positive self-assessment and a favourable self-concept;
- increasing autonomy in/of learning by recognition and self-evaluation of progress;
- making it possible for children to experience social creativity and the 'creative plus' during group interactions and through joint projects with self-selected partners;
- reducing stress on achievement and avoiding negative stress by introducing playful activities;
- fostering intense concentration and task commitment through high motivation and interest in self-selected topics;
- creating an atmosphere free from anxiety and time pressure;
- establishing psych(olog)ical security, openness, and freedom;
- nurturing sensibility, flexibility, and divergent thinking.

This kind of concept implies a changed and enriched role of the educator or teacher, who is no longer just instructor, evaluator, censor, and authority, but stim-

ulator, elicitor, moderator, stabiliser, helper, mediator, counsellor, friend, participating observer, initiator, partner, instructor, organiser, expert, mentor, and model (Urban, 1996).

### Recommendations for Stimulating and Nurturing Creativity in School

These recommendations, though formulated for teachers in school, are in principle also true for other educational institutions, as well as settings such as the workplace, where there is a felt need for creative productivity or innovation.

- (1) Stimulate and maintain a creative group atmosphere, which allows learners to speak, think, and work free of stress and anxiety and without fear of sanctions.
- (2) Avoid group pressure and factors such as envy associated with competition, but allow and support a cooperative climate.
- (3) Try to avoid and prevent negative reactions or sanctions by classmates.
- (4) Provide for adequate alternation of periods of activity and relaxation that foster musing.
- (5) Demonstrate and appreciate humor.
- (6) Stimulate and support free play and manipulation of objects and ideas (e.g. 'What if . . .?').
- (7) Support self-initiated questioning and learning.
- (8) Provoke and provide for situations challenging, stimulating, requiring creative behavior.
- (9) Be careful with/hold back (excessively) rapid feedback promoting (rigid) patterns of behavior or solutions.
- (10) Act as a model for and support questioning of rules or seemingly indispensable facts or patterns.
- (11) Try to avoid 'suggestive' questions or questions that require a simple 'yes/no' answer, as much as possible.
- (12) Instead of questions try to formulate statements that may stimulate or provoke questions by the students.
- (13) Do not provide strategies for finding solutions too quickly, but give hints step-by-step in order to stimulate independent thinking.
- (14) Allow errors and mistakes (as long as they are not physically or psychologically harmful to the child or to others).
- (15) Interpret errors as signs of individual and constructive effort towards a self-detected solution.
- (16) Try to discover the 'other' or deviant or poor or incorrect strategy that led to an error (qualitative error analysis).
- (17) Try to make students sensitive to stimuli from different aspects of the environment (material, symbolic, social).
- (18) Support interest in and acquisition of knowledge in a broad variety of different areas.

- (19) Give stimulation and examples for systematic investigating, redefining, altering of ideas, stories, statements, presentations, etc.
- (20) Demonstrate tolerance and appreciation of unusual thoughts, original ideas, or creative products.
- (21) Teach students, to accept, acknowledge, and appreciate their own creative thinking, behavior and production as well as that of others.
- (22) Provide for manifold and stimulating material for the elaboration of ideas.
- (23) Support and attach importance to the full elaboration or realisation (of all implications) of creative ideas.
- (24) Develop and demonstrate constructive criticism, not just criticism.
- (25) Make students sensitive to possible implications and consequences of solutions.

Some idea of what these processes would mean in everyday practice can be gained from the following examples. Information could be drawn from students' experiences outside school, for instance during camping trips, out-of-school projects, hobby activities, or even shopping (Introducing Open Learning, first point: "Offering meaningful enrichment of the child's perceptual horizon"). The teacher could also go beyond setting tests on which answers can be scored either 'correct' or 'incorrect', and include at least some open items, or even items that are insoluble. Students could be required to describe the thinking that led to the best answer they could find to such questions, and grades could be based on the nature of this reasoning, regardless of formal correctness (or not) of the actual answer (Framework for Stocktaking, Component 2, fourth point: "Is there a focus on the learning process and not simply the result?"). In a history lesson, for instance, instead of asking for a list of the causes of the American War of Independence a teacher could ask students to describe what the modern world would be like if the British had granted the North American colonies representation in the House of Commons (Recommendations for Stimulating and Nurturing Creativity, Number 6: "Stimulate and support free play and manipulation of objects and ideas").

Fostering creativity is an integral part of education, and should be a guiding principle for teaching all children. In the case of the gifted, however, it takes on special importance, because it permits 'true' giftedness. However, fostering creativity should not be reduced to a collection of set exercises carried out at fixed times as part of a 'creativity program'. The desire to foster it is at the heart of a philosophy or principle that should underlie all teaching and learning, in all subject areas and at all times.

# Developing Gifted Programs

Sidney M. Moon<sup>1</sup> and Hilda C. Rosselli<sup>2</sup>

## Introduction

The word 'program' has been used in many ways in the field of gifted and talented education. At a *macro level*, a national or regional ministry of education might specify parameters for gifted education for an entire country and call that a gifted program. For example, Israel's ministry of education established a Department of Gifted Children and Science Oriented Youth to be responsible for the gifted education program in Israel (Burg, 1992) and the gifted education program in Singapore was initiated, planned, and implemented by the Singapore ministry of education (Goh, 1994). Similarly, Siberia developed a large-scale regional project to develop science talent that involved selecting talented high school seniors for accelerated university education, engagement in research, and postgraduate work at research institutes (Masharov, 1993).

At the *local level*, there are numerous examples of local school districts developing gifted programs to fit a specific local context (see for example Powley & Moon, 1993; Whitman & Moon, 1993; Nidiffer & Moon, 1994). In between these extremes are programs developed to serve an entire city such as CEDET, a comprehensive, individualized, enrichment program for Brazilian students in grades 1–8 (Guenther, 1995). What all of these efforts have in common is an articulated set of services for an identified subpopulation of gifted and talented students in a specific location or region. These services include identification procedures and differentiated educational experiences in a specified delivery format and are designed to develop the talents of high ability youth.

Theoretical models for gifted programs also range from the general to the specific. At the general level, a model such as the Purdue Secondary Model (Feldhusen & Robinson, 1986) provides a generic framework for comprehensive programming for gifted and talented students at the secondary level. Other general models provide templates for the development of specific

program components in specific contexts, but are not really programs themselves. The Purdue Three-Stage Model (Feldhusen & Kolloff, 1986; Moon, 1993; Moon, Feldhusen, Powley, Nidiffer & Whitman, 1993) and the Kaplan grid model (Kaplan, 1986) are examples. Both of these models provide frameworks for program and curriculum design that can be applied in a wide variety of contexts. At the specific level, a model such as the Program for Academic and Creative Enrichment (PACE) (Kolloff & Feldhusen, 1981) specifies the identification procedures, format, and curriculum for a two-hour/week pullout enrichment program for children aged 9–11. In between, models such as the Schoolwide Enrichment (Renzulli & Reis, 1985) and the Autonomous Learner (Betts, 1985) specify in great detail the design parameters of enrichment programs with integrated, embedded program components. Theoretical program models provide guidance for the development of gifted and talented programs but are not themselves programs unless they are implemented in a specific local context.

This chapter focuses on the *process* of developing programs for gifted and talented students, rather than on specific program models. As used here, a *program* is an educational experience that is planned and implemented in a specific location or region for the purpose of enhancing the development of identified gifted and talented students. The chapter provides guidance for persons charged with developing programs for gifted and talented students by: (a) discussing theoretical, cultural, and political issues that influence the program development process; (b) outlining strategies that are helpful in planning and designing gifted programs. Throughout, the emphasis is on *situated program development*, i.e. program development that is designed to fit a specific local context.

## Contextual Issues

### *Theoretical*

Before one develops a program for high ability students, it is helpful to spend time clarifying the theoretical basis of program development efforts.

<sup>2</sup> University of South Florida, Tampa, Florida, USA.

Program developers should be aware of the conceptual foundations of the field, competing theories of giftedness, and differing viewpoints on key issues in gifted education. Ambrose (1998) has proposed a hierarchical model of the conceptual foundations of gifted education that includes world views (e.g. mechanism, contextualism, organicism, and formism); disciplinary perspectives (e.g. the 'hard' vs. the 'soft' sciences), and levels of operation (e.g. theory, research, and practice). This model can be used by program developers to organize the various theoretical perspectives in the literature and prevent the polarization that can result when different individuals hold different world views or come from different disciplinary specializations. Using Ambrose's (1998) framework either/or thinking can be replaced by a broader more divergent consideration of many ideas and potential integrative connections. Ideally, this integrative process will occur when stakeholders work together to develop a shared philosophy of gifted education at the beginning of program development efforts.

#### Conceptions of Giftedness

One of the most important conceptual foundations of a gifted program is the theory of giftedness that undergirds the program. Theories of giftedness influence all aspects of program development including program philosophy and goals, identification procedures, program delivery format, and instructional strategies. On a less tangible level, conceptions of giftedness influence perceptions of the need for specialized programming, the cast of stakeholders who will play a pivotal role in the development of the program, and the level and type of advocacy necessary to support program efforts. Numerous conceptions of giftedness have been proposed by scholars in the fields of psychology and education (Sternberg & Davidson, 1986). Although some believe the field of gifted education needs a unifying conception of giftedness (Gagne, 1999), others feel a plethora of competing conceptions is both necessary and valuable (Borland, 1999).

Existing conceptions of giftedness have been categorized in different ways. For example, Sternberg (1986), has categorized conceptions of giftedness into implicit vs. explicit theories. *Implicit theories* are definitions that lie within the heads of the theorists whether those 'theorists' are experts or lay persons. Such theories cannot be empirically tested. It is important for program developers to be aware of the implicit theories of giftedness held by various program stakeholders, particularly if these implicit theories differ from the conception of giftedness that the program developers are using as a foundation for program development efforts. *Explicit theories* are testable theories that assume specific definitions and seek to relate those definitions to other constructs through empirical research. Often the assumptions underlying the definitions of giftedness used in research studies have not

been critically examined by the researchers. Program developers also need to be discerning about the assumptions about giftedness underlying much of the empirical research literature in order to interpret that literature effectively in a specific context.

Conceptions of giftedness are influenced by definitions of the constructs that underlie them as well as by the hypothesized relationships between those constructs. At the close of the 20th Century, there is little consensus among scholars in the fields of psychology and education about such constructs as *intelligence* (Gardner, 1983; Sternberg, 1985, 1986, 1996; Neisser et al., 1996), *creativity* (Glover, Ronning & Reynolds, 1989; Runco & Albert, 1990; Sternberg, 1999), *motivation* (Pintrich & Schunk, 1996; Clinkenbeard, 1997), *expertise* (Ericsson, Krampe & Tesch-Romer, 1993; Ericsson, 1996; Sternberg & Horvath, 1998), *levels of ability* (Gagne, 1998), and *gifts and talents* (Feldhusen, 1998; Gagne, 1999). There is also little consensus about the relationships among these constructs in the development of giftedness (Renzulli, 1986b; Stanley, 1997; Feldhusen, 1998).

A recent, striking example of the controversy surrounding these core constructs was stimulated by Gagne's (1999) treatise on his beliefs about abilities, gifts, and talents. Gagne distinguished between natural abilities (giftedness) and abilities that have been systematically developed through a structured program of learning, development, and practice (talents). Gagne's essay garnered an interesting array of responses that ranged from viewing exceptional human ability as a regression equation consisting of general intelligence, domain-specific skills, and practice (Detterman & Ruthsatz, 1999) to a reaffirmation of the distinction between gifts as general, system-wide capabilities and talents as specific, within-domain capabilities (Feldman, 1999). Given this diversity of viewpoints, it is helpful if some members of a program development team can familiarize themselves with the literature on conceptions of giftedness prior to beginning program development efforts. Ideally, program developers should receive training in the field of gifted education and/or talent development psychology. If extended training and/or independent study is not possible, consultants can be hired to help develop a coherent theoretical foundation for program development efforts.

#### Critical appraisals of gifted education

Even if the debate regarding conceptions of giftedness were to be resolved, there would still be a need for ongoing critical reflection about the fundamental premises and practices of the field of gifted education. Gifted education has been shaped through advocacy, but advocacy without self-examination can border on fanaticism (Borland, 1996). Thus, this chapter would be incomplete without mentioning some of the critiques of gifted education. Seldom has there been as

cogent a collection of critical appraisals of the field as the one compiled by Lawrence Coleman in the Winter 1996 issue of the *Journal for the Education of the Gifted*. This issue provided a powerful array of essays from both proponents and opponents of the field. Readers were roused to question the field's reluctance to ask of ourselves the questions asked by critics of gifted education (Borland, 1996), to recognize impressive accomplishments of the field as well as areas still worthy of scrutiny (Callahan, 1996), and to consider talent development as a new conceptual framework that extends and redefines the nature of giftedness, identification, and programming (Treffinger & Feldhusen, 1996). Margolin (1996) argued that gifted education is really a strategy to develop a class of people who lead and direct others, and, thus, a pedagogy of the oppressed. In a similar vein, Sapon-Shevin (1996) argued that gifted education is a form of 'educational triage' in that programs are created for those for whom educational failure would be unacceptable. The result is a continued focus on improving education for the privileged rather than considering a comprehensive overhaul of the entire educational system. Sapon-Shevin also reminded us that when we define "what gifted students need," we are using a blanket approach that may fail to recognize the unique educational needs of particular gifted students. Gallagher (1996) noted that many of the criticisms raised in the special issue were really questions of ethics and philosophy.

This collection of essays, along with other critical appraisals of the field of gifted education, can help program developers clarify their values and viewpoints. Program development teams would benefit from reading such critiques in a reflective mode, using their context as the backdrop for spirited discussion of these critical appraisals of gifted education and their relevance to local program development efforts.

### *Cultural*

Cultural influences on gifted and talented programs are often quite marked (Robinson, 1992b). These influences stem from beliefs and values. Many cultures have deeply ingrained beliefs about concepts such as the nature of giftedness and the purpose of education. These beliefs can have a strong influence on educational policies for gifted and talented students (Freeman, 1992), as can cultural values (Braggert, 1993; Taylor, 1993; Stevenson, 1998).

### *Beliefs*

Socio-cultural influences often shape the implicit conceptions of giftedness that evolve in particular settings. Historically, many cultures believed that human talents were an endowment of the gods (Hunsaker, 1995). For example, in the ancient greco-Roman culture special intellectual and artistic abilities were believed to come from the Muses. In modern

times, belief in divine dispensation is less prevalent. Instead, modern cultures tend to believe that unusual abilities are the result of heredity, environment, individual effort, or some combination of these. Which of the three receives the greatest emphasis in a particular culture can have a dramatic impact on gifted education.

In the United States and Canada, a prevailing cultural belief is that individual differences in abilities are largely the result of natural endowments. For example, the province of Saskatchewan in Canada defines giftedness as "superior natural ability or exceptional talent" (Goguen, 1993). This belief in natural gifts leads to an educational focus on measuring individual differences and providing educational programming that is an appropriate match for an individual's measured abilities (Tannenbaum, 1986; VanTassel-Baska, 1998b). In most Asian countries, on the other hand, the prevailing cultural belief is that individual differences in abilities are largely the result of effort (Stevenson, 1994, 1998). Hence the emphasis in Asian education is on teacher skill and pupil diligence.

Some cultures foster a unified belief system about the nature of giftedness. Others encourage a variety of competing beliefs in an open marketplace of ideas. Where a single belief system holds sway it is very difficult to implement gifted and talented programming that flows from another conception of giftedness. For example, Nowicka (1995) cited denial of the existence of genetic differences during the communist period as a historical barrier to the development of gifted education in Poland.

The United States (Gallagher, 1993), Canada (Goguen, 1993), and Western Europe (Urban & Sekowski, 1993) are examples of cultures which foster competing conceptions of giftedness. In these cultures, the prevailing conception of giftedness in a given locality tends to be determined by political processes rather than by cultural ones. Hence many types of gifted programming are found in these countries and beliefs about the nature of giftedness tend to be seen as values held by certain groups of people rather than as shared beliefs about the 'Truth'.

*The Purpose of Education.* Cultures also differ dramatically in their beliefs about the purpose of education, especially for talented individuals. Some cultures emphasize education as a means to individual development while others believe education is a means of achieving collective or national goals. Often cultural beliefs about the purpose of education will change over time. For example, traditional African societies viewed the purpose of education to be establishing a favorable environment for the development of special abilities; children who demonstrated special abilities were viewed as needing specialized education to prepare them for their adult roles as priests, herbalists, etc.

(Hunsaker, 1995). Taylor (1993), however, suggests that modern African societies believe that the purpose of education is to enhance togetherness and communal responsibility rather than to promote individual development; as a result, African nations today tend to place greater priority on educating the majority and disadvantaged students than on educating students with special talents.

Israel is an example of a modern culture that believes the purpose of education is multi-faceted: encouraging the pursuit of individual excellence, as well as enhancing the ability of young people to contribute to society (Burg, 1992; Passow, 1994). Perhaps as a result, Israel has a well-developed national policy of gifted education that encourages a wide variety of types of gifted and talented programming including special schools, special classes, and enrichment schools (Burg, 1992).

Both China and Korea have been heavily influenced by Confucianism (Robinson, 1992b; Oh-Hwang, 1993). Confucianism holds that success is equivalent to wealth and prestige and is attained primarily through education. Hence cultures influenced by Confucianism believe that education is important for success in life and have a long tradition of promoting achievement and talent on the basis of examinations. Since higher education is a scarce resource in these countries, much of the focus of pre-college education is on achieving a high enough score on national college entrance examinations for selective college entrance (Robinson, 1992b; Oh-Hwang, 1993). This narrow focus on academic achievement as measured by competitive examinations makes it very difficult to develop gifted and talented programs for any other purpose than improving examination scores (Hsueh, 1998).

Under communist leadership, Eastern European countries, the USSR, and China, banned the study and testing of individual differences but promoted the development of individuals with unusual potential in sports, science, and the arts because such individuals could enhance national honor by winning international competitions (Urban & Sekowski, 1993; Stevenson, 1998). Hence beliefs about talent development in communist countries were bifurcated: one set of beliefs governed normal education for most students and another governed the education of extremely talented individuals in domains where excellent performance could bring national prestige. These bifurcated beliefs appear to have been largely political in nature, rather than truly cultural. In most of these countries, these beliefs are being replaced by beliefs that are more consistent with underlying cultural traditions i.e. eastern Europe is aligning itself with the beliefs of democratic countries (Urban & Sekowski, 1993) and mainland China is aligning itself with the traditional beliefs of Confucianism (Robinson, 1992b).

Some cultures believe that the primary purpose of education, especially in the pre-high school/college

years, is the reduction of individual differences, e.g. Japan (Stevenson, 1998), while others believe that education should help even very young children differentiate, e.g. England, Germany, and Holland (Urban & Sekowski, 1993). When beliefs are deeply rooted, shared by most individuals in a nation or region they can have a strong influence on gifted education. For example, most people in the Scandinavian countries hold egalitarian beliefs about the purpose of education; as a result these countries tend to be opposed to special provisions for gifted students (Freeman, 1992; Urban & Sekowski, 1993; Persson, 1998).

### Values

*Family values.* Differences in family values can affect program development efforts. In cultures where filial piety is a strongly held value, and parents exercise considerable control over their children's lives, parental pressures may heavily influence gifted and talented programming. For example, in Taiwan parents value good grades and high scores on exams to the exclusion of other aspects of talent development (Hsueh, 1998). As a result it is very difficult to get parental support for programs to develop humanistic or artistic talents in Taiwan. Similarly, in Korea parents are the absolute authority and value conformity so it is difficult to develop programs to nurture creativity or flexible, creative learning environments (Oh-Hwang, 1993). In some subcultures in the United States, such as the African American, families may view gifted programs as threatening to their family and cultural values and so may not be supportive of their children's participation in such programs (Exum, 1983).

*Conformity vs. independence.* One of the ways the values of cultures differ is with respect to the conformity-independence continuum (Sisk, 1990). Cultures like the American and Western European that value individualism and independent thinking tend to be supportive of many different types of gifted and talented programming, while cultures that value conformity tend to be supportive of a narrower range of programs. For example, programs that focus on the development of creative talents are common in the United States (see for example, Kolloff & Feldhusen, 1981; Renzulli & Reis, 1985) and Brazil (see for example, CDET, Guenther, 1995), two countries that value independent thinking, but rare in Japan (Stevenson, 1998) and Korea (Oh-Hwang, 1993), countries that value conformity and obedience.

Cultures also differ in the amount of conformity that is expected with respect to curriculum and pedagogy. In countries where educational policy and curriculum are established at the national level, local efforts to develop gifted and talented programming are not likely to be successful unless they occur in the private sector (Urban & Sekowski, 1993; Wu & Cho, 1993). If

broadly-based gifted education is to occur in these countries, a mandate for it must become integrated into national policy. In countries with decentralized educational systems, on the other hand, regional and/or local program development may be strongly encouraged (Gallagher, 1994; Passow & Rudnitski, 1994; Robinson, 1999).

*Differential Weighting of Talent domains.* Cultural values can also influence levels of support for talent development in specific domains. In some regions such as Western Europe (Freeman, 1992; Tirri & Uusikyla, 1994), Taiwan (Hsueh, 1998), and Korea (Oh-Hwang, 1993), a traditional emphasis in the educational system on academic subjects makes it difficult to develop programs to nurture creativity or non-traditional talents. Exactly the opposite pattern can prevail in egalitarian countries such as Finland (Tirri & Uusikyla, 1994), where special classes may be supported for children gifted in music and sports but not for the intellectually gifted.

In Africa, cultural values include community and togetherness and the importance of affective and social development. As a result, the African culture values social giftedness more than academic or technological giftedness (Taylor, 1993). African nations are likely to be more supportive of gifted education if an emphasis is placed on the social/emotional domain in addition to academics or if programming focuses on developing social/emotional talent. Another country that emphasizes social goals for gifted education is Singapore (Goh, 1993) where gifted education is viewed "as benefiting society as a whole, not just the individual" (Goh, 1994, p. 52). Similarly, Israel's residential high school for the arts and sciences was motivated by the belief that Israel must "encourage her youth to achieve excellence, not only in their areas of talent potential, but excellence as human beings by nurturing deep moral, social, and civic commitment" (Passow, 1994, p. 54). A desired outcome of gifted education in both countries is talented adults who have a strong commitment to their society.

National goals can also influence levels of support for different talent domains. In Eastern Europe under the communists, special schools were established to develop the most talented pupils for international competitions in sports, art, music, and science, but no individualization or differentiation was provided in academic subjects at regular schools or for individuals with more moderate levels of talent in sports, art, music, and science (Urban & Sekowski, 1993). China has supported gifted education in part because it has been seen as promoting the need of their society for modernization; similarly, one of the reasons Taiwan supports gifted education is the belief that an island economy with scarce national resources needs to develop its human resources (Stevenson, 1994). The

talent domains supported by national welfare rationales are usually science and technology.

*Philosophies of education.* Perhaps the most important cultural influences on gifted education are those related to educational philosophies (Freeman, 1992; Wu & Cho, 1993; Stevenson, 1998). The *egalitarian* philosophy holds that the primary purpose of education is to create similar outcomes for all students (Freeman, 1992; Robinson, 1992a; Persson, 1998). Thus an important educational goal in an egalitarian culture is the reduction of individual differences. In contrast, an *equal opportunity* culture values equality of opportunity more than equality of outcomes and recognizes that providing equal opportunities may actually increase the differences between individuals (Gallagher, 1993; Urban & Sekowski, 1993). A core educational value in an equal opportunity culture is adapting instruction to meet individual needs. In an egalitarian culture, achieving excellence beyond age-group norms is discouraged. In an equal opportunity culture, achieving excellence beyond age-group norms is encouraged to the extent that resources are available.

Both types of cultures emphasize educational equity but they do so in different ways. In the egalitarian culture, equity is achieved by making sure that all students experience exactly the same educational experiences regardless of their individual differences. A common educational experience is provided and similar outcomes are expected for all students. For example, in the Sweden (Persson, 1998), Poland during the communist regime (Ekiert-Grabowska, 1994), and Japan (Stevenson, 1994; Stevenson, 1998), one rationale for providing a uniform curriculum to all children in the elementary grades has been equity—all children are perceived as being given equal chances to learn because they all experience the same education. In the equal opportunity culture, on the other hand, educational opportunities are adapted to meet the needs of students with different interests and abilities. Equity is perceived to be achieved by ensuring that students who vary by race, gender, ethnicity, and socio-economic background have equal access to opportunities to develop their abilities. For example, in the United States achieving equity has been a major goal of the Jacob Javits legislation (Berger, 1992). This legislation funded a variety of projects that designed better ways to identify (Borland & Wright, 1994; O'Tuel, 1994; Maker, 1996) and serve (Baldwin, 1994; Hiatt, 1994; Tomlinson, Callahan & Lelli, 1997) students from minority and/or low SES backgrounds in gifted and talented programs.

In general, egalitarian cultures are either hostile towards gifted education or supportive of gifted education only in inclusive settings. Where egalitarian ideologies or politics are dominant in a culture, the

conception of giftedness espoused by program developers can make a big difference in the success of program development efforts. Egalitarians tend to reject gifted education when it is based on narrow conceptions of giftedness as innate, fixed, measurable intellectual superiority and to be open to gifted education when it is based on broader conceptions of giftedness that focus on multiple talents that are malleable and can be developed through appropriate educational experiences in inclusive settings. This trend can be seen in Australia and New Zealand (Braggert, 1993), Italy (Pagnin, 1995), Scandinavia (Urban & Sekowski, 1993), and many Asian countries (Wu & Cho, 1993).

Equal opportunity cultures, on the other hand, usually encourage the development of a broad smorgasbord of talent development opportunities (Feldhusen & Moon, 1995; Robinson, 1999). Hence programming options tend to proliferate in these cultures if resources are ample. However, when resources are scarce in a culture with an equal opportunity philosophy, the needs of the gifted are usually a lower priority than the needs of disadvantaged and disabled students. In South America and Africa, for example, the primary barrier to the development of programs for gifted children is not educational philosophy but resources (Alencar, 1993; Taylor, 1993; Guenther, 1995; Kolo, 1996). Much of the population in these countries is poor, the quality of the general education system is also poor, and there is little money available for infrastructure or staff training. Even if there is a belief that differential opportunities should be provided to students with talents to enable them to fulfill their potential, the human and material resources are not available to do so. In addition, given the immensity of the educational problems in these countries, the needs of gifted and talented students are usually seen as a lower priority than improvements to general education and/or special provisions for disadvantaged students (Taylor, 1993). Thus, in practice, it is usually the wealthier nations with an equal opportunity philosophy that provide the most support for gifted education.

### *Politics*

#### *Educational Policies*

An educational policy is a plan which provides written guidelines for action. The role of policy in gifted education varies greatly in different countries and is heavily influenced by political processes (Passow, 1993). In some countries education is highly centralized and one educational philosophy dominates (Burg, 1992; Goh, 1994; Stevenson, 1998). Other countries are characterized by locally determined educational philosophies with strong value conflicts among different subgroups (Braggert, 1993; Gallagher, 1993; Goguen, 1993; Purcell, 1995; Robinson, 1999). In countries with centralized educational systems,

national legislation and/or policy can have a tremendous influence on the development of gifted and talented programming.

In countries with decentralized educational systems, the climate for program development may vary considerably in different regions and/or in different historical time periods. In Canada, for example, gifted and talented programming varies by province (Goguen, 1993) and, in the United States, it varies by state and school district (Purcell, 1995; Landrum, Katsiyannis & DeWaard, 1998; Robinson, 1999). In Australia, gifted and talented programming tends to be influenced by the views of the political party that is in power, and thus varies by time as well as by region. Australian political parties with social democratic traditions favor policies aimed at equalizing social outcomes and don't believe that the absence of special programming handicaps gifted students; conservative political parties geared to a free market economy favor wider choice and a diversity of school provisions for gifted and talented students (Braggert, 1993). Countries that have traditionally had uniform egalitarian educational philosophies can sometimes be influenced by advocacy to consider modifying their uniform stance. For example, Finland, a country which has deeply held egalitarian values, has become more receptive to gifted education because of pressures from industry for a greater investment in excellence (Tirri & Uusikyla, 1994).

#### *The Interface Between General and Gifted Education*

When gifted students spend all or part of their time in general education classrooms, program developers must pay attention to the interface between gifted and general education. Research on what happens in general education classrooms for gifted and talented students in the United States has been discouraging and provides only limited guidance for persons wanting to develop differentiated, inclusive programming for gifted and talented students. For example, a survey of more than 7,000 third and fourth grade classroom teachers on their current differentiation practices revealed that few teachers were modifying the curriculum for gifted and talented learners (Archambault et al., 1993). When observations were conducted in 46 of the classrooms, the same research team found that 84% of the activities in the regular classrooms observed provided no differentiation for gifted and talented students and a majority of the teachers observed reported that they had no professional training in gifted education (Westberg, Archambault, Dobyns & Salvin, 1993).

A multi-site qualitative follow-up study was somewhat more encouraging (Westberg & Archambault, 1997). The study investigated ten schools with a reputation for successful differentiation of instruction for high ability students in regular classrooms. The teachers in these schools who were effective in

differentiating appeared to be life-long learners who were interested in continuous improvement of their skills, willing to embrace changes in their practices, engaged in some form of voluntary collaboration, and able to view their students as individuals rather than a mass. In some sites there was strong leadership support for the teachers' efforts at the school or district level. This study thus provides some guidance for the development of differentiated, inclusive education for gifted and talented learners.

Friedman & Lee (1996) studied three popular models that could be used to help general classroom teachers serve high-achieving/gifted students: the Enrichment Triad Model, the Multiple Talent Model, and the Cognitive-Affective Interaction Model. Only the Cognitive-Affective Interaction Model showed substantial gains in the cognitive complexity of teacher queries and student responses. An analysis by Johnson & Ryser, 1996 of over 675 articles appearing in gifted education journals and databases yielded only a small number of recommended practices that currently have research support for enhancing the learning of gifted students in inclusive programs. Their conclusions supported the use of problem finding, problem solving, and transfer strategies for the development of problem solving skills; competitions and special programs for improving thinking skills; and independent learning and interest centers for developing positive attitudes toward learning and creative productivity. Direct instruction was found useful for some groups of students and acceleration was considered useful for varying the rate of instruction. The authors expressed concern about the dearth of studies examining the effects of these practices on other students in the general classroom. They also recommended that future studies identify critical attributes of the strategies and methods that determine whether recommended practices are actually implemented in the classroom. Clearly more research is needed to guide the development of inclusive education programs that seek to adapt instruction for gifted and talented learners in general education classes.

Program developers also need to pay attention to the interface between the gifted and general education when specialized gifted programs are housed in general education settings, especially when gifted students spend only part of their school day in special programming. In such situations, increasing numbers of gifted program teachers consult and collaborate with general educators. Many gifted program administrators are also assuming new roles as collaborators with their general education colleagues, helping to guide the instruction of gifted learners in the regular classroom. Interviews have been conducted with respected individuals in gifted education and general education to explore ways in which the two fields might more effectively interface (Tomlinson, Coleman, Allan, Udall & Landrum, 1996). Collaboration between gifted

education and general education was viewed by those interviewed as a means of balancing concerns about equity and excellence, reinforcing the reality that both groups share common goals, and maximizing the strengths of both generalists and specialists to the benefit of the total school community. However, those interviewed also felt that gifted education must maintain a sufficiently separate identity to facilitate advocacy goals. Barriers to collaboration identified in this study included scarce resources, isolationism, and negative attitudes between the two groups.

Tomlinson (1996) has also argued that as a field, gifted educators "have not conveyed effectively how we do what we do when we do it well." To address this concern, Shore & Delcourt (1997) identified recommended practices in gifted education that have research support as distinctive to gifted education, practices needing further research to ascertain their uniqueness to gifted education, practices effective for gifted students but applicable to all students, and finally, practices for which there is no evidence for their uniqueness for gifted students. Five strategies considered uniquely appropriate to gifted education received strong empirical support: acceleration; career education, especially for girls; program arrangements influencing academic and affective outcomes; ability grouping; and high-level curriculum materials. Strategies that received moderate support as uniquely appropriate for gifted students included paying attention to cultural and social differences, learning styles, and affective development; individualized reading; investigation of real problems; supervised independent study; and rapid pacing. The authors categorized an additional 13 strategies as effective with gifted students but applicable to all students. They also identified thirteen strategies where there was insufficient evidence to make a case for their uniqueness for the gifted. This research can be utilized by program developers to make an empirically grounded case for the value of specialized programming for gifted and talented students, especially when that programming emphasizes strategies that have been documented to be uniquely appropriate for such students.

In summary, program developers need to be aware of issues surrounding the interface between general education and gifted education and strive to develop a collaborative relationship with general educators. The issues that must be addressed to achieve a cooperative relationship between gifted and general educators vary by culture, context, and type of programming being implemented. Issues related to the interface are particularly important when programs for gifted students will be housed in general education settings, when gifted students will be spending only part of their time in special programming and the rest in a general education settings, and when general educators are opposed to special programming for gifted and talented students.

### Attitudes of Stakeholders Towards Gifted Education

It is important for program administrators to monitor the attitudes of stakeholders and the general public toward gifted education. Unfortunately, a review of the research on attitudes toward gifted education revealed no consistent predictors of stakeholder attitudes (Begin & Gagne, 1994). Therefore, it is essential for program developers to monitor stakeholder attitudes empirically. In the United States, a recent Gallup Organization national survey suggested that the general public as well as parents of school age children were more supportive of using public school funds to provide services for students with learning problems than for students who were gifted and talented when both types of programs were perceived as competing for the same funds (Larsen, Griffin & Larsen, 1994). However, in a situation where funding for gifted children would not diminish what was offered to average and slow learners, nearly 85% of the general public was supportive of special funding for gifted and talented programs. This kind of information can be very helpful to advocacy and program development efforts. When information about public opinion is not available through large, national surveys, program administrators may want to administer a local needs assessment to assess stakeholder attitudes toward gifted and talented programming.

### Principles of Educational Change

Those responsible for program development also need to be knowledgeable about educational change theory. Much is known about the educational change process and those who are most effective in facilitating change (Moon & Swift, 1989; Maier, 1993). Both bottom-up and top down efforts are necessary to bring about lasting change (Fullan, 1993). Goals that are effective in influencing change do not have a single solution but recognize a variety of alternatives and are accompanied by the resources needed for implementation (Sarason, 1996). Although building-level administrators are key to change in schools, teachers, curriculum coordinators, and others are also an integral ingredient in the change process for education and must be viewed as such and prepared as leaders (Hord, Rutherford, Huling-Austin & Hall, 1987; Tietel, 1996). Boles & Troen (1996) have defined five areas of leadership development critical for encouraging teachers' growth: pedagogical innovation, pre-service teacher education, curriculum development, research, and governance. When program developers are aware that their efforts will require substantial changes in an educational system, they would be wise to spend some time reading the educational change literature prior to beginning their program development efforts.

### Legal Rights of Gifted Students

Although relatively few cases involving the rights of gifted students are heard in judicial systems around the

world, program developers need to be aware of the laws governing student rights in their jurisdiction (Ford, Russo & Harris, 1995). For example, underrepresentation of ethnic minority groups in gifted programs poses potential legal challenges to identification systems that under-identify ethnic minorities in the United States (Brown, 1997; Ford, 1995). The Office of Civil Rights (OCR) in the Department of Education in the United States is responsible for helping to resolve issues of discrimination with respect to gifted students. The primary purpose of the OCR is to investigate the compliance of school districts with federal legislation (Marquandt & Karnes, 1994). The OCR has investigated cases involving protected groups such as ethnic minorities and disabled students in four areas of gifted education: admission to gifted programs, identification procedures, placement in gifted programs, and procedures involving notification, communication, and/or testing of gifted students (Karnes, Troxclair & Marquandt, 1997). Program developers need to be aware of the laws governing the rights of special populations of gifted students in their area so they can ensure that the programs they develop protect those rights.

## The Development Process

### Introduction

The contextual issues discussed in the first part of this chapter influence all aspects of gifted program planning and implementation. Because theoretical, cultural, and political issues pervade the design process, program design is most effective when it is contextualized. General principles can be derived from theory and practice, but they must be modified to fit specific situations. Hence the focus of the remainder of the chapter is on *situated program development*, defined as program development that occurs in a specific local context and addresses that context throughout the development process.

The development of a program for gifted and talented students is a complex endeavor that involves the mobilization of human and material resources and is often controversial. Some aspects of the development process are inherent in the nature of the task. For example, a well-designed program must specify identification procedures, program goals, and a program format (Borland, 1989; VanTassel-Baska, 1998a). Other aspects of the program development process are more strategic. They are designed to facilitate the change process in a specific context. For example, including a wide variety of stakeholders on the development team is a strategy that can increase support for a new gifted program (Moon & Swift, 1989; VanTassel-Baska, 1998a). Program developers need skill in change facilitation, planning, and program design strategies. Strong change facilitation strategies lead to broad-based support for gifted and talented programs and program longevity; strong planning and

design skills lead to coherent, theoretically sound programs.

### *Change Facilitation Strategies*

#### Advocacy

In an environment where prevailing attitudes are opposed to any form of special education for gifted and talented students the first stage of program development may be a prolonged period of advocacy. An advocate has been defined as "one who supports, defends, maintains, and convinces with knowledgeable arguments in favor of a cause" (Gifted, 1998, p. 8). The role of advocacy is to draw attention to a need (Maier, 1993). Advocacy is a political process that can have an impact on the creation of policies and legislation favorable to gifted education as well as on local program development efforts (Dettmer, 1991; Riley & Karnes, 1991; Maier, 1993; Purcell, 1995). Where cultural values or educational policies are unfavorable to gifted education, a period of advocacy may be necessary prior to beginning program development efforts (DeLeon & VandenBox, 1985). It has been the experience of many nations around that world that advocacy must precede program development because program development simply does not occur when the prevailing educational philosophy is opposed to any form of special educational services for students with high abilities (Braggert, 1993; Stevenson, 1994). An effective advocacy effort can pave the way for vigorous program development. Even when educational philosophies and policies are favorable to gifted education, ongoing advocacy and attention to public relations can help enhance the viability and effectiveness of gifted and talented programming (Dettmer, 1991; Karnes & Riley, 1991; Renzulli & Reis, 1991).

Advocacy, like program development, is a problem solving process. Maier (Maier, 1993) has identified the steps in advocacy problem solving as follows:

- (1) A problem emerges
- (2) People gather to discuss the problem
- (3) Advocates present the issues to others to raise awareness
- (4) A multiplication of concern builds and creates power forces
- (5) Strategic intervention ends in action.

The goal of advocacy efforts on behalf of gifted and talented students is usually to bring about educational change (Maier, 1993). Therefore, persons attempting to develop programs for gifted and talented students should be familiar with the principles of educational change (Moon & Swift, 1989). More specific guidance on advocacy procedures is beyond the scope of this chapter. The interested reader is referred to Moon & Swift, 1989; Dettmer, 1991; Karnes & Riley, 1991; Riley & Karnes, 1991; Troxclair & Karnes, 1997;

California Association for the Gifted, 1998 for more concrete suggestions and information on how to advocate effectively for gifted and talented students.

#### Leadership

Gifted programs can be conceptualized as educational innovations (Goh, 1993). The planning and implementation of a gifted program requires changing existing educational systems, beliefs, and structures. Scholars in both business and education have found that strong leadership is a key factor in successful efforts to implement innovations in institutional settings (Peters & Waterman, 1982; Tuttle & Becker, 1983b; Peters & Austin, 1985; Moon & Swift, 1989).

Two types of leadership have been recommended in the institutional change literature: (a) 'champions' who are committed to creating change and given sufficient leeway by the relevant institutional structures that they can do so (Peters & Austin, 1985; Moon & Swift, 1989), and (b) broad-based advisory groups with representation from various groups of stakeholders that can steer program development efforts that flow from policy changes (VanTassel-Baska, 1998a). The role of a *champion* is to take responsibility for initiating and overseeing the change process. When there is a policy mandate for change in place, champions may be appointed by the policy makers. When there is not, champions often arise from the ranks of gifted education advocates. However, it is difficult for a champion to provide leadership for program development efforts unless they have some official role or position within the institution they desire to change, i.e. have been elected to a public office or are employed by a ministry of education or school system. If a school district has a coordinator or director of gifted education, that person is in an ideal position to be the champion for the development of new gifted program components (see for example Moon & Swift, 1989). Similarly, university professors with positions in gifted education can serve as champions for the development of university-based gifted programs (Stanley, 1997; Wood & Feldhusen, 1996) and members of ministries of education can serve as champions for national efforts to develop gifted programs (Burg, 1992; Goh, 1994). Teachers (Powley & Moon, 1993; Whitman & Moon, 1993) and members of state or national associations for the gifted (George, 1992) can also champion program development efforts.

The role of a *broad-based advisory group* is to address key issues that affect the program development effort and participate in all aspects of the planning process (Juntune, 1982; Tuttle & Becker, 1983b; Moon & Swift, 1989; VanTassel-Baska, 1998a). For district-level program development, VanTassel-Baska (1998a) recommends that the advisory committee include representation from administrators, teachers, parents, gifted students, pupil personnel services (counselor,

social worker, psychologist), and community members (business, arts, and professional). Additional relevant stakeholders for regional or national program development efforts would include representatives from regional departments of education, government officials, and university professors. The purpose of the broad-based advisory group is to provide diversified input into the program planning process and increase ownership in the new program.

### *Planning Strategies*

#### Needs Assessment

Situated program development requires a thorough needs assessment (Borland, 1989). The purpose of the needs assessment is to gather information on the program development context so that program development efforts can be tailored to that context (Boyd, 1992). Elements of the program development context that should be assessed include: (a) regional or national policies on gifted education or the lack thereof; (b) attitudes of stakeholders toward gifted education; (c) the incidence of giftedness types and levels; (d) existing educational practices; (e) material and financial resources and constraints; (f) human resources and constraints. Ideally, all of these contextual elements should be assessed by program developers prior to beginning the design phase of program development.

Methods of assessment include document analysis, reviews of the literature, surveys, interviews, observations, and analysis of student records. Document analysis is particularly appropriate for the examination of relevant gifted education policies. Such policies should be analyzed to determine whether they are mandatory or advisory in nature, and how they will facilitate or inhibit program development efforts. Curriculum materials can be examined to determine how effective the existing curriculum in specific subjects is in challenging the most able students in that domain. In some parts of the world, document analysis can be used to assess material and human resources because statistics on these resources are collected and analyzed on a regular basis. Where documents are not available, surveys, interviews, and/or observations can be utilized for the same purpose. However, these methods are more time and labor intensive so decisions will need to be made about which areas are the most important to assess in order to complete the needs assessment in a timely manner. Reviews of the literature can provide information on the status of programs for gifted students in other states (Purcell, 1995) or countries (Part VI, this volume); alternate conceptualizations of giftedness (Gardner, 1983; Sternberg & Davidson, 1986; Benbow & Lubinski, 1996; Neisser et al., 1996); different program models (Renzulli, 1986a; Maker & Nielson, 1995); and the steps involved in program design (Borland, 1989; Goh, 1993; VanTassel-Baska, 1998a).

Surveys are especially helpful in assessing attitudes of stakeholders toward gifted education. Surveys require careful construction if they are to provide reliable and valid data (Fink & Kosceoff, 1985). For example, it is important that items be easily understood by the respondents (Borland, 1989) and constructed in a way that will facilitate analysis (Fink & Kosceoff, 1985). If program developers are not trained in survey design, they should consult methodological texts and/or collaborate with a researcher in developing their needs assessment questionnaires and analyzing and interpreting the results.

An analysis of student records, particularly standardized testing results, can provide a rough guide to the numbers of students who need special services in the academic areas. Existing standardized test results are usually less useful in providing information on the highly gifted population. To estimate numbers of students with high levels of giftedness, tests with a high ceiling and/or off-level tests must be used (Benbow & Lubinski, 1997; Silverman, 1998). In addition, standardized tests are also not good guides to many important talent domains such as leadership, creativity, and the visual arts (Clark & Zimmerman, 1984, 1987; Sternberg, 1993). Estimating the number of students who are talented in these domains is far more difficult than estimating the number intellectually talented students. Surveying parents and/or teachers can yield a very rough estimate; however, surveys will probably underestimate the true talent pool because many children with talents in these domains are not given sufficient encouragement to develop their abilities to the point where they would be evident to parents and/or teachers. Hence, estimates obtained by surveying parents and teachers on the incidence of talent in areas such as music, art, creative writing, leadership, and creativity should be considered conservative.

#### Development of a Shared Philosophy

In countries, such as the United States (Purcell, 1995; Robinson, 1999), Australia (Robinson, 1992a; Braggert, 1993), and Canada (Goguen, 1993), where there is no national mandate for gifted education and considerable latitude is given to individual school districts to develop programs for gifted students that fit the local context, a key early phase task in local program development efforts is the creation of a shared philosophy of gifted education (VanTassel-Baska, 1998a). The development of a philosophy of gifted education can occur concurrently with, before, or after the needs assessment, but should precede the creation of action plans for the development of specific program components. The process of creating a formal philosophy statement involves discussion of the conceptual, political, and cultural issues discussed earlier in this chapter, as well as issues more specific to programming like the relative value of acceleration and enrichment in developing talent. The goal is to create consensus

around a shared philosophy of gifted education. Ideally, this process will be undertaken by a broad-based committee of stakeholders so that diverse viewpoints will be represented. The process of shaping a shared philosophy can clarify areas of agreement and disagreement among stakeholders and help build ownership in gifted programming within the specific context where services will be provided (Moon & Swift, 1989). The end product should be a formal philosophy statement that includes a working definition of giftedness and summarizes the educational philosophy that will guide the development and implementation of specific program components in that context (VanTassel-Baska, 1998a).

In countries where a particular philosophy of gifted education is mandated by state or national policy documents, as in Korea and Japan (Wu & Cho, 1993; Stevenson, 1994; Stevenson, 1998), a different approach is needed. Instead of creating local philosophies of gifted education, program developers must either translate the national philosophy into effective programming in specific school contexts and/or advocate for more effective national policies prior to beginning program development efforts.

#### Action Plan

Once the needs assessment has been completed and a philosophy of gifted education developed or adopted, the program developers need to create an action plan. The action plan is a blueprint for program development in a specific context over a specific time period. An action plan should include the following information:

- (1) The formal philosophy statement.
- (2) Goals of the overall program development effort
- (3) A brief description of the major tasks to be accomplished in achieving the goals with the persons(s) responsible for each task
- (4) Timelines for each aspect of the overall project
- (5) Projected budget
- (6) Evaluation procedures for each major task/component of the plan
- (7) Process for periodic revisions of the action plan after implementation begins.

Once the overall action plan has been written and approved by the relevant governing bodies the design and implementation of specific program components can begin.

#### Design Strategies

Using the strategic planning strategies suggested above can help galvanize broad-based support, elicit planning priorities from various stakeholder groups, and provide a contextualized structure for the design of program components. The component design and implementation process frequently involves many practical decisions such as who will be in charge of the program,

how the program will be delivered, how it will be funded, how students will be identified and served at various developmental levels, what will be taught, and who will teach it. At this stage of program development, it is essential that the contextual issues be integrated into a design for a specific program component that considers local, state, and/or national policies as well as the results of local needs assessments.

To a great extent, the success of the implementation process is linked to the gifted specialist or program administrator who will be directly responsible for program implementation in a specific context. Changes in educational reform have transformed the role of the gifted specialist in many regions (Hertzog, 1998), giving these individuals more responsibility as change agents. From very small communities, where there is only one gifted specialist who is also responsible for teaching, to large metropolitan programs that include a range of specialists in charge of different delivery systems, the competencies and skills needed by gifted specialists share some common features. Each serves as an advocate for gifted students and as a matchmaker seeking to match students' identified strengths and talents with program options that meet their needs. The gifted specialist may be expected to provide direct instruction, co-teach or identify resources for other program teachers. In larger programs, the gifted specialist may also have responsibilities for managing the program budget, overseeing both formative and summative evaluation of the program, providing professional development opportunities for staff, parents, general education personnel, families and the community. If at all possible, the gifted specialists who will be responsible for overseeing the implementation of a new gifted program component should be involved in all stages of the design of that component.

The array of program options available in gifted education can be overwhelming (Renzulli, 1986a; Maker & Nielson, 1995). Though seemingly convenient, a packaged approach to the design of program components can ignore important contextual needs identified during the planning phase and may result in a gifted program that is viewed as out of sync with the community's larger array of educational programs and services. In the situated approach to program development program developers are charged with fashioning program components that are tailored to local situations. Situated program development also requires a systems approach to the selection of program formats to prevent the proliferation of fragmented and marginalized services that characterized much of the early development of gifted programs in the United States (Cox, Daniel & Boston, 1985; Borland, 1989). The situated approach ensures that gifted program components can be integrated into the larger educational system (Borland, 1989; Moon & Swift, 1989). For an example of the use of the situated approach to the

development of a multi-faceted middle school program in a single school district in the United States see Moon & Swift, 1989.

#### Funding issues

Program development must balance vision with pragmatism. Funding is one of the most important factors on the pragmatic side of the program development equation. For successful implementation, funding must be considered during the design stage. Generally, funding for gifted and talented programming comes from one of four sources: national or regional legislation; ministries of education; local allocations from a general education budget; or special, experimental projects.

Currently there are several countries that have broad-based, legislated, national funding for special education, but few that have broad-based, national, funding for gifted education. In the United States, for example, programs for special education students have high levels of national funding, but gifted education programs have been developed without federal funding. In most cases, gifted program costs in the United States are supported by a combination of state and district funds, with the greatest percentage of the funds used for personnel (Gallagher, Weiss, Oglesby & Thomas, 1983; VanTassel-Baska, 1998a). A similar situation exists in Canada (Goguen, 1993) and Australia (Braggert, 1993). In these countries program development most often occurs at the local level and it is imperative that the budget consequences of the components designed be carefully considered. In general, program design proposals must include realistic budgets in order to be approved by local school boards. In addition, advocacy to increase both regional and local funding availability may be required.

In other countries such as Singapore and Korea, categorical funding is available for gifted education through national ministries of education. The most successful program development efforts in these countries occur at the national level through the ministry of education and there is less support for local program development efforts in state supported schools (Wu & Cho, 1993; Goh, 1994). Occasionally, both national and local funding are available for gifted education. In Israel, for example, some programs, such as special schools for mathematically, scientifically, and artistically talented students, are funded entirely by the national government and others are partially funded by local school districts with the encouragement of national policy (Burg, 1992).

When legislation or ministry of education policies provide regional funding for gifted education, funding formulas can vary. Sometimes a set amount of dollars is allocated to gifted programming, which may necessitate a cap on the number of students served. In other cases, a weighted model is used based on a formula that includes such variables as the type of exception-

ality and the hours of services provided. A new model that was recently developed in the United States uses the services needed by the student and the intensity of the student's need as the key variables in determining program costs. In at least one state where this approach has been used, the model has helped create a more student-centered approach to programming. Program developers must pay attention both to what funds are available and to how those funds are allocated.

A final source of funding in many countries is special project funds. Such funds have supported demonstration projects for serving disadvantaged gifted students in the United States under the Jacob Javits Act (Berger, 1992; Gallagher, 1994); a longitudinal study of experimental, individual and group programming options in China (Zha, 1993a, 1993b, 1997); and a large-scale project to identify and develop science talent in Siberia (Masharov, 1993). Program developers need to find out whether such funds are available in their area. If they are, developers should consider whether there is a match between the goals of the special project and local needs. Where a match exists, it may be worthwhile to apply for special project funds to support program development efforts. However, such funds are usually limited in duration. Therefore, a plan also needs to be created for financing the new program when the special project funds terminate. A more ambitious approach to special project funding involves attempting to convince funding agencies and/or legislatures to develop a new, funded special project to support the type of programming envisioned by the developers.

Unfortunately, in far too many countries, scarce financial resources for education in general, and gifted education in particular, are a major barrier to program development (Alencar, 1993; Taylor, 1993; Ekiert-Grabowska, 1994; Kolo, 1996). In these countries it is particularly important for program developers to pay attention to the cost-effectiveness of gifted programs and/or seek a source of special project funds.

#### Identification Procedures

Although needs assessments, advocacy efforts, and stakeholder input can help establish a common understanding of the target population that a gifted program is intended to serve, the determination of identification procedures can still be one of the most controversial aspects of program development. By definition, an identification procedure is an operational definition of giftedness and therefore subject to all of the controversy surrounding the construct of giftedness discussed earlier in this chapter. The difference between an identification procedure and a definition of giftedness is that an identification procedure is an operational definition of giftedness for the purpose of identifying students who would benefit from a particular gifted program. Prior to designing an identification procedure for a particular program component, pro-

gram designers should have defined the domains and levels of giftedness that will be served in the program.

One of the most important criteria for evaluating identification procedures is the degree of 'fit' between the procedures and the program component. In other words, an identification procedure should identify students who need and would benefit from the program. In addition, identification procedures should include at least two stages and multiple methods of data collection (Tuttle & Becker, 1983a; Gallagher & Gallagher, 1994; VanTassel-Baska, 1998b). The first stage is usually an inclusive screening process to find all students who might possibly benefit from the program that will be offered. In the second stage, additional data may be collected and the final selection decisions are made. A well-designed identification procedure also has formal appeal and exit procedures and is revised periodically (Moon, Feldhusen & Kelly, 1991).

The use of multiple identification criteria is strongly recommended (Feldhusen & Jarwan, 1993). As of 1992 in the United States, 34 states were using multiple criteria for ascertaining a student's eligibility for the gifted program (Coleman & Gallagher, 1992a). A position paper developed by the National Association for Gifted Children stated:

Given the limitations of all tests, no single measure should be used to make identification and placement decisions. That is, no single test or instrument should be used to include a child in or exclude a child from gifted education services . . . Best practices indicate that multiple measures and valid indicators from multiple sources must be used to assess and serve gifted students'. (NAGC, 1997)

Both formal and informal sources of data can be used to provide identification information (Spicker, 1987). *Formal sources* include standardized achievement tests, personality measures, normative behavioral checklists, and group or individual intelligence tests. *Informal sources* include portfolios of student work, authentic assessments, interviews, criterion-referenced rating scales, and parent/teacher/peer/self nominations. It is also a good idea to use the information gathered during the identification process to inform instructional planning. When used to plan and deliver instruction, knowledge of students' abilities can have a positive impact on student performance (Sternberg, Ferrari, Clinkenbeard & Grigorenko, 1996).

*Issues in Identification.* Issues in identification include: (a) equitable identification of students of different genders, ethnicities, and socio-economic background; (b) measurement concerns; (c) data aggregation and decision making concerns. Identification decisions are 'high stakes' decisions because they impact the lives of individuals. Therefore, each step in the procedures must be carefully reviewed to insure

that they are equitable for different subgroups (Frasier, 1991; Baldwin, 1994; Borland & Wright, 1994; O'Tuel, 1994; Plucker, 1996). For example, teacher nomination has consistently contributed to the under-inclusion of economically disadvantaged and minority students in U.S. gifted programs due to low teacher expectations and the type of impoverished schools that such students are often attending (Frasier & Passow, 1994; Frasier et al., 1995). Those responsible for overseeing the identification process must insure that teachers and staff become knowledgeable about the diverse ways in which gifted characteristics, behaviors, and indicators may be exhibited. The process must include a variety of individuals from various contexts who are invited to refer or nominate students and provide educational settings that can stimulate early signs of giftedness through students performances that can be observed in classrooms.

There are a number of measurement issues that can affect the validity of an evaluation procedure. The most important is validity with respect to program goals and services (Feldhusen, 1991; Feldhusen & Jarwan, 1993). Other measurement concerns frequently cited in the literature include *reliability*, especially for locally constructed and nonstandardized assessment techniques; and the *ceiling effects* on many standardized tests that make it difficult to distinguish levels of giftedness among the highly gifted. (Feldhusen, 1991; Feldhusen & Jarwan, 1993). *Developmental appropriateness* is also a measurement issue (Zorman, 1998). For example, Kolo (1999) studied instruments suitable for nominating potentially gifted preschoolers in Nigeria found that instruments designed specifically for the age group being targeted that had been modified for use by making more relevant item descriptors were more effective than instruments that had been locally developed for older students. For assistance in the challenging process of selecting standardized instruments appropriate for identification of gifted students, readers are encouraged to use Callahan, Hunsaker, Adams, Moore & Bland's (1995) careful review of identification instruments and Callahan, Tomlinson & Pizzat's (1995) discussion of innovative approaches to identification.

Data aggregation techniques and methods of making selection decisions are also controversial. For example, the use of matrices where points are assigned to diagnostic data in order to categorize them or produce totals have been criticized because such aggregation systems can distort the underlying raw scores (Feldhusen, Baska & Womble, 1981; Feldhusen & Jarwan, 1993). A more reliable way to synthesize data from different instruments is to convert the raw scores to standard scores prior to aggregation (Feldhusen et al., 1981; Feldhusen & Jarwan, 1993). The strengths and weaknesses of professional judgement methods of decision making have also been debated in the literature. When using the professional judgement

decision making method with multiple selection criteria, it is important to make the weighting systems used by members of the selection committee explicit and uniform (Moore & Betts, 1987). In sum, the development of an identification procedure is a controversial, technical, and vitally important aspect of program development. If the program planning team does not include an expert in measurement and the principles of identifying talent, a consultant should be hired to assist with the development of the identification procedures for each program component that will be developed by the team.

#### Program Format and Curriculum

*Format.* One of the most important tasks in designing gifted program components is the selection of a delivery format and a curriculum that fit together and will achieve program goals for a targeted group of gifted students. The *format* of a gifted program is the administrative delivery system utilized. Examples of program formats include special schools (Burg, 1992), early college entrance (Robinson, 1992b; Robinson, 1997), pullout enrichment (Kolloff & Feldhusen, 1981), regular classroom with differentiation (Tomlinson, 1995), and after-school, Saturday, and summer programs (Goldstein & Wagner, 1993; Wood & Feldhusen, 1996). The format tells whether, how, and when students will be grouped for instruction but says little about what kind of instruction students will receive. Selection of a program format requires careful consideration of a number of factors including the program talent domain, the level of giftedness of the target population of students, cultural and family values, and resources such as funding, space, and personnel.

There are different cost differentials associated with the staffing demands of various program models. Hence, decisions about program format require particularly close attention to personnel resources. The flexible use of human resources has been suggested as a means of increasing the cost effectiveness of gifted programs. Planned use of community volunteers, differentiated staffing, and extended school day and year are all strategies that have been suggested as ways to make gifted programming more cost effective (VanTassel-Baska, 1998a). Selecting a program format that facilitates use of these cost-effective personnel strategies may make it possible to develop gifted programs in contexts where lack of funding is a major barrier to gifted education.

*Curriculum.* Curriculum describes the type of learning experiences students will have regardless of the delivery format. Curriculum development can be one of the most demanding aspects of the development of a gifted program component. Often there is no existing curriculum that will provide sufficiently challenging learning experiences for the target population of high

ability students so curriculum must be written by the program developers, perhaps with the guidance of outside consultants, a time and labor intensive task. Full consideration of the complexities of developing articulated and differentiated curriculum for a specific gifted program is beyond the scope of this chapter. The interested reader is referred to the following references for guidance on this crucial program development task: (VanTassel-Baska, 1992, 1994; Maker & Nielson, 1996).

*Developmental Issues.* Those responsible for planning programs for gifted students must carefully consider the developmental needs of the age group of students for whom a program is intended, e.g. young gifted children vs. gifted adolescents. Although there is strong evidence supporting early recognition of giftedness (Kingore, 1998), early intervention (Diamond, 1988; Clark, 1998), and special programming for talented preschoolers (Karnes, 1983; Borland & Wright, 1994), the young gifted child is still frequently overlooked in the continuum of gifted programming (Smutny, 1998). For example, many educators and researchers are reluctant to recommend young children for psychometric testing and/or to trust the results of such testing. Those providing services to young gifted children will need to plan for children who may already know how to read, have advanced understandings of mathematical concepts and operations, and/or have a natural curiosity that requires opportunities for individualized investigations (Vydra & Leimbach, 1998). Responding to a child's readiness to learn is pivotal to the philosophy characterizing the learning environments considered best suited to working with developmentally advanced young children (Meininger, 1998).

The middle grades pose another series of developmental challenges that interface with a student's giftedness. Although there are many areas of agreement between gifted education and middle grades education (Chance, 1998), the current emphasis on heterogeneous grouping favored by middle schools contributes to the lack of challenge that many gifted students report when compared to elementary and high school (Coleman & Gallagher, 1992b; Tomlinson, 1994). Although this issue seemed to create a chasm between middle school educators and gifted educators in the early 1990s in the United States, recent reviews of the literature suggested that the debates have served as a forum for both fields to move beyond the rhetoric of differences towards a healthier focus on programs and practices (Rosselli, 1997; Tomlinson, 1997). For example, the 'touchstone' approach permits the testing of practices that may or may not be under the nomenclature of gifted education to insure that gifted middle schoolers' needs are met (Rosselli, 1997). This approach involves asking questions such as: Will the program services support excellence over mediocrity? Do the program offerings eliminate an artificial ceiling

for learning? Do the program offerings support students' varying learning needs, e.g. pace and style? Will the program offerings help students see in themselves a strength, passion or capability that can become a highly developed talent? The dialogue between middle school and gifted education in the United States has provided gifted program administrators with more information on the unique needs of this age group and creative new ways to meet the needs of gifted and talented middle schoolers.

### Staffing

*Teacher characteristics.* Although much has been written about desirable attributes of teachers for gifted programs, there is little empirical evidence supporting agreement on a definitive profile of an effective teacher of gifted students (Borland, 1989). Traits and characteristics such as hard working, high energy level, emotionally mature, self-confident, knowledgeable in the content area, highly intelligent, flexible, and creative are generally suggested with disclaimers that recognize the problems that such lists invoke (Feldhusen, 1997). In an attempt to move beyond this type of list mentality, which has limited usefulness for administrators charged with selecting personnel to teach gifted students, Olenchak (1990) has recommended that those hiring teachers for gifted programs include interview questions that create simulations in which candidates can demonstrate their use of reflection. Another suggestion for interview protocols can be drawn from the research of Armenta (1997) who found that the motivation for teachers to work with gifted students was fueled by strong feelings of identification with gifted children and memories of inadequate services during their own school histories. Thus, interview protocols inquiring about candidates' own backgrounds and motivations for seeking employment in gifted education may prove useful in the selection process.

The increasing use of consultation models as primary or supporting delivery system for gifted services, suggests that attention be paid to the qualities found in those who are able to successfully implement consultation and collaboration models. Critical attributes/behaviors needed for collaboration include: the ability to establish an easy rapport, the ability to communicate effectively, expertise in the area of gifted education, a view of the consultative relationship as mutually beneficial, resourcefulness, and empathy (Purcell & Leppien, 1998; Kirschenbaum, Armstrong & Landrum, 1999).

All too often staffing is limited to only those individuals who serve as teachers in a particular program. Feldhusen & Moon (1995) encourage the use of a systems-ecological perspective to involve families and communities, as well as school personnel, in programs for gifted students. In addition, guidance counselors, social workers, and other school support

personnel can assume important responsibilities relative to gifted programs such as: (a) matching student needs with appropriate services, (b) facilitating grade acceleration, and (c) serving as a catalyst for developing services that are none existent.

*Staff development.* An important responsibility of any program administrator is the design, facilitation, and evaluation of professional development activities. Effective professional development increases job retention, helps individuals prepare for role changes, enhances personal growth, and provides inspiration. No longer viewed as simply an exhaustive list of mini-workshops offered on a standardized inservice day, today's models of professional development are results-driven, systems oriented and influenced by constructivist approaches (Sparks & Hirsh, 1997). A full continuum of approaches to professional development must consider learning that takes place formally and informally, as well as within and outside school settings. In best case scenarios, teachers have opportunities to prioritize their own professional development needs while simultaneously supporting school agendas.

Although professional development has been recognized as one of the seven key directives for gifted education (Ross, 1993) and there is empirical evidence that teachers who receive training are more effective with gifted students than those who have not received training (Hansen & Feldhusen, 1994), professional development opportunities that address the needs of capable learners are still sorely lacking. Westberg and colleagues (Westberg et al., 1998) examined survey responses from over 1,200 school districts and found that:

- A very small proportion of school districts' total professional development dollars is spent on gifted education topics;
- The majority of districts do not evaluate the impact of their professional development practices in gifted education;
- Peer coaching between classroom teachers and gifted education teachers is seldom or never used to provide professional development; and
- Although more professional development experiences were found in districts with state mandates to identify and serve gifted students, there were no differences in terms of differentiated levels of professional development being offered for beginning, intermediate, and advanced levels of educators.

Similarly, the United States Council of State Directors of Programs for the Gifted has reported only 17 states with mandated training leading to teacher endorsement in gifted education (1994).

Ideally, candidates hired to teach in gifted programs should participate in formal professional coursework

designed to help teachers develop proficiency in gifted education. Towards this direction, NAGC has provided guidance through the publication of professional standards for graduate programs in gifted education (Parker, 1996). Program format has an influence on the type of formal training needed by teachers who will be working with gifted and talented youth. In countries where responsibility for meeting the needs of gifted students rests with general education teachers teaching in general education classrooms, it is desirable that those teachers receive coursework on gifted education during their *preservice* teacher education programs. When gifted education is delivered to adolescents in special schools, the teachers who will be teaching in such schools should have intensive *graduate* coursework in both gifted education pedagogy and their disciplinary specialization prior to and/or concurrent with their teaching assignment.

When such formal training is lacking, local staff development must be planned and implemented as a part of program development efforts. Dettmer & Landrum (1998) have distinguished between inservice and staff development in gifted education. *Inservice* tends to be a single event offered by an individual with expertise in gifted education. Staff development is a multi-year process that is targeted at school goals. *Staff development* involves careful planning based on assessment processes and is usually focused on goals that include involvement, commitment, and renewal. District personnel who oversee gifted programs embedded within general education settings have an especially complex mission in creating staff development programs that can be responsive to three different groups of stakeholders: veteran teachers in gifted programs, novice teachers in gifted programs, and general education and support personnel who by virtue of their interaction with gifted students need knowledge and skills relative to gifted education. For an excellent guide to planning and conducting local staff development see Dettmer & Landrum, 1998.

### Building Ownership

It is critical for administrators to develop ownership for gifted programs in ways that go beyond simply training the educational personnel directly involved in delivering services. The support of general education teachers, administrators, the participating students and their families are all integral to a situated approach to program planning. For example, use of instruments such as the Parent Experience Scale (Keirouz, 1992) can assist administrators in better understanding parental concerns, allowing for program revisions as appropriate. Similar processes involving other stakeholder groups are necessary as part of the climatization process which Goh (1993) describes as the development of trust and effective communication patterns within the organization in order to gain participation and support: "Climatization should be an ongoing

activity with different levels of intensity at different stages of program development and implementation, and aimed internally at the whole school environment as well as externally to the community outside of the school" (p. 576). Without this important step, a gifted program may become isolated from the rest of the educational system and be vulnerable to elimination.

In order to be effective in building ownership, gifted program administrators must be knowledgeable about change and innovation in educational systems (Moon & Swift, 1989; Goh, 1993; Maier, 1993). After all, new gifted programs are an innovation that need support from members of the school community to grow and develop (Goh, 1993). Use of the Concerns Based Adoption Model (CBAM), which views change as a process, can help administrators assess teachers' concerns about a new program and examine the relationship between the teachers' concerns and their actual practices in the classroom which can then be compared to the original design of the program innovation (Burns & Reid, 1990). This approach is helpful in examining the progress of a pilot program or when the program development spans a complex multi-year plan of action. It can help program administrators monitor multiple aspects of the program once it is implemented in order to resolve any problems that were not detectable at the design stage.

District personnel who attempt to change programs and services run the minefield of miscommunication, misidentification, and misapprehension due to the varying perceptions of stakeholders regarding the purpose and intent of gifted programs McGonagill (1997). Some of this confusion can be defused when district personnel pay adequate attention to the interaction of services across levels in ways that allow all stakeholders to recognize how each service at each level serves as an important precursor for future program endeavors and an integral step towards the program's goals (McGonagill, 1997). Often overlooked at the implementation stage are the students who will participate in the program. Orientation sessions for students and their parents can help clarify the goals and expected outcomes of the program, address fears and concerns, strengthen ownership for the program, and even serve as an ideal setting for collecting data that may be useful in a pre- and post-program assessment model.

Along with building ownership in the program, the program administrator, advisory committee, parents, teachers, and students can all serve as advocates for the program (Karnes, Lewis & Stephens, 1999; Kiger, 1998). Publicizing the program and its offerings and accomplishments helps others recognize the merit of special services for gifted students. A strong public relations approach can also facilitate a quick and effective response to legislative and policy initiatives that may impact the program (Riley & Karnes, 1991; Troxclair & Karnes, 1997). Holliday (1996) suggests

two types of public relations that are needed: a political approach that addresses needs of the program and seeks resources to support those needs and a more relational approach which effects the way the school personnel and community members work together to provide students with quality services. Again, it is clear that advocacy and program development go hand in hand.

### Accountability

Gifted programs are not exempt from the increased focus of the public and legislatures on accountability. In fact the opposite is true, because measures of student outcomes are increasingly being linked to resources. Gallagher (1998) suggests that accountability should be thought of in the spirit of "Trust, but verify." He also recommends that two levels of objectives be considered when measuring accountability: management objectives that include specific actions that the district intends to take to improve the program and program objectives that articulate expected changes as a result of the program, e.g. changes in student knowledge, skills, attitudes, and motivation. Both types of objectives are important, so Gallagher cautions that meeting management objectives means little if the program has fallen short in meeting its program objectives.

A well-designed formative evaluation can document that a gifted program is fulfilling its intention and provide information that can be utilized for program improvement (Callahan & Caldwell, 1984; Carter, 1991; Fetterman, 1993). Although many experts in the field believe that program designs should always include an accompanying evaluation design (Renzulli, 1975; Tomlinson & Callahan, 1993; Callahan & Caldwell, 1995), in practice program evaluation is among the most neglected aspects of program development (Hunsaker & Callahan, 1993). Many reasons have been suggested for the neglect of program evaluation including program vagueness and variability (Callahan, 1993), problems related to the use of standardized tests (Archambault, 1984; Reis, 1984; Robinson, 1991; Callahan & Caldwell, 1993), the complexity of gifted program outcomes (Carter, 1991; Callahan, 1993), and lack of time, resources, or technical assistance (Moon, 1996).

Although it can be difficult to evaluate gifted programs, it is essential to do so in order to ensure program excellence and viability. A full discussion of the principles of gifted program evaluation is beyond the scope of this chapter. For guidelines for planning effective evaluations of gifted programs see (Renzulli, 1975; Fetterman, 1993; Tomlinson & Callahan, 1993; Callahan & Caldwell, 1995; Seeley, 1998). For guidance on developing locally constructed instruments for evaluation purposes see (Nielsen & Buchanan, 1991). For good discussions of some of the complex issues that must be addressed in planning evaluations of

gifted programs see (Callahan, 1983, 1993; Carter, 1986, 1991).

### Conclusion

Situated program development is a complex task. The foundational stage of situated program development is a careful examination of both the conceptual foundations of the field of gifted education and the socio-cultural environment in which the program will be implemented. The second stage of situated program development involves strategic planning that results in a long-term action plan for the development of gifted and talented programming in a particular context. Finally, program components are custom-designed to develop talent in specific subpopulations of gifted and talented students in a particular context. When high levels of expertise in each aspect of program design are combined with a strong conceptual foundation and wise strategic planning, the result is exciting and effective educational programs for gifted and talented students.

# Academic Competitions and Programs Designed to Challenge the Exceptionally Talented

James Reed Campbell<sup>1</sup>, Harald Wagner<sup>2</sup> and Herbert J. Walberg<sup>3</sup>

## Introduction

Many chapters of this *International Handbook* concern in-school programs or conceptual frameworks designed for schools with gifted programs. The intent of both of these advances involves the development of talent. This chapter deals with a variety of out-of-school programs that are designed to challenge the exceptionally talented. We examine after school programs, competitions, including national academic Olympiads, and summer programs that have the same objective—the development of talent.

Bloom (1985) conducted a series of studies about how extraordinary talent is developed for concert pianists, sculptors, research mathematicians, research neurologists, Olympic swimmers, and tennis champions. His research teams examined the roles that teachers, parents, and out-of-school personnel played in the developmental process. One of the findings of these studies was that once parents became aware of their child's exceptional talent, they took a more active role in developing that talent. In many cases parents used out-of-school resources to develop their child's talent. They secured coaches, specialized teachers, or programs.

In this chapter we will continue this research focus by examining the ways teachers, parents, and other individuals (mentors) contribute to the development of academic talent.

### *A Framework for the Development of Talent*

A useful framework for the development and fostering of talent was proposed by Weinert (Weinert & Wagner, 1987). It may serve as a theoretical underpinning for programs for the talented. He concluded that effective measures to support the development of potential in young people should contain the following features:

- (1) Incitements: Curiosity, quest for knowledge and the interest in learning has to be incited by a multitude of attractive sources of information within easy access.
- (2) Options: A variety of options has to be available to engage in learning activities such as workshops, courses, summer programs or competitions.
- (3) Challenges: The difficulty and the level of the activities should match the level of ability so that very able pupils feel sufficiently challenged and have to exert considerable effort to reach the goal.
- (4) Incentives: The activities should be exciting and attractive and should provide the experience of success, rewards, and personal recognition.
- (5) Counseling: The young people, their parents and teachers should be able to obtain qualified information on the specific aspects of the students' potential and on available support programs.
- (6) Cooperation: Very able young people should be brought up and educated in a community of peers to experience a variety of social contacts to acquire social responsibility and to facilitate a harmonious development of their personality.

According to this framework, at least in the domain of intellectual abilities, it seems to be quite unrealistic to strive for a comprehensive, valid and reliable system of early assessment of potentials followed by a closed system of support programs. Instead, every effort should be made to provide a variety of measures to meet the needs of those who are eager to achieve and show a high degree of motivation. They should be able to be implemented pragmatically, to be easily accessible, differentiated and as open as possible.

In the ideal case such measures would be free of charge, the admission entirely voluntary and based on self selection and the treatment effective both for talent development and for the identification of the most able. Quite often, however, the specific properties of a support program and/or the large number of applicants demand a selection procedure.

There are essentially two ways to accomplish this task. One can create an arena where individuals are allowed to perform some task or set of tasks with those being selected as eligible whose level of performance is judged superior, by whatever definition or criterion. Alternatively, one can use a psychometric approach, relying on standardized tests that are, or at least should be, valid predictors of talent or high ability. The first approach is best exemplified by academic competitions; the second by the talent search.

In this chapter we examine the various facets of out-of-class programs and services, including the identification of high ability students through talent searches and academic competitions and special programs held after school, on weekends, or during summer holidays. While the chapter attempts to be inclusive in its coverage of the numerous out-of-class efforts currently in existence, detailed attention is paid to a small number of representative efforts in order to demonstrate in specific ways how these programs work and what they have accomplished.

### After school and Saturday Programs

#### *Parent Initiated Programs*

Parents are generally the first adults in a child's life to become aware of the child's talent. When the child enters school, it may become especially necessary for parents to provide supplementary activities by introducing the child to exciting and fascinating subjects. For many parents this task is rather intimidating. When they seek professional help and advice from pediatricians, teachers, school psychologists or educational counselors they are sometimes confronted with ignorance and prejudice about the talented child and imputations that they are 'pushy' parents.

Faced with the predicament of having to solve their problems more or less on their own, the parents of highly able children in many countries have established self-help groups in the form of associations such as the Gifted Child Society in the United States, the British National Association for Gifted Children (NAGC), the Deutsche Gesellschaft für das hochbegabte Kind in Germany, 'Pharos' in The Netherlands, 'Bekina' in Belgium, Association nationale pour les enfants intellectuellement précoces (ANPEIP) in France, or Elternverein für hochbegabte Kinder (EHK), Schweiz, in Switzerland.

Their joint aims are to:

- (1) give help, advice and information to parents of gifted children.
- (2) increase community awareness and understanding of the need to develop links with and information for local professionals such as teachers, social workers and medical practitioners.
- (3) provide an opportunity for gifted and talented children to meet and to pursue their interests in company.

- (4) facilitate contact with interesting and informed adults, offering children intellectual stimuli and an introduction to a wide range of interests.

Most of the associations have formed regional branches in order to better serve the needs of their members. Joint activities or enrichment programs for the children are usually run by adult volunteers, often a parent of one of the children or someone who is generally interested in the children's progress. They determine to a large extent the selection of activities available.

#### *Long-term Courses*

The array of courses offered by parents' associations is dependent on diverse, often chance, influences such as the number of children of a certain age group interested and willing to participate, the availability of course instructors, or special rooms, materials and equipment. A considerably more intensive form of provision are intellectually demanding long-term courses which take place in the afternoons, on weekends, or during holidays and which allow for a more systematic approach to a specific area.

As an example of this type of program, the 'Hamburg model' to find and foster mathematically able pupils will be described in more detail. In 1983, inspired by the work of Stanley and his group at Johns Hopkins University (Benbow & Stanley, 1983), a group of psychologists and mathematicians at the University of Hamburg developed an annual regional search for mathematically able pupils at the end of grade 6 (12-year-olds) (Wagner & Zimmermann, 1986). Selection criteria were: (1) German versions of the mathematical parts of the Scholastic Aptitude Test (SAT), and (2) a test of mathematical problem solving consisting of seven items both of which were taken during an examination of three hours' duration.

Pupils interested in the talent search received a preparation booklet in advance containing a complete version of the mathematical parts of the SAT to be worked through and attempted at home. About 40 students, that is 20 to 25% of the participants in the talent search, are annually admitted to the program that takes place on Saturday mornings at Hamburg University. The pupils work in small groups on challenging mathematical problems, with topics that vary from week to week. Expert secondary school maths teachers, mathematics students and mathematicians serve as instructors.

Rather than cover future curriculum material, the mathematical areas selected are predominantly those which pupils would find interesting and appealing and at the same time are important for the application of modern mathematics (e.g. graph theory, combinatorics, representation of numbers in connection with measuring, number theory, geometry and game theory). The problems are always chosen in such a way that they can

be extended to allow the development of a small mathematical theory and put pupils in an elementary research situation. New problem areas are introduced by a short paper including a few initial questions which help motivate the pupils. In addition to developing and practicing strategies for problem solving, special importance is attached to recognizing, formulating and perhaps solving subsequent problems.

Despite the considerable length of the course (participation is possible for up to six consecutive years) and the very challenging course work, the extremely low dropout rate together with the high rate of attendance and the very positive opinions that the pupils have of the course are all indications that this type of program successfully meets such pupils' needs. The program's success is due, in part, to the stimulus provided by the assignments and to the informal manner of working in small groups, in pairs, or even alone, which is quite unlike that at school. There is, on the other hand, an important social motive for taking part: in this group, pupils meet age-mates of a similarly high intellectual level and with mutual interests, without encountering incomprehension or even rejection. This type of separate provision for the highly able does not (as is sometimes implied) lead to social isolation but actually causes participants to feel less like outsiders. Most of them have for the first time been faced with a challenge commensurate with their capability and aptitude.

Funds from the German Federal Government initially helped to get the program started. After three years the program was self-supporting through contributions from the parents. Offshoots of the Hamburg project show that even when confronted with the typical transport and distance problems of a rural area the appeal of the program prevails despite the long journeys involved.

#### *Residential Programs*

The difficulties of commuter programs are overcome by residential programs which typically last from one to several weeks. This setting allows total involvement in a certain subject with intensive tutoring and a multitude of social contacts. Particularly in the United States, such programs have long been a fixed element of out-of-school provisions for highly able students (Olszewski-Kubilius, 1997). One of the most sound and consistent approaches was developed in 1979 at the Johns Hopkins University's Center for Talented Youth (CTY). It has been emulated by several institutions in the USA including Duke University, Northwestern University, the University of Denver, Arizona State University and California State University at Sacramento (Benbow & Lubinski, 1997).

By means of regional, national and international talent searches several thousand highly able students

are identified annually. They are eligible for three-week residential summer programs which in 1999 served about 4,000 participants at the CTY sites alone.

#### *The German Schülerakademien*

Inspired by the American approach to providing summer programs for highly able young people, in 1988 Bildung und Begabung, a non-profit German association, started residential summer programs for 16–19-year-old secondary school pupils, thus filling a critical gap between the last school years and higher education. Within a few years these 'Schülerakademien' (pupils' academies) have developed into an outstanding opportunity for academically highly talented and motivated adolescents which seems to be unique in continental Europe.

The main objectives of the academies are: (1) to offer several fields for scientific endeavor in order to develop and improve methods and abilities of knowledge acquisition, interdisciplinary thinking, research techniques and autonomous learning; (2) to challenge intellectual potentials to their limits; (3) to provide role models through encounters with highly creative, able, motivated and inspiring teachers and scientists; and (4) to experience a community of equally able and motivated peers, to develop lasting friendships and thus to accept one's own personality as valuable and 'normal'.

The 17-day academy typically embraces 90 boys and girls, each participating in one of six courses covering a broad range of diverse academic disciplines, e.g. mathematics, physics, foreign languages, creative writing, music, biology, chemistry, computer science, philosophy, history, economics, psychology, rhetoric and visual arts. The amount of time spent on course work within the 17 days is about 45 hours. The level of work is mostly comparable to advanced university seminars. Two teachers (scholars, expert school teachers or free-lancers) plan and conduct each of the courses with a minimum daily duration of 4–5 hours. The rest of the day is filled with additional optional activities such as sports, music, excursions, discussions and drama.

Between 1988 and 1998, 42 academies with over 3,600 participants were held in boarding schools which have proven to be ideal locations for these programs in Germany. Within a few days, each of the academies develops a unique and special atmosphere, filled with enthusiasm and motivation of both participants and instructors, characterized by intensive and open personal relations and discussions until late at night.

The participants are expected to pay a fee that covers board and lodging, the rest of the expenses being subsidized by the Government, by foundations and private donations. Financial assistance is available to

needy families. Pupils are invited to apply for a place after successful participation in one of the intellectually demanding competitions in Germany or being recommended by headmasters, teachers, educational consultants, or psychologists. In 1998, 1,015 (86%) of the 1,178 boys and girls who were invited applied for the 540 available places in six academies.

Extensive evaluations of the academies (Wagner, Neber & Heller 1995, Neber & Heller, 1997) have shown their long-lasting positive effects on the participants, especially with regard to their motivation, self-efficacy, self-assertion, self-reliance, cooperativeness and communication skills. Similar effects are reported from residential summer programs in the United States (Olszewski-Kubilius, 1997).

The major benefit of these programs seems to be that they provide opportunities for interaction with equally able and motivated peers. Pupils feel accepted often for the first time in their lives and many of them are astounded to discover how easy it is to communicate with and to make friends within this group. The results are frequently long-lasting relationships and communication networks.

Encounters with excellent instructors provide valuable role models for an academic orientation. They can be helpful in career counseling and might open perspectives into yet unconsidered professional areas. The intense atmosphere of residential programs is capable of activating and stimulating dormant potentials. Many of these pupils relate with amazement what they were able to achieve in a short time.

In short, these programs have a tremendously beneficial impact on young lives. It would be highly desirable to increase the number of such programs, as the current demand far exceeds the existing supply of places.

### **Academic Competitions**

Competitions are increasing by being made available to talented students in Europe, Asia, and the United States. In the United States 275 competitions (Karnes & Riley, 1996) are currently being used. These competitions have been developed in every academic area and in many non-academic areas. Some of these competitions are targeted at elementary school children, others concern middle school children, and others are reserved for advanced high school students. Campbell (1998) found that American teachers use these competitions to challenge their gifted students.

#### *Potential Benefits and Liabilities of Competitions*

Competitions are funded by governments, foundations, and companies to develop extraordinary talent. Maths, science, and engineering contests are conducted with the expectation of developing talent needed to supply the technical workforce (S & E work force). The S & E workforce is essential for a nation's economic health

and development. In the United States several of the high school competitions were initially developed after the Russians launched Sputnik. One of President Eisenhower's science advisors was Edwin Teller who urged the president to start academic contests that would get young people involved in the technical areas at early ages. This stimulus resulted in the initiation of several of the competitions that are still being used in America.

The chief benefit of these competitions for schools is their low cost. Competitions involving nationally administered tests can be done at very low costs per pupil. The supporters of competitions note that most societies are competitive. Certainly, businesses must, of necessity, be competitive, and the global economy has accelerated this process. Governments are also competitive not only in terms of their businesses but in many other areas. Competition exists even in academia where authors compete for publications and grants. Sports are competitive by definition; therefore, with all these levels of competition, it follows that competitions would emerge as a mechanism to uncover exceptional talent.

#### *Competitions in Europe, Russia, U.S., and Asia*

The Russians were the first to realize the potential of academic competitions and initiated the academic Olympics. The first academic Olympic program involved mathematics and was started in Leningrad in 1934 (Kukushkin, 1996). This Mathematics Olympic competition was extended to city programs in Moscow and Kiev in 1935. These Olympic programs eventually spread to the entire USSR and beyond. The Russians used these competitions to funnel talent into areas where they were needed. A student scoring exceptionally high on one of the academic Olympic exams was given automatic admission to some of the best universities. This admission placed the exceptional student in the Soviet S & E pipeline. In socialized countries national testing programs were conducted that assured the identification of a steady stream of gifted individuals. Once identified, these talents could be funneled into areas where development was needed.

#### *European Competitions*

In Europe, the Federal Republic of Germany probably has the most elaborate system of competitions for school children at all levels. Competitions are considered to be important and valuable additional instruments in the educational process.

They are relatively easy to administer and to organize, they can be made accessible to a broad number of participants and they can be differentiated to suit any level of ability. Competitions are an excellent tool to elicit, stimulate and challenge talents in many different fields. They are supposed to activate and

strengthen the inclination for the subject matter and thus to improve knowledge and ability. Struggling with the tasks of the competition enhances the abilities of working autonomously while researching, experimenting, problem solving, learning and practicing release energies and enhance perseverance.

By taking the challenge of a competition, the participants gain insight into their abilities and their position in comparison with peers beyond the confinement of their classroom and school. Coming together with other participants, they have the opportunity to meet similarly interested and able peers who are usually not so easily found. Attractive prizes like scholarships, summer programs, or money are additional incentives.

In Germany, there are more than twenty federal (nationwide) competitions and dozens of smaller competitions at the state or regional level. On the federal level well over 100,000 students participate annually either individually or in groups in disciplines such as mathematics, science (biology, chemistry, physics, technology, computer science, environmental studies), foreign languages, social studies, history, creative writing, music, composing, drama, film and video production. Most of these competitions are subsidized by the Federal Government, with a total allocation of c. 4 million Euro in 1999. In addition, a considerable part of the cost is covered by sponsoring foundations and industry. While most of the academic competitions are aimed at upper secondary school students (16+ years of age), there is, however, in most cases no lower limit for the age of participation thus granting admission to all kinds of accelerated talents.

Without doubt, one of the most remarkable competitions is the 'Bundeswettbewerb Fremdsprachen' (Federal Languages Contest), as it is a unique comprehensive approach to support acquisition and application of foreign languages among secondary school students. The contest was initiated in 1979 by the Stifterverband für die Deutsche Wissenschaft (Donors' Association for the Promotion of Science in Germany) as a means to encourage students to learn foreign languages and to become interested in other countries and cultures at an early age. It has been developed and administered by independent experts from universities, schools and industry. Since 1985, the Federal Languages Contest has been sponsored mainly by the Federal Ministry of Education and Research. Bildung und Begabung e.V., a non-profit-making private association, and is responsible for the organization and coordination of the contest.

The contest comprises four levels:

- (1) A group contest for students in grades 7–10 (13–16 years, in their third to sixth year of foreign language learning). The group contest encourages project work to produce a presentation (audio or video tape and additional written material) on a

self-assigned subject (cf. Blüm, Hertel & Schröder, 1992).

- (2) An individual junior contest for students in their fifth or sixth year of foreign language learning (15–16 years of age). It consists of an oral section (listening comprehension and oral production) and a written section (a cloze test, i.e. a text in which missing parts of words have to be filled in) and a creative writing task. The best participants in English usually demonstrate a higher proficiency than first year university students in English studies.
- (3) An individual senior contest for students in grades 11–13 (17–19 years) in which at least two foreign languages must be presented. This contest consists of four rounds over a period of twelve months. It begins with an oral production in two languages (e.g. explaining the situation depicted in a cartoon, reading a text and answering questions on the text). The second round is a written examination with elements of translating, writing and summarizing. The task of the third round is writing a 3000-word essay on a given subject within a six-week period. The final round consists of a one-hour multilingual debating session in groups of four together with language experts and of individual oral examinations (cf. Hertel, Joppich, Schröder & Stütz 1991). Placement in all rounds depends upon achievement only. The participants do not compete against each other as in a sports contest.  
Successful participants can expect a variety of prizes. Winners of a first prize in the final round ('federal winners') are granted a scholarship for university studies from the most prestigious scholarship foundation in Germany (Studienstiftung des deutschen Volkes). Second and third prizes consist of cash. Several prizes (e.g. travel grants, books, records) are awarded by foreign embassies for special languages. The Federal Minister of Education and Research annually awards a five-week stay in a summer studies program at a university in the United States to three participants who wrote outstanding essays on U.S. related subjects.
- (4) A group contest for apprentices and for students at vocational schools. Here, again, a presentation on audio or videotape is required which has to relate to their working sphere. Many of the entries are multilingual.

More than 20,000 students participate in these four contests each year, the main languages being English, Latin, French, Spanish, Italian and Russian. Additionally, special contests are offered to pupils who study Japanese or Chinese.

Some competitions are held at an international European level. To promote the idea of European integration the 'European Competition' has been held since 1954. Each year students at all age levels in 19

European countries receive identical assignments to produce a pictorial or written treatment of European perspectives in social, economic, political or cultural affairs. In Germany alone over 100,000 students participate.

Most European countries run competitions for young researchers in the sciences. In 1990 the most famous science competition in Germany ('Jugend forscht') was sponsored by 'Deutsche Bank' to initiate a European competition for environmental studies. Up to three entrants from (1998) 39 nations may participate in the 'Young Europeans' Environmental Research (YEER).

Another recent development was initiated by Romania in 1993: the Central European Olympiad in Informatics (CEOI) with (1998) Croatia, Poland, Slovak Republic, Czech Republic, Slovenia and Hungary as participating countries. Other countries are expected to join in the following years.

#### *Types of Competitions in the U.S.*

In the United States three types of competitions are currently employed. The first type uses teams of gifted students; the second type involves encouraging gifted students to do long-term independent research projects (preferably with scientists or scholars); and the third type utilizes a series of tests to identify the exceptionally talented.

The two most widely used American team competitions are Future Problem Solving and Odyssey of the Mind (Campbell, 1998). The Future Problem Solving Program has three levels of competition (junior, intermediate, senior) (Grades 4–12). The teams are given problems that require creativity and imagination to solve. Successful teams learn to problem solve together. The problems frequently deal with futuristic scenarios. This program has local, state (state bowls), and international competitions.

The Odyssey of the Mind also emphasizes solving problems and creativity. Five problems are presented each year which require unique solutions. The problems range from engineering problems to literature analyses. The age range extends from K-12 and is organized into four divisions.

The next type of competition involves individual students doing independent research projects. Local Science and Engineering Fairs are very common in the U.S. At the high school level the projects become more advanced with many students working directly with scientists, mathematicians, and scholars (see Campbell, 1985; 1988). This direct involvement with the 'producers' of technical knowledge has been accelerated by the Science Training Programs that are offered for talented students each summer throughout the United States. These programs are designed for advanced high school students to join research labs and participate in up-to-date research projects. These students become members of graduate research teams and serve as apprentices. The same process is used year-round for

high schools located near universities or research labs. These projects are written up by the high school students and entered in the different competitions.

There are three national project competitions in the U.S. of which the most prestigious is the Intel (Westinghouse) Talent Search (started in 1941). Each year this competition accepts applications from approximately 1,500 high school seniors. These applications must include descriptions of original research projects in mathematics, biology, physics, chemistry, engineering, or the social sciences (psychology, anthropology, sociology). The research papers follow standard scientific methods and scholarly reporting procedures.

The 300 best papers are selected by the Science Service as semifinalists. From this pool the top 40 (finalists) are then invited for a series of interviews in Washington, D.C. A final ranking is determined on the basis of the interviews, and \$330,000 (U.S.) in scholarships are awarded to the top finalists. Colleges and universities in the United States compete for the Intel winners (finalists and semifinalists). Their research skills are especially applicable at institutions that are committed to original research studies.

Over the 58-year history of this competition, 17,400 semifinalists and 2,320 finalists have been selected. The Science Service did a follow-up survey of the Intel finalists and found that they won five Nobel prizes, two Field Medals, and eight MacArthur Fellowships. However, the finalists comprise less than 13% of the Intel winners. There has been no comprehensive follow-up study to ascertain the number of the Intel winners in the United States S & E labor force.

Two other national research paper competitions are the Junior Science and Humanities Symposium (JSHS) and the International Science and Engineering Fair. The JSHS competitions are subdivided into 48 regionals, which are located in 50 states and Puerto Rico. The finalists from each regional attend a national meeting and compete for scholarships. Each year this competition involves more than 3,000 high school students (Grades 9–12). The national conference has 240 finalists and awards \$343,000 (U.S.) in scholarships. Many of these finalists are also Intel winners.

The International Science and Engineering Fair is the largest research paper competition. In 1995 this competition reached 1,021,936 high school students (Grades 9–12). This competition is organized with local school fairs, regional, and state fairs and one national fair. Those selected for the national fair number 1,200 students. Again, many students enter other competitions and have the opportunity to win other contests.

The other types of national competitions involve testing of select groups of high school students. One of the largest is the National Merit Exam which tested 1,200,000 students in 1998. The top 50,000 students were contacted, and a sifting was performed where

34,000 received commendations and 16,000 are designated semifinalists. A further sifting narrowed down to 15,000 finalists who received \$28,000,000 (U.S.) in scholarships.

Another national program (Study of Mathematically Precocious Youth-SMPY) tests 7th-grade students with the SAT-M exam (Scholastic Aptitude Test Maths). This program invites schools to test their top maths students. These talent search programs identify the most talented maths students and provide year-round activities and summer programs to help in developing this talent. These programs exist in every state and serve over 140,000 mathematically precocious participants (Goldstein & Wagner, 1993).

The other national testing programs are the Olympiad Competitions (maths, physics, chemistry). These competitions utilize multiple levels of tests to isolate very small sets of finalists. In maths, three levels of tests are used to isolate the highest scoring eight students (6 finalists and 2 alternates), and in physics and chemistry the same process is used to isolate talent pools of 20 students from which the international finalists are selected (5 for physics; 6 for chemistry).

A total of 2,226,436 high school students participated in the competitions listed above (although many high ability students participated in multiple contests). The total U.S. school age population in Grades 9–12 was 12,214,000, which indicates that a substantial percentage of talented students were involved in these competitions (Statistical Abstract of the United States, 1997).

### *Rationale*

All competitions operate under a series of assumptions that constitute a distinctive rationale:

- (1) Children with talent need to be identified early.
- (2) Competitions are needed because most schools do not have the differentiated curriculum or the resources that are needed to develop the talents of extraordinary students.
- (3) Contests will attract participants with extraordinary talent.
- (4) Contests will motivate the early development of talent.
- (5) Once developed, this talent is expected to contribute to society.

Every expert since Lewis Terman (1922) has called for the early identification of talent. Terman used IQ tests to identify the intellectually talented. He believed that with these tools schools could identify the gifted and then develop their talent accordingly. Unfortunately, Terman's expectations were never realized due to limited administration of the early IQ tests or to the failure of the schools to initiate programs that would develop the talents of those children that were identified.

The second assumption gets at the heart of the problem. Few would argue that schools have developed the differentiated curriculum or obtained the resources that are needed to develop the talents of the full range of extraordinary students. Perhaps this failing rests with the extensive range of talents (both academic and non-academic) that gifted students possess. Schools simply do not have the resources to accomplish this worthy goal.

The third assumption deals with the expectation that the talented will find out about the contests dealing with their special talent and this will stimulate their development (4th assumption). Both of these assumptions depend on getting the needed information to the students with the talent.

The last assumption—once developed, this talent is expected to contribute to society—is an open research question that is a vital topic to investigate. It must also be emphasized that in the United States millions of gifted students participate in academic competitions each year. Because of the sheer numbers that participate, it is crucial to see what the competitions achieve. The answer to this question can only come by conducting long-term follow-up studies that track down the winners of important competitions and determine the contribution they made to society.

Unfortunately, American schools have a poor record in evaluating gifted programs (Callahan & Caldwell, 1995). Campbell (1998) found that only 7% of the schools with gifted programs that he studied conducted rigorous evaluations. This reluctance to evaluate extends to the competitions. Many of the organizations sponsoring them operate on very limited funds and do not have the resources or the manpower to carry out follow-up studies. Furthermore the funding sources (governments, foundations, companies) might not want to conduct such studies when they realize the possibility that their investment might not be justified. It would be difficult to explain negative findings to government officials or to boards of directors.

### *Academic Olympiad Studies*

A definitive answer to this question can only come when each of the different competitions undergoes long-term follow-up studies of their adult participants by outside evaluators. But we will provide a partial answer to this question by presenting information about three retrospective academic Olympiad studies.

Campbell, Feng & Verna (1999) tracked down 15–27 years of winners of the American Maths, Physics and Chemistry Olympiad programs. These long-term retrospective follow-up studies asked the following research questions:

### *Research Questions*

Do the Olympiad competitions serve the national purpose? Do the academic Olympians make important

contributions? Do they fulfill their high potential? The specific questions we asked within this framework included: What careers do the Olympians select? Do they do well in their careers? Do the Olympians remain in the field originally identified? How many doctoral degrees were earned by the Olympians? How productive were the Olympians? How many publications and patents did they produce? Finally, we evaluated the effects of the Olympiad programs by asking the following questions: What effect did participation in the Olympiad program have on these talented individuals? Did it widen their horizons? Did it open doors for them? Were there negative side-effects?

To answer these questions we followed 229 Olympians through their college years to graduation (ages 15–22), into their graduate training (early careers) (ages 23–30), and finally onto their professional careers (career) (ages 30–46). They received information from substantial percentages of the national finalists (94% Math Olympians; 70% Physics Olympians, 68% Chemistry Olympians) (229 Olympians). Within the three age brackets there was much variation among the subject areas because of different starting dates for the programs. The Math Olympiad program started in 1972 and therefore contains the largest number of Olympians in the mature career bracket. The Chemistry Olympiad started in 1984, and the Physics Olympiad program started in 1986. These late starting points put more Olympians in the younger brackets. In the Physics study 49% of the Olympians are in the youngest age bracket, which means that fewer have had the time to establish publication records or to get advanced degrees.

One measure of success involves enrollment in the most selective colleges and the completion of college/universities degrees. The Olympians were successful in enrolling in the most prestigious colleges/universities in the United States (see Table 1). The institutions listed in this table constitute the most elite in the nation. The top five (Harvard, Princeton, MIT, U. C. Berkeley, University of Chicago) absorbed most of the Olympians and provided them with sound foundations for their careers. With their high GPA's and exceptional SAT scores, it is no surprise to find the Olympians at such institutions. However, a few of the Olympians had trouble completing their undergraduate degrees and some dropped out of college and took many years to finish. The majority finished their degrees within a four year period and enrolled in advanced degree programs.

The extent of the Olympians' graduate training is evident from the graduate institutions listed in the table. The same selective colleges are listed at the graduate level. One hundred and sixteen Olympians completed, or are in the process of completing, doctoral degrees (MD; Ph.D.; JD). The average time the Olympians take in getting their doctorate degree is approximately 8 years from their high school graduation year. The shortest time any Olympian earned a doctorate degree was 6 years; the longest was 13 years. Overall, 51% of the Olympians have received, or will receive, doctorate degrees (Math 57%; Chemistry 49%; Physics 41% (see Table 2). Among the doctorate degrees there are five law degrees. The percentage for the Math Olympians is more illuminating because of the ages of these Olympians. The other subject areas

Table 1. Colleges and Universities Attended by Olympians.

Number of Olympians in Subject Areas	87	51	91
Percent with Doctorate Degrees	57%	41%	49%

contain many more college-age Olympians who will probably enroll in doctoral programs. Terman (1954), in his monumental longitudinal study, found that 26.3% of 800 gifted males had their doctorate or law degrees. The Olympians far exceed this percentage.

Most of the Olympians select careers in academia—teaching at colleges or universities or doing research. These Olympians finish their doctorate degrees between 26 to 28 years of age and many go on to post doctorate experiences that take another two years.

Consequently, most of these Olympians do not formally start their academic careers before the age of 30.

How successful are these Olympians? One measure of post-secondary faculty and staff productivity involves tabulating the number of publications produced. Table 4 contains the total publication data for the 229 Olympians. The Olympians have produced a total of 2,921 publications. Most of these publications are written by the Olympians employed in colleges and

*Table 3. Olympians' Occupations (not in Colleges and Universities).*

Number	Occupation/Job Title
<b>Computer Occupations</b>	
4	Computer Programmer/Analyst

1	Independent film Maker

Table 4. Total Publications.

Age Cohorts	Olympiad		
	Mathematics	Physics	Chemistry
Ages 15–22 PreCollege/College	10 (1.4/person) N = 7	113 (4.5/person) N = 25	107 (3.5/person) N = 31
Ages 23–29 Early Career	231 (7.7/person) N = 30	141 (6.1/person) N = 23	401 (9.8/person) N = 41
Ages 30–46 Mature Career	1,622 (32/person) N = 50	14 (4.7/person) N = 3	280 (14.7/person) N = 19
Total Publications in Subject Areas	1,863 N = 87	268 N = 51	788 N = 91

universities, and most are in refereed journals. The Math Olympians published 1,865 items, the Chemistry Olympians produced 788 items, and the Physics Olympians produced 268. The bulk of these publications were written by Olympians in their thirties or forties.

The National Center for Educational Statistics has a national study underway of 11,000 higher education faculty in 480 institutions (National Survey of Post-secondary Faculty—NSOFF) (Kirshstein, Matheson & Jing, 1997). The NSOFF data for 1992 showed the average number of publications for all college faculty was 4.6 per year. However, the faculty publication rate was much higher at research institutions (7.35/year for public colleges/universities; 7.95/year for private ones).

Some Olympians have higher publication rates than the NSOFF faculty. Four of the Olympians have over 100 publications, and eight Olympians in their 30s have produced between 50 and 99 publications. These academic 'stars' are in positions of leadership. For example, one is director of Whitehead/MIT Center for Genome Research at 42 years of age and has already made contributions to cancer research. He has published 229 articles, research papers, technical reports, and two books, and serves on 12 editorial boards. Another 44 year old Olympian served as the editor for two journals, published one book, has 6 chapters in books, 51 articles in refereed journals, and 37 research papers. He is active in research dealing with electrical

and computer engineering projects and in 1994 served as a member of the Defense Science Board studying Cruise Missile defense.

By contrast, some of the Olympians may be underachievers. Thirteen of the mature career Math Olympians have produced less than 10 publications. Some of these Olympians are in fields where publications are irrelevant to performance. Still, some Olympians reported psychological problems or drug problems, which have undermined their productivity.

The Olympians' publication activities fit the pattern that Terman found in his longitudinal studies. Terman (1954) recorded the publications of 67 books and 1,400 articles and research papers for 800 gifted males. The average number of publications was 1.9 publications per person; for the Olympians the rate is greater at 12.8 publications per person. It must be emphasized that 69% of the Olympians are younger than 30 years old and can be expected to publish many more articles, books, papers, and secure more patents. The oldest cohort (ages 30–46), which has already produced 1,916 publications (26.6/person) can also be expected to continue to publish actively.

One factor involved in this high level of productivity is the mentoring done during the Olympians' undergraduate and graduate years. The disparity between Olympians who have been mentored and those who were not mentored is startling (see Table 5). The majority of publications was done by those who were mentored.

Table 5. Total Publications in Terms of Mentoring.

	Mentored %	Non-mentored %
Math Olympians	84	16
Chemistry Olympians	64	36
Physics Olympians	72	28

A substantial number of Olympians have careers outside academia. Some gravitate to science and engineering careers, a good number are employed in computer areas, and still others are employed in the business sector (see Table 3). How successful are the Olympians in the non-college/universities occupations? There is no way to determine the contribution made by the Olympians in the non-academic community, but the job titles indicate a number of responsible positions. The most successful might include the eight Olympians employed by financial institutions on Wall Street. One is an executive at the prestigious Salomon Brothers; one is a bond trader; one is an associate with Goldman, Sachs; and two are financial analysts with major banks. Two of these individuals are in charge of the research on derivatives. One of the lawyers is the council for the mayor's office in one of the largest cities in the U.S.

There are several Olympians employed in the computer industry. Three Olympians founded software companies. Two are currently the CEO of their companies, and another remains an executive with his company. Another Olympian is the executive director of a non-profit corporation.

A number of Olympians are scientists or engineers. One is a principal engineer with nine patents; another is a scientist at Los Alamos National Lab; two are researchers at the Bell Labs (AT&T); two others are senior scientists at IBM; and one is a scientist with DuPont.

Two of the Olympians are Talmud scholars. Four of the Olympians are teachers, two of these teachers co-authored two textbooks. Another Olympian founded a journal that is in its 12th year, and another is a correspondent with a science magazine. One Olympian performed with a musical ensemble at Carnegie Hall; another is an independent film maker.

Would the Olympians have turned out as well without the Olympiad programs? This is a fundamental question to ask the adult Olympians and their parents. It is also a question that should be asked by independent evaluators who have no connection to these programs.

Both the Olympians (76%) and their parents (70%) expressed the view that they would not have accomplished as much without the programs. When asked if the programs helped or hindered their acceptance of their talents, 76% of the Olympians and 74% of their parents concluded that the program helped. Only 4% of the Olympians and none of the parents thought it hindered the development of their talent in any way. Most Olympians (76%) and their parents (83%) reported that the program helped to increase their awareness of educational opportunities.

#### *Delayed Recognition*

The Olympiad programs had some profound effects on the participants. When asked to comment about what the Olympiad experience meant to them, many

responded with lengthy statements. Most of the Olympians had supportive families that nurtured confidence in their abilities, but to score in the top places in a national exam was a more important milestone for their confidence. They described their reactions to this achievement in these ways: "confirmation of my abilities," "realization I had potential," "confidence booster," "discovering I had the right to believe in my own abilities," "a chance to be recognized," "made me aware, for the first time, that my talent was really unusual," "validating," "confirmed my merit," "a more objective indication of my talent," "It helped me gauge my talent," and "First indication I had of how good I really was."

This theme is entitled 'delayed recognition' because so many of the Olympians did not realize the extent of their talent. Some of them had undervalued their capabilities and had set more modest goals for themselves. Their high scores on the Olympiad exams supplied them with much more confidence in their abilities. It also helped them to evaluate their potential more realistically and to set higher goals for themselves. The program also had several other benefits. After announcing the results of the exams, the Olympians were invited to an intensive summer training program. This training brought the Olympians in contact with other bright students and exposed them to stimulating presentations by well-known scientists and mathematicians. The effects of being exposed to equally bright peers had beneficial effects. One of the side effects of the national training program was to alert the Olympians to a select number of colleges and universities where their talents could be optimally developed. It is our contention that this experience was somewhat responsible for so many of the Olympians enrolling in Harvard, Princeton, MIT and U.C. Berkeley.

#### *Rewarding Accomplishment*

The Olympiad studies underscore the need to identify and develop those with most talent. But in America these needs clash with equity issues (Tannenbaum, 1997). Consequently, gifted and accomplished adolescents often go unrecognized and unrewarded for their efforts. Most of the federal supplemental funding of schools, for example, supports programs for disabled, limited-English speaking, and poor children. Within the past decade, new privately funded programs have arisen to support students of higher abilities and reward them for their effort. The National Alliance for Excellence, for example, gives strictly merit-based university scholarships for near perfect scores on matriculation examinations, the completion of university work in secondary school, and related criteria.

Some psychologists and other experts believe that even more immediate monetary rewards would have bigger effects in encouraging adolescents to put forth greater effort on advanced academic study. Walberg

(1998) recently evaluated apparently the largest program of its kind—the Dallas, Texas-based O'Donnell Foundation's Incentive Program.

The Foundation agreed to pay teachers \$2,500 to take a course on how to teach Advanced Placement (AP) university-level courses and \$100 for each of their students who passed. The students also received \$100 for each AP exam they passed in English, calculus, statistics, computer science, biology, chemistry, and physics, plus a reimbursement for the cost of taking the exam.

In the nine participating Dallas schools, sharply increasing numbers of boys and girls of all major ethnic groups took and passed the AP exams. The number rose more than twelve-fold from 41 the year before the program began to 521 when it ended in 1994–95. After terminating, the program continued to have carry-over effects: in the 1996–97 school year, two years after the program ended, 442 students passed, about eleven times more than the number in the year before the program began.

Though these numbers speak for themselves, interviews with students, teachers, and college admission officers revealed high regard for the Incentive Program. They felt that even students who failed AP exams learned better study habits and the importance of hard work to meet high standards.

In addition, the program had other benefits: students could take more advanced courses in college. Those that passed a sufficient number of AP courses could graduate from college early, which saves their families tuition and tax payers subsidies. Those who passed AP courses also had a better chance for merit scholarships and entry into selective colleges.

The Incentive Program suggests that, at least in the U.S., incentivized standards work in schools as they do in many spheres of life. The lack of incentives in school seems an important reason why American students find academics so boring and sports so exciting. It may also account for the poor showing of typical U.S. students on international comparisons of achievement.

### Conclusions

The data presented above supplies answers to the questions we asked earlier in this chapter: Do the Olympiad competitions serve the national purpose? Do the academic Olympians make important contributions? Do they fulfill their high potential? When the contributions are summed, including the number of doctorate degrees earned, the number of Olympians working as professors (many in technically needed areas), the number of scientists (some in sensitive and needed areas), the 2,921 publications produced, the number working in the computer industry, including several who have founded or managed software companies, and the Olympians working on Wall Street, we must conclude that the Olympians serve the

national interest. They do make important contributions and a number of them fulfill their high potential. Overall, the quality of their contributions outweighs their small numerical numbers. Many of the Olympians are working in leadership positions that magnify their influence.

It must also be remembered that many of these contributions listed above are limited to the oldest Olympiad cohort (72 individuals between the ages of 30–42). These Olympians are in the prime of their careers and can be expected to make many more contributions over the next 20 or 30 years. Furthermore, the younger cohorts can also be expected to assemble a long list of their own contributions.

Having evaluated three competitions, what inferences can be made about the other American competitions? Do they serve the national interest? It is reasonable to infer that the Intel Talent Searches, the JSHS competitions, the SMPY programs, the Science Fairs, and the National Merit Exams all funnel talented students into the United States' science and engineering pipeline. Perhaps this is one of the secrets of America's uncanny ways of developing talent. Campbell (1985, 1992) studied the impact of the Intel Talent Searches on the participants and found that in order to succeed in this competition the students needed to develop the following skills, attitudes, and orientations: learn to manage time; develop library skills needed to conduct technical searches; learn how to read scientific and other advanced material; develop the organization skills to manage a research project; and finally develop the discipline needed to conduct scholarly research studies or to learn how to study for challenging examinations. These enhanced skills not only help the student do well in the contests but can also be applied in future schooling or later in their careers. Even if participants do not win the contest, these newly developed skills will prove very useful. In this sense there may be no 'losers' in a competition where the participants learn things that they can use to enhance their development.

There are some international implications from these analyses. The cost of most of the American competitions is surprisingly low. For example, participation in the Math Olympiad program costs the school only \$15.00 (U.S.) and 75 cents per pupil. The costs for the science fairs, the Intel Talent Search, the JSHS regionals and national, and the National Merit Exams are paid by companies, foundations, or by the government. For the most part students competing in these contests use resources outside the schools. Campbell (1985) found that individual teachers in exemplary schools negotiated lab space for their gifted students in universities or research labs nearby. There was no need to improve or upgrade facilities or computers at the schools.

Therefore, many of these competitions are cost-effective, inexpensive ways to develop talent. Any extra

expenses, including transportation costs, are willingly met by the parents. Consequently, we believe that competitions should be much more widely used internationally. Third world developing countries with limited financial resources for education should develop a wide range of competitions to nurture the indigenous talent that exists in these countries.

# Evaluation as a Critical Component of Program Development and Implementation

Carolyn M. Callahan<sup>1</sup>

## Introduction

The ways in which gifted and talented students are educated continues to be criticized at the local, state and national levels. On the one hand, parents of these students and some educators raise concerns about the lack of services and/or the quality of services that are offered. On the other hand, critical educators question the degree to which such services are really a means for parents of certain students to create a private school education within the public school or a way to create 'exclusively defined' sub-populations, or even whether gifted programs are created for political rather than educational reasons (e.g. Borland, 1997; Sapon-Shevin, 1987, p. 40). Underlying these criticisms lie claims that there is insufficient evidence that the offerings under the umbrella of gifted education really benefit the students to whom they are offered. The second basis of criticism is the claim that educators have not demonstrated that other students in the schools would not have benefited equally well from the offerings. Finally, critics assert that the program offerings are not based on documented needs of the identified populations (Sapon-Shevin, 1987, 1994).

One reason why the criticisms persist is that school personnel have failed to conduct evaluations that provide the evidence that counters those arguments. It is rare for a school division to evaluate and it is even rarer to find evaluations that document the processes or outcomes of their services to gifted students in ways that confirm that the needs of gifted students are being met through provisions not possible within the framework of the general education program (Hunsaker & Callahan, 1993). There is little documentation that the curriculum is sufficiently challenging and provides a depth and complexity of learning that could only be realized by those students identified as gifted. Finally, there is little evidence that students who are in the program are benefiting from it. Unfortunately, the

program evaluation processes that could provide this data or other valuable data for maximizing the educational value of services offered by gifted programs is too often an afterthought—if even given any thought at all. Or, as Southern suggests, evaluations that are conducted tend to “focus on the wrong questions, oversimplify results or are so tightly constrained that the real goals and objectives are overlooked” (1992, p. 103).

While the need to document program outcomes is one important reason why a school division might engage in program evaluation, the usefulness of evaluation when appropriately executed extends well beyond documentation of outcomes to many other domains that may serve to improve services to gifted student. Among other purposes served by program evaluation are documenting the need for a program, justifying a particular program approach, documenting feasibility of selected program approaches, documenting implementation, and generating information about program strengths and weaknesses that can be used for program revision decisions (Callahan & Caldwell, 1995). These purposes are either well served or neglected depending on the role the evaluator assumes and the orientation of program personnel toward the process.

## The Role of the Evaluator and the Evaluation Process in Light of Evolving Conceptions of Program and Service Delivery Models in Gifted Education

In many school districts there has traditionally been one model for the program for gifted students. In this paradigm, a service delivery model (e.g. pull-out, special school, full-time classes for the gifted) and/or a curriculum model (Kaplan's Matrix) are selected by the school division and then the students who 'fit' the model are assigned to receive instruction within the limits of those models. In these school divisions, the evaluator needs to consider at least two fundamental questions. First, is there a match between the models selected and the students selected for the program?

<sup>1</sup> University of Virginia, Charlottesville, Virginia, USA.  
E-mail: cmc@virginia.edu

That is, is the model meeting the students' educational needs and are the goals of the model appropriate for the population selected? A second set of evaluation questions revolve around the degree to which one service delivery option or curricular approach is appropriate for *all* gifted students. Are there gifted students who are *not* identified and/or served appropriately by the given model? For example, do the identification procedures limit the selection of children to a narrow band of high IQ/high achieving children? Or is a child with extraordinary achievement and/or potential for mathematics achievement being well served in a program which once a week gives him opportunities for enrichment in social studies topics?

This second question suggests a more eclectic approach—one that focuses on evaluating services rather than 'a' program. It also reflects a growing exhortation among educators of all special populations, that services for exceptional children be matched to the learner, rather than finding learners who fit the programs (e.g. Tomlinson, 1995). At this point it is critical that the evaluator and the client are in agreement that the evaluation may go beyond judging the current program model and make judgements about the program relative to the state of the art in gifted education. Sharing of standards and criteria to be used for judging 'state of the art' is critical for ensuring that the program and general school personnel value the same criteria as the evaluator. To collect data according to standards not acceptable to the stakeholders will be a waste of time and energy (see later discussion of Evaluation Utility for further information on sources of such standards).

### The Program Evaluation Standards

Standards for the quality of gifted programs provide important benchmarks for consideration in the process of collecting information relative to the efficiency and effectiveness of programming efforts. Equally important in the evaluation process is adherence to the evaluation standards of the Joint Committee on Standards for Educational Evaluation (1994). These standards are organized into four categories representing the four important attributes of quality evaluation (utility, feasibility, accuracy and propriety). The particular standards provide guidelines useful in the design, implementation and assessment of evaluations of gifted programs that will be fair, valid, useful and ethical.

### Evaluation Utilization

A well-conceived and well-implemented evaluation process can provide critical information that can be utilized by two sets of clientele. The first and foremost is the group of stakeholders who are in the position to make decisions about the program under examination. A second audience for evaluations is the group of educators outside the program who will benefit in the

design and implementation of other gifted programs from the data collected. However, neither of these audiences is well served if the process and report (or reports) do not have those characteristics that lead to both attention to and appropriate response to the information and recommendations presented.

Whatever the reasons for undertaking an evaluation, the persons who initiate and carry out the process do so with some expectation that the findings will actually be used. However, the application of the evaluation findings and recommendations in making commendable decisions and bringing about improvement in the services offered to gifted students has been documented to be dependent on many factors (Tomlinson, Bland & Moon, 1993). Some of these factors are outside of the control of the evaluator; other factors can at least be somewhat under the control of the evaluator. Whether the factors are those that can be controlled or not, consideration of their impact will provide cautions and guidance in improving the effectiveness of the process and sometimes even prevent the expenditure of precious resources in a fruitless endeavor (Shadish, Cook & Leviton, 1991).

Researchers in the field of evaluation in general and from the field of gifted education have identified many factors in the evaluation context which are out of the evaluator's control (e.g. Weiss, 1983). For example, economic factors within the school or school division influence the likelihood of the implementation of the recommendations of the evaluation (Patton, 1988). If the evaluator recommends fundamental changes in the program that are clearly outside the financial capabilities of the institution, the report is liable to be shelved with little consideration of the findings. Or decision-makers may focus on the less costly, but probably ineffectual, recommendations which have little probability of having a significant impact on children's learning but will give the appearance of having 'done something'.

Of course, there are times when the fiscal decisions rest on political values and concerns (Patton, 1988; Shadish, Cook & Leviton, 1991). If decision-makers are not committed to a program or to improving services to gifted students, the prospect of a major infusion of funds to bring about change is very unlikely, even if the school division financially capable of appropriating monies for suggested change. The evaluator should also be aware of a school division's basic philosophies about general education, giftedness and/or gifted services before undertaking an evaluation. To make recommendations for a full-time school for the gifted in a school division that has just taken an emphatic public stance supporting the inclusion of children with handicapping conditions will probably make all other recommendations suspect. Or to recommend that a gifted program be extended to include children with talents in the arts in a school division with no art teachers is folly.

### The Utility Standards

The Utility Standards of the Joint Committee were designed to guide evaluations so they would be 'informative, timely and influential'—the critical variables determined by the Committee to influence utility (p. 8). The Joint Committee (1994) and Tomlinson, Bland & Moon (1993) have provided a summary of the research supporting the eight specific standards: Stakeholder Identification, Evaluator Credibility, Information Scope and Sequence, Values Identification, Report Clarity, Report Timeliness and Dissemination, and Evaluation Impact.

#### Stakeholder Identification

To meet this standard, the evaluator would identify all persons involved in or affected by the gifted program, so that their informational needs can be addressed and so that no critical information is either missed or ignored. Reineke (1991) concludes that evaluation experts discussing evaluation utility concur that involving stakeholders early, continuously, actively, and within a clearly focused structure leads to the most efficient and effective identification of concerns. To be sure all stakeholder are involved in an evaluation of gifted services, an evaluator should consider, for example, the stakeholder defined as the parent of a child not identified and served as part of the gifted program services. Further, an evaluator should always make special efforts to ascertain whether there are less powerful groups or individuals who may not be included in initial lists of informants (for example, representatives of the full range of socio-economic groups; racial, cultural, or language minority groups). In the sensitive case of gifted services these steps are of particular concern due to the charges of elitism that are already likely aimed at services. Unfortunately, a study of evaluation reports on gifted programs revealed that the majority failed to address this standard adequately. The questions, data collection and recommendations were directed primarily toward administrator concerns (Hunsaker & Callahan, 1993). One systematic procedure for gathering stakeholder input was prescribed by Renzulli (1975). In this process of 'Front End Analysis', key informants are asked to identify their greatest concerns through an open-ended survey, interviews, and focus groups. Data from these procedures are subject to content analysis. A more statistical approach is offered by Miller, Klein & Troutt (1985) and involves prior specification of goals and sub-goals, which are then submitted to focus groups for weighting.

A critical second step in appropriately addressing the stakeholder concerns is to inform stakeholders that not all interests can be equally addressed and then to choose the issues which reflect important and answerable questions. In a gifted program one might find that an individual parent may raise concerns unique to his/her child, but not relevant to program issues.

#### Evaluator Credibility

The second standard, Evaluator Credibility, calls for evaluators to be appropriately trained in technical and substantive knowledge and to exhibit trustworthiness and integrity as well as public relations skills. The Committee suggests that the wide range of skills and knowledge called for are often not present in one individual necessitating the creation of a team of evaluators. In gifted education, with the range of loyalties to definitions, philosophies, models and practices within the field, it is critical that the evaluator be well-versed in these before attempting an evaluation. Multiple perspectives from a team allows for the data to be interpreted across a variety of perspectives and provides balance to interpretation.

#### Information Scope and Selection

The third standard flows naturally from the first and requires the evaluator to collect data relevant to the issues that have been identified by stakeholders (within realistic expectations and the budget for evaluation). But it requires that in the evaluation process, evaluators must collect information from multiple sources and across "important variables (e.g. effectiveness, harmful side effects, costs, responses to learner needs, meaningfulness of assumptions and values underlying the program) whether or not the stakeholders ask for such information" (p. 39). It is this standard where most evaluations of gifted programs are lacking (Hunsaker & Callahan, 1993). Reviewing the literature in the field of evaluation of gifted programs reveals evaluation studies that fail to address little more than participant (parent and/or student) perceptions of services received. Accountability, in the form of examination of classroom instruction or outcome variables is still lacking and the literature continues to call for greater accountability in these domains (Southern, 1992; Gallagher, 1998). Often the standard is not addressed fully because the evaluators rely on the simplest strategy for gathering data, the survey, (Hunsaker & Callahan, 1993) which will provide only limited information about programs.

#### Values Identification

Values Identification is a standard that has obviously grown out of the increased recognition that judgements are made relative to some "pertinent and defensible idea of what has merit and what does not" (p. 43). Two useful, and somewhat parallel, guides offering criteria potential criteria for gifted program evaluation are the Key Features components identified by experts in the field and reported and described by Renzulli (1973) and the *Gifted Education Programming Criteria* (National Association for Gifted Children (1998)). The Key Features include philosophy and definition of giftedness, identification, staff selection and training, curriculum, program organization and operation of the program. The *Gifted Education Programming Criteria*

provide statements describing both requisite and exemplary attributes across the domains of curriculum and instruction, program administration and management, program design, program evaluation, socio-emotional guidance and counseling, professional development, and student identification. Examples from the standards are provided in Table 1.

**Report Clarity/Report Timeliness and Dissemination**

As one might expect, the format of an evaluation report (regardless of whether it is an oral report, series of written memos, or a lengthy document) and its timeliness are key in leading to understanding and implementation of recommendations. The report(s) should be characterized by full descriptions of the purposes, the context, the process, the conclusions and recommendations. Making the report(s) as brief, direct and simple as possible without sacrificing necessary detail and precision will serve the clients more effectively than complex and technical documentation. An executive summary helps direct the consumer to the most salient and important conclusions and recommendations. Having the client and select representatives of the intended audiences for the report read and comment on a draft prior to final distribution is a useful strategy for ensuring clarity to various audiences.

**Evaluation Impact**

Finally, the standards urge evaluators to assume responsibility for helping stakeholders use the evaluation findings, but to avoid taking on the role of the client. The urge to create (or re-create) the ideal gifted program for a school district must be avoided. Not only do evaluators not have the power or authority to direct program reconstruction, if they assume a direct role in that process, the client and stakeholders are deprived of the respect they deserve and need to maintain in the institution.

*Table 1. Sample Gifted Education Programming Criteria.*

Guiding Principle	Minimum Standard	Exemplary Standard
Learning opportunities for gifted learners must consist of a continuum of differentiated curricular options, instructional approaches, and resource materials.	Diverse and appropriate learning experiences must consist of a variety of curricular options, instructional strategies, and materials. Flexible instructional arrangements (e.g. special classes, seminars, resource rooms, mentorships, independent study, and research projects (1) must exist.	Appropriate service options for each student to work at assessed level(s) and advanced rates of learning should exist. Differentiated educational program curricula for students pre-K-12 should be modified to provide learning experiences matched to students' interests, readiness, and learning style.
Gifted education must be adequately funded.	Gifted education funding should be equitable compared to the funding of other local programming.	Gifted education programming must receive funding consistent with the program goals and sufficient to adequately meet them.

**Effects of Adhering to the Utility Standards**

Tomlinson, Bland, Moon & Callahan (1994) examined the utilization standards relative to the impact that adhering to the standards had on producing quality evaluation reports and the ultimate use of evaluation results to change programs. Hunsaker & Callahan (1993) provided a conceptual framework for the study by describing the current state of practice in evaluating programs for the gifted and identifying factors associated with 'strong' and 'weak' evaluation designs and practices in gifted programs. Hunsaker and Callahan described as weaker those reports which:

- (1) were disseminated solely to district administrators as opposed to broader stakeholder audiences,
- (2) failed to include recommendations for action; and
- (3) lacked apparent mechanisms for translating findings into action.

Reports categorized as stronger were disseminated more broadly, included recommendations for action, and outlined mechanisms for translating findings into positive program change. Tomlinson, et al. then interviewed the stakeholders of programs, which had received the 'stronger' and 'weaker' reports to determine the degree to which reports from stronger and weaker districts were utilized for positive program change. For purposes of this study change was defined as use of formative and/or summative evaluation information that affect a program for gifted learners in at least one of three ways: (1) altering ways in which program participants, evaluation audiences and/or decision-makers thought about the program; (2) changing the decision-making process and/or decisions made by stakeholders in the program; or (3) invoking some action regarding implementation of the program. One unexpected, but very important finding, was that districts using *any* evaluation process at all used the information gathered through the process to bring about some level of change. The clear goals of the evaluation process in the stronger districts led to more specific,

Table 2. The Nature of Changes in Districts Using Weak and Strong Evaluation Practices.

Weak Evaluation Practices	Strong Evaluation Practices
Evaluation goals not stated, therefore changes not tied to goals, 'random'	Goals are focused on specific program elements, 'systematic'
Nature of services was changed to better meet the needs of students	Nature of services was changed to better meet the needs of students
Additional program resources secured staff development; provided to clarify misconceptions	Additional staff development provided to assist with meeting the needs of students and the parameters of the new program initiatives
Schedules and other program elements were changed to assist in general instruction in the school	Additional resources provided by the school board to enact those changes
Information on the program provided to parents	Staff development implemented to prepare for change in the services provided

Note: From 'Case Studies of Evaluation Utilization in Gifted Education', by Carol Tomlinson, Lori Bland, Tonya Moon & Carolyn Callahan, 1994, *Evaluation Practice*, 15, p. 160.

targeted recommendations and subsequent program changes. Table 2 outlines the commonalities and distinctions between the nature of changes resulting from the two categories of reports.

Two key factors correlated with use of evaluation findings in districts studied—will and skill. It appears that the will to evaluate on the part of some key personnel in a district, supplemented with systematic procedures and resources for doing so, results in generation of evaluation findings and translation of those findings into program change. This will to evaluate existed in both the weaker and stronger districts studied. The second factor, skill in evaluation and related processes, appeared to be the demarcation between the two categories of districts and affects the robustness of program change stemming from evaluation findings. Utilization appeared more likely and changes from the findings more potent and systemic in direct relationship to the following conditions:

- (1) Evaluation of programs for the gifted was a part of a district-wide policy requiring routine evaluation for all program areas.
- (2) Systematic written plans were in place delineating steps and procedures for ensuring implementation of findings.
- (3) Multiple stakeholders were consistently involved in planning, monitoring, and reviewing the evaluation process and its findings.
- (4) Stakeholders played an active role in planning for and advocating before policy makers for program change based on evaluation findings.
- (5) Key program personnel were knowledgeable about gifted education, evaluation, the political processes in their districts and the interconnectedness of the three. In instances where program administrators with expertise in both gifted education and evaluation were not available, leaders invoked volunteer

steering committee members with such expertise. (Tomlinson et al., 1994, p. 165.)

Callahan, Tomlinson, Hunsaker, Bland & Moon (1995) used the results of the reviews of the literature and these utility studies to create a set of fundamental guidelines for the evaluation of gifted programs (see Table 3) and these guidelines have been given further explication by Tomlinson & Callahan (1993, 1994).

#### *Feasibility Standards*

One delicate balance that is often difficult to achieve in evaluating gifted programs is the one between the ideal plan and the affordable plan. While in theory the evaluator would like to conduct comprehensive and in-depth evaluations across a myriad of questions identified by stakeholders, gifted programs are not likely to have unlimited, excess, and uncommitted funds to expand on evaluation. The feasibility standards were designed to help the program staff and evaluators design evaluations that are "realistic, prudent, diplomatic and frugal" (p. 63).

#### *Practical Procedures*

Maximizing practicality and minimizing disruption are the core of this first feasibility standard. The standard cautions evaluators to attend to the steps in implementation that include choice of data sources; instruments; administration procedures; data and information collection, storage and retrieval. In particular, it would suggest that evaluators of gifted programs should ensure that appropriate instruments are available or can be developed to assess the evaluation questions. Cautions abound in the literature on gifted program evaluation regarding the validity of using traditional standardized assessments as outcome measures (e.g. Renzulli, 1975; Callahan, 1983; Gallagher, 1985; Callahan & Caldwell, 1986). While performance and product rating scales (e.g. Schack, 1994), guides

Table 3. Principles Derived from Evaluation Utilization Study

- Make evaluation part of planning from the earliest stages of program development or a part of planning when program changes are proposed.
  - \* A program which anticipates and builds in systematic processes and timelines is more likely to yield data which are useful to varied stakeholders and is more likely to be aimed at positive, focused program change.
  - \* A commitment to evaluation by the gifted education staff is essential, but needs to be accompanied by a clear division-wide expectation that all program areas will be evaluated regularly and appropriately. Without a commitment that evaluation should result in program change on the part of the people in positions of power and influence, little attention is likely to be given to evaluation findings.
- Develop clear program descriptions and goals.
  - \* These should provide a roadmap for evaluation as you seek to determine whether the program is meeting specific goals and is functioning as described. Be sure that goals are specific, focused and clear, and that descriptions are accurate.
- Provided adequate funding for evaluations and time for evaluation procedures to be executed fully,
  - \* It is unlikely that a broadly useful evaluation will be conducted in the absence of funding for preparation of evaluation materials, support personnel, data processing, etc. A well-planned evaluation will require ample time in order to involve key stakeholders and to assess varied aspects of program function.
- Prepare staff for conducting and analyzing the results of the evaluation.
  - \* In evaluating programs for the gifted, it is important that persons knowledgeable of both evaluation and gifted education play lead roles throughout the evaluation. It is likely that in many school divisions that key personnel will need meaningful training in one or both areas.
- Clearly identify all audiences who have an interest in or need for evaluation results and involve them in the full evaluation process. Involvement of multiple stakeholders throughout the process gives more people a sense of ownership of both the program and its outcomes, and yields more advocates for positive program change stemming from evaluation findings. Be sure to include relevant policy makers in the group of stakeholders.
- Ask questions which are well focused to provide information about the goals, structures and activities of the program being evaluated – questions which will aid in making significant program improvements
- Use multiple data sources in order to understand the values and perspectives of various groups of stakeholders.
  - \* Members of school boards, building and central office administrators, identified students, regular classroom teachers, g/t program staff, counselors, and many others will be able to give interesting insights into program functioning.
- Develop evaluation designs that address complex issues of measurement in programs for the gifted.
  - \* Assess both process and product outcomes.
  - \* Quantitative designs may be more effective in looking at product outcomes and qualitative designs may be more effective in looking at process outcomes, but the most important criteria in selecting an approach is to match the evaluation question with the most appropriate data collection strategy.
  - \* Avoid reliance on traditional standardized measures that offer little promise of reflecting academic growth in learners (consider instead options such as authentic performance and product assessments).
- Use a variety of data gathering methods designed to reflect the unique structure and goals of programs for gifted learners (e.g. out of level testing, portfolio assessment, product rating with common criteria and demonstrated inter-rater reliability, qualitative studies which describe unique settings, interviews, surveys, observation checklists, etc.)
- In evaluation reports describe fully procedures for data collection and interpretation so that audiences understand processes which were followed and conclusions which were drawn
- Disseminate to all appropriate audiences reports that are timely and designed to encourage follow-through in translating findings into action. Develop a specific plan for turning findings into positive program growth as an essential part of each evaluation, including roles which various program personnel, evaluators and stakeholders play in that plan.

for exemplary high level rubrics (Wiggins, 1996), and non-traditional assessments have been recommended and developed (e.g. Treffinger, 1994; Callahan, Covert, Aylesworth & Vanco, 1976), the expense and reliability and validity issues surrounding those assessment tools should be examined to ensure that there are sufficient resources and adequately trained personnel to develop, validate and score such tools (Baker, O'Neil, & Linn (1994). In evaluating programs for gifted children in schools with high mobility stemming from poverty or other factors, the evaluator who seeks to track children longitudinally must take care that an adequate sample size is selected to ensure data analysis will be meaningful given attrition. And whenever possible, assessments should be piloted to ensure clarity and

reasonable assessment time requirements. This includes testing and survey instruments. Because the use of non-traditional instruments often requires special testing or assessment procedures, there is always potential for disruption and the intrusion on limited instructional time. In gifted programs where students are served in special pullout arrangements such assessment is particularly disruptive. All efforts should be made to minimize lost instructional time and minimize disruption of normal routine.

#### Political Viability

If the guidelines for including all critical stakeholders suggested by the utility standards have been followed, then the first step has been taken to ensure that this

standard has been adhered to. However, there are always potential political pitfalls. In conducting an evaluation of gifted programs, the evaluator should be aware of the many potential political pressure groups that may be using the evaluation process to advance an agenda. An evaluation may be a veiled attempt to do away with a particular program model, or to change the funding patterns in the program, or even to change staffing. It is critical that all stakeholders be given the opportunity to voice any potential political issues and that during the process of evaluation to give a complete and balanced opportunity for all groups to have input into the data collection process. It is also critical that agreements be made at the beginning of the process regarding the conditions surrounding data collection—particularly assuring access to all needed data and assurances of appropriate control over editing and dissemination of the report. During the process of data collection evaluators should take every possible step to ensure that there is neither appearance of nor actual bias in giving opportunities to one group over another in providing data. In addition to careful selection of samples for surveys, interviews, observations, etc., one practice to avoid such bias is the scheduling of at least one open forum that is announced publicly and open to any interested parties.

#### Cost Effectiveness

This standard is seemingly self-explanatory; however, the most important concerns relative to gifted programs is an assurance that there is a proper balance between the human and financial costs in terms of student and staff time, financial costs and the potential benefits to the client. Appropriate attention to this standard requires careful budgeting and planning, seeking the most cost efficient means of data collection, and ensuring that funds are in place to carry out the full evaluation before the process is begun. Not all products must be assessed, not all parents must be surveyed, and not all children must be assessed on all instruments.

#### Propriety Standards

The propriety standards ensure that the legal and ethical standards of evaluations are met and that the welfare of those involved in the evaluation is safeguarded. These standards serve the rights of the client and the various stakeholders and other sources of information.

#### Service Orientation

This standard reflects the broader interests of evaluators in ensuring that the program examined addresses educational goals that are important, that learner development is addressed, promised services are delivered, and ineffective and harmful programs are removed. The standard urges evaluators to design the evaluations that promote excellence. The question “Is this gifted program really better than no program at

all?” is often raised in program evaluation. This standard would suggest that the question, “Is this an excellent program?” would be a better focus of the evaluation. Further, it mandates that evaluations look at features most likely to positively or negatively affect participants. Hence, examining after-school program options while giving only cursory attention to the core school day program for gifted students illustrates inappropriate application of the standard. The NAGC program standards clearly call for a program that is integrated with the school day. After-school programs are not as likely to affect the students in positive ways. Attention to after-school programs is warranted if there is a sense that undue resources committed to those programs may actually be detracting from a core program of the school.

#### Formal Agreements

The recommendations for formal agreements include statements of purposes, identification of stakeholders and evaluation questions, deliverables, data collection procedures, analysis procedures, management plan, reporting plans, commitments of services, materials, personnel, timeline, budget and payment schedule (if external), provision for review and modification of the agreement.

#### Rights of Human Subjects and Human Interactions

Any evaluation of children and programs with limited enrollment and a small faculty such as gifted programs are subject to very special problems with privacy protection. Evaluators not only have to ensure that everyone is aware of the process and has full and complete understanding of the process, they must also take steps to ensure that rights of participants are protected and confidentiality is guaranteed. When anonymity is promised, every effort should be made to preserve that promise. Descriptions of classrooms or reports of classroom activities in gifted special classes will often breach that anonymity.

#### Complete and Fair Assessment, Conflict of Interest and Disclosure of Findings

When engaged in gifted program evaluation as an educator who supports gifted services, it is easy to allow oneself to become attached to a person or persons in the school division who share beliefs, philosophy or even just commitment to the population to be served. When this occurs, it is difficult, but critical that the evaluator take precautions to report on both strengths and weaknesses as revealed by the data and not commit the error of “manipulating the reporting of strengths and weaknesses to please partisan individuals or interest groups or allowing deletion from the report of weaknesses that might prove embarrassing or to further or protect the evaluator’s personal interests or biases” (p. 106). The

outside evaluator who ascribes to a particular model (or worse, is the developer of a curricular or program model of the school) is particularly susceptible to such issues and should take the extra step to have data reviewed by those with differing perspectives to screen for bias in interpretation.

Full disclosure requires the open and candid sharing of reports and information, except of course, when the disclosure of particulars would in some way violate assurances of anonymity, confidentiality or any other breach of ethics or would embarrass or violate human rights considerations. The credibility of the evaluation report rests on confidence that the conclusions drawn are warranted. Any potential biases that influence decisions or equivocal conclusions should be clearly noted. Evaluators with any financial interest in the success of the program or the reporting of findings (positive reports may lead to positive recommendations for further contracts; positive evaluations of models proposed by the evaluator may lead to further consultation) need to disclose those interests and publicly explicate the procedures that will be used to bring more independent judgements to the data analysis and interpretation. Full disclosure of procedures, data and reports will also increase credibility.

*Accuracy Standards*

Most of the accuracy standards parallel those one finds guiding sound research studies so will not be described in full in this text. They include program documentation, context analysis, described purposes and procedures, defensible information sources, valid information, reliable information, systematic information, appropriate analysis of qualitative information, appropriate analysis of quantitative information, justified conclusions, and impartial reporting.

*Current Evaluation Practices*

The reporting of evaluation practice in the literature is very limited. This is likely due to three factors. First, evaluation is not research and not subject to the same constraints to ensure generalizability and/or attribution of cause. Second, in many cases, the evaluation report is the property of the school division and the officials of school divisions are not apt to feel comfortable with publication of results which may point to serious flaws in the implementation of their gifted programs. Finally, the evaluation report that meets all of the technical requirements that have specified by the standards is likely to be too lengthy for the typical journal publication.

*Measurement of Student Outcomes*

Experts in gifted education and assessment continue to call for the measurement of student outcomes in gifted program evaluation. Gallagher (1998) outlines the domains of mastery of a body of knowledge, mastery of new skills and competencies such as designing and executing a scientific experiment, attitudes, motivation, products, process, problem finding and problem solving as worthy of the expenditure of time and effort in program evaluation. Treffinger (1994) has created a taxonomy of levels of creative learning and production and identified assessment or evaluation approaches to match each level (Table 4).

The limited literature that is available documenting program evaluation efforts in gifted education reflects continued reliance almost entirely on formative and process data with little attention to the measurement of student outcomes except student or parent satisfaction with the program and/or teacher report of accomplishment through surveys, post hoc interviews, or incidental observation of group discussions (e.g. Dor-

Table 4. Assessment and Evaluation of the Creative Learning Model.

Assessment or Evaluation Approach	Level 1: Basic Tools	Level 2: Learn/Practice Process	Level 3 Real Problems
Tests	Useful to assess level of proficiency or growth in basic areas (e.g. creative or critical thinking).	Expansion to multiple choice or written responses to assess process skills may be useful.	Not recommended.
Performance Tasks	Tasks of brief scope and duration can yield information relating to skill or proficiency in basic tools.	Wide variety of tasks can be used to provide realistic assessment of performance (e.g. cases, scenarios, practice problems)	Extended tasks or group projects can contribute to assessing and documenting proficiency.
Portfolio	Might include documentation or applications of specific tools or strategies in particular contexts.	Might include documentation of involvement in competitions, contests, or other structured programs.	Includes a variety of ways to document success and experience in dealing with real problems.

Note: From 'Productive Thinking: Toward Authentic Instruction and Assessment', by Donald J. Treffinger, 1994, *Journal of Secondary Gifted Education*, 6, 30-37.

sal & Wages, 1993; Forster, 1994; Taplin, 1996; Davalos & Haensly, 1997; Frasier, Lee & Winstead, 1997).

Some exceptions have included measurement of changes in self-concept using the Self-Description Questionnaire (SDQIII) (e.g. Clark & Dixon, 1997) and achievement using the ETS Cooperative Mathematics Test in Calculus (McBride & Lewis, 1993). But these studies measured pre- and post-test score differences with no control or comparison groups or even comparison to norms of the tests. Even if significant differences were found across time, change could not be attributed to the program offered.

Although not carried out as an evaluation study of a particular district's gifted program, the curricular evaluation done by Sternberg, Ferrari, Clinkenbeard & Grigorenko (1996) provides a model of using an outcome measure structured to match the curricular goals of a program and also designing an evaluation where outcomes can be clearly attributed to the intervention. This intervention, offered to a particular, specifically defined group of gifted students was evaluated only by outcome variables. By structuring the program so that all students received services, but they receive clearly delineated curricular interventions, the authors were able to document those curricular modifications most effective with particular students.

Affective outcomes relating to peer social competence relations were examined by comparing sociometric assessments, evaluations of friendship relationships, and peer nominations as aggressors and as victims of aggression in an evaluation of a pull-out program by Cohen, Duncan & Cohen (1994). In this case, the measures with program students were compared with students not served by the program.

Case study data was used to supplement questionnaire data collected by Moon, Feldhusen & Dillon (1994). While this approach provided stronger perceptual data due to the in-depth data collection process, the retrospective and perceptual nature of the reflections makes attribution of outcomes less justifiable than would be achieved by measuring student change more directly.

Looking at incidental, non-intended outcomes, has been the focus of Marsh's evaluations of the effects being placed in gifted classrooms on the self-concept of gifted students (e.g. Marsh, Chessor, Craven & Roche, 1995). While Marsh et al., like Sternberg et al. (1996), have presented research results, their studies suggest measures and assessment strategies that might be adopted for evaluation paradigms. These paradigms, however, require planning for data collection and the assignment of students in ways that are not normally considered in program development, bringing to the forefront once again the notion that gifted program evaluation will be most effective if planned in conjunction with program planning or revision.

### **Inhibitors to Quality Program Evaluation**

Given the general standards of program evaluation and the specific guidance offered by so many, why do we still fail to see extensive quality program evaluation? Moon's survey of program administrators (1996) provides us some insights. Not surprisingly, lack of time, lack of knowledge of qualitative analysis, lack of knowledge of program evaluation, lack of knowledge of statistics, and lack of knowledge of survey design were the biggest inhibitors to internal evaluation efforts. Surprisingly, lack of funds was rated quite low, raising questions about the lack of evidence in the literature of use of external evaluators.

### **Conclusions**

The last twenty years has brought about the development of a professional field of evaluation with clearly established guidelines for educational program evaluation. Parallel translation of the guidelines and studies of evaluation utility in the field of gifted education have provided educators with a sufficient number of strategies, recommendations for evaluation procedures, models, and exhortations to evaluate more systematically and comprehensively. Yet, the literature suggests that these evaluations are still not occurring. The identification of reasons for the lack of internal evaluation gives us some insight into the lack of such models, but we still have no reasons to explain the lack of involvement of external evaluators. We might speculate on the reasons why. Obviously, there are no mandates for evaluations of gifted programs so the legal requirements will not spur the kind of evaluation that accompanies Title I legislation or drop-out programs, etc. So there is a reliance on the judgement of local school administrators that program evaluation will be worth the time and effort and financial commitment that will be required. The cost of external evaluation may be prohibitive to school divisions with minimal allocation of funds to gifted programs. Program administrators may be threatened by the prospect of evaluations, feeling that their personal competence as administrators may be judged. Or there may be some well-founded fear that the programs are not representative of excellence, fail to challenge the high-end learner or to produce the desired outcomes. Perhaps, evaluation is avoided because it will reveal that the goals of the program are not clearly delineated and the staff feels lacking in an ability to articulate the goals. Or perhaps, more simply, administrators simply have no understanding of the importance of the evaluation process in helping to identify program strengths and weaknesses, program improvement, or in documenting program effects and the importance of examining ways to maximize those effects. We owe it to gifted students to address these issues and provide the data that will enhance the educational opportunities

afforded to them. Program evaluation provides the local schools or state systems that opportunity.

# Cross-Cultural Studies in Gifted Education

Edna Leticia Hernández de Hahn<sup>1</sup>

## Introduction

Although giftedness and talent development are topics that have fascinated humans since ancient times, cross-cultural studies in gifted education are a relatively recent endeavor. The factors that have fostered the emergence of cross-cultural studies in gifted education include the theoretical and methodological developments in cross-cultural psychology, the creation of international competitions in various academic areas, and the serious concern that important differences in academic achievement exist across cultures and that these differences have an impact on other areas of performance.

This chapter examines historical, theoretical and methodological issues related to the development of cross-cultural research in gifted education. The first section explores the meaning of culture and the ways in which it affects giftedness. The second section deals with the methods and research strategies that are used in the field. Also included is a brief history of the methodological approaches used in research on cultural differences. The third section analyzes studies in three major areas of cross-cultural research, namely, cognitive processes, affective issues and academic performance. The final section provides guidelines for future studies in this domain.

## Giftedness and Culture

Since giftedness is a socio-cultural phenomenon and not a quality that can be directly observed and measured (Feldhusen & Heller, 1986), its nature has been the object of much debate and it has been defined in many different ways (e.g. Sternberg, 1986). Although the 'gifted construct' may be similar across cultures (Frasier & Passow, 1994), the way in which abilities and talents are manifested and the procedures that are required to identify gifted individuals in the various cultural groups are different (e.g. Brush, 1971; Baldwin, 1991). Culture also has a direct influence on the type of gifted behaviors that are valued and fostered (e.g. Frasier, Garcia & Passow, 1995). Thus, time and

space factors are determinants of the gifts and talents that any given society nurtures and the way in which it chooses to identify individuals who possess or who are able to develop these qualities. The way giftedness is interpreted depends on the values and world views of each culture.

This emphasis on culture in the field of giftedness has an important implication. Namely, that human abilities are not immutable and that perceived differences in talent and capacity among groups of people (sometimes labeled 'races') are not entirely biologically determined (e.g. Nisbett, 1995). In fact, the term 'human race' has lost its meaning due to the enormous genetic diversity and has simply become a social construct (Cavalli-Sforza, Menozzi & Piazza, 1994).

Throughout history, culture has been the basis for identifying groups of people who differ in some behavioral aspects from other groups due to their ethnicity, national origin, place of residence, or other related factors. Like giftedness, culture has many definitions. In the past, emphasis was placed upon the notion that culture is "a shared way of life of a group of socially interacting people" (Segall, Lonner & Berry, 1998, p. 1104) and that it is transmitted from one generation to the next. More recently, emphasis has been placed upon the fact that culture is not simply an external reality that affects human behavior, but that it is actively created by each person throughout daily interaction with their surroundings (Segall et al., 1988; Shweder & Sullivan, 1993).

As the 19th century drew to a close, a new interest in 'culture' emerged and the empiricist conception of the person, which assumes humans are natural beings that exist materially in the space time continuum, declined (Kashima, 2000). The empiricist conception of the person had its origins in the 18th century Enlightenment Period, when psychology and education attempted to emulate Newtonian physics in the area of research methodology. The successful physical scientist viewed experimentation and causal explanation as fundamental to the process of finding universal truths. As psychologists were compelled to follow the tracks

<sup>1</sup> University of Munich, Germany and Iberoamerican and National University, San Diego, California, USA.

of positivism, culture was regarded as a material process, external to the person, and therefore, not an object of study for psychology. Psychology developed to utilize causal laws to explain human behavior. Kashima argues that the decline of the empirical perspective in the 1970s and 1980s was the logical consequence of the political, economical, historical and technological changes that took place after World War II. In the following years, theorists proposed an interpretive conception of culture. This perspective saw culture as an integral part of a person and stressed human intentions. It also suggested that the socio-cultural context must be examined in order to interpret human behavior. This is the assumption on which all cross-cultural research is based.

Cross-cultural research investigates the differences in behavior among cultures and attempts to interpret these differences. Since ancient times, travelers, missionaries and philosophers have recorded and attempted the interpretation of the differences they observed between cultures. However, it was not until the 19th century that cultural diversity was studied systematically (Klineberg, 1980). Systematic cross-cultural research in gifted education is a recent phenomenon and has focused on studying issues related to cognitive performance, affective factors and academic achievement. The following section discusses topics related to the methods and paradigms utilized in cross-cultural research.

### Methodological Issues in Cross-cultural Research

#### *Research Strategies in Cross-cultural Studies*

Because education is a field of study in which many other sciences converge, educational researchers have traditionally used methods of inquiry that are used in other fields, in particular, psychology, anthropology, sociology and history (e.g. Borg & Gall, 1989; Gay, 1996). These methods may be grouped into two paradigms, the scientific model and the humanistic model (Husen, 1999). The first method models the natural sciences, emphasizing empirical, quantifiable observations and attempts to find causal relationships. These relationships are usually guided by a hypothesis that is drawn from a theoretical framework. The second method is derived from the humanities and focuses on holistic, qualitative information and interpretive approaches. This type of approach is commonly used in exploratory studies. Since the early 1990s, researchers have acknowledged that neither paradigm can answer all the questions posed and that the methods are not mutually exclusive, but rather complement each other (Husen, 1999; Landsheere, 1999).

Not surprisingly, the cross-cultural studies in gifted education have used research methodologies and theoretical approaches that are typically used in cross-cultural psychology and in comparative education. Cross-cultural psychology has not only provided the

field of education with useful knowledge about cultures, but has also helped to develop theoretical perspectives and frameworks that have been useful in cross-cultural research in education (e.g. Harkness & Keefer, 2000). Likewise, comparative education has investigated topics (e.g. international comparisons in academic achievement) and used methodological tools that have attracted the interest of cross-cultural researchers. Given these connections between disciplines, several historical, theoretical, and methodological issues related to cross-cultural psychology and comparative education will be discussed.

Cross-cultural psychology seeks to determine the effects of culture on behavior and psychological development through the use of various types of comparative research (Segall, Lonner & Berry, 1998). The field of cross-cultural psychology emerged shortly after World War II, developed rapidly during the Cold War years, and was institutionalized in the 1960s (Johda & Krewer, 1977). During the early stages of cross-cultural psychology, researchers, like those in other disciplines (e.g. biology, linguistics, sociology and anthropology), focused on the discovery of universal ideas. To achieve this, two tasks had to be completed. First, the current psychological knowledge had to be tested in other cultures. Second, new aspects of various psychological phenomena had to be explored or discovered (Berry & Dasen, 1974). These early stages were characterized by methodological problems that originated in the tendency of the researchers to use Euro-American theoretical frameworks. One of the consequences of this approach was that the instruments developed and validated in one culture were used in another culture. The assumption was that the instrument would be measuring the same constructs. When the flaws of this approach became evident, researchers argued that the existence of psychological universals could only be supported if the psychological phenomena was first explored within each culture (emic research) and then across other cultures (etic research) (Segall et al., 1998).

Berry, Poortinga, Segall & Dasen (1992) identified three theoretical orientations in cross-cultural research: *absolutism*, *relativism* and *universalism*. The *absolutist* orientation takes for granted that all humans exhibit the same basic psychological processes and that culture has little, if any, effect upon their manifestations (etic research). Therefore, instruments validated in one culture may be used indiscriminately in other cultures and evaluative comparisons may be made. The results are then interpreted from an ethnocentric perspective and all views are excluded except those pertaining to the culture in which the researcher is immersed. The second orientation is *cultural relativism*, which neglects the relevance of similarities among different cultural groups and avoids making comparisons, particularly those of an evaluative nature. The last orientation is *universalism*, which most cross-cultural researchers

adhere to. It is also called the integrationist approach (Kim, Park & Park, 2000). Followers of this approach argue that culture produces differences among groups, as well as among individuals within groups. They also believe that processes may only be considered universal after their existence in all cultures has been empirically proved. Although all humans share certain characteristics, their manifestations vary due to cultural differences. In the context of assessment, this implies that only instruments that take these differences into account can accurately measure the underlying processes and that, when interpreting the results, perspectives from the various cultural groups must be considered.

Most of the cross-cultural research conducted in the past concentrated on international work that involved exploring other cultures (Berry & Annis, 1988). These cultures were compared and, after analyzing the results, some dichotomies were created that would aid in the classification of cultures. These dichotomies included individualist vs. collectivist models and Western vs. non-Western societies. Despite clear evidence that the world society is becoming more interconnected, Hermans & Kempen (1998) found that many researchers still use these dichotomies and assume that culture is geographically localized, internally homogenous and externally distinctive. Some researchers continue to disregard the fact that cultures are increasingly more complex and less stable, coherent and independent. With new technologies and improved means of transportation, the process of globalization is fostering the interaction between people of all cultural backgrounds. The connections between societies exist in all areas: ecological, demographical, economical and political (Wolf, 1994). As Hermans et al. indicate, examples that render this phenomenon evident include the huge number of multi-national corporations and global institutions, the growing number of migrations throughout the world and the creation of new geographical groups such as the European Union.

Since the traditional approach of cultural dichotomies is not effective in studying today's world, researchers are looking for alternative perspectives. Hermans et al. (1998) suggest focusing on the contact zones of cultures rather than on their center because it is in the periphery that cultures meet. Thus, instead of comparing countries or regions, researchers should study the cultural changes that occur in the meanings and practices of people as they interact with individuals of other cultural groups. Contact with members of other cultures may occur within one region, as is the case of multi-cultural societies. Some of the issues that could be studied include the way in which communication and misunderstandings in cross-cultural interactions produce cultural changes, and changes in beliefs regarding how a culture is perceived by members of other cultures.

Berry & Annis (1988) indicate that the powerful process of globalization and immigration that have taken place during recent decades are leading researchers to dedicate more attention to issues of diversity and acculturation within multi-cultural societies. These researchers argue that immigrants, native people, ethnic groups, refugees and sojourners are no longer merely considered 'minorities' but 'cultures'. Even when people migrate to other nations, many aspects of their cultural background prevail and even shape the acculturation process. Given the worldwide impact of international migration, cross-cultural researchers in education must avail themselves to what cross-cultural psychology offers (Harkness et al., 2000). This includes the knowledge and understanding related to the beliefs and practices that people bring to their cross-cultural encounters.

Comparative education, another discipline that has contributed to the development of cross-cultural research, investigates educational systems in different societies, including aspects related to educational modernization and reform (Fischer, 1970; Altbach, Arnove & Kelly, 1982). Like cross-cultural psychology, it developed quickly during the Cold War, when the 'superpowers' were trying to compete in every sphere. Knowing that education is a factor that influences scientific and economic development, these powerful countries kept an eye on each other's educational practices and concluded that the enemy was training their youth to believe in and to perpetuate an unjust economic and political system (Ryba, 1997; Matthews, 1982; Gutmann, 1999). The fast development of comparative education after the end of World War II was triggered by this interest in knowing about the educational systems of other countries. To understand the differences that exist between systems, comparative researchers analyze how a number of contextual variables (e.g. economic, political and social) interact with educational issues. Although cross-cultural researchers in gifted education have investigated topics that are commonly addressed in comparative education (e.g. international comparisons in academic performance), they have not focused so much on the relationship between educational phenomena and the economic and political context, but rather on the relationship between school/home environment and the cognitive, affective and social development of the person.

Comparative education has adopted methodological tools of other disciplines such as sociology, anthropology, political science, and economics. One of the methods that has been widely used in this discipline and that can be very helpful in cross-cultural studies in gifted education (e.g. in studying the beliefs and attitudes of groups of people) is content analysis. This tool is the systematic and analytical study of information that reflects people's minds as opposed to behavior (Krippendorff, 1980). It involves counting frequencies

of words in written or verbal productions in order to identify categories or themes that the researcher can then analyze from either a quantitative or a qualitative approach. This method can be used with a variety of research designs (e.g. statistical, descriptive, explanatory); and, although it used to be time consuming, the currently available computerized techniques make it very fast and convenient.

Cross-cultural research in education has taken knowledge and methodological tools from the previously mentioned disciplines. The first educational issues that were investigated cross-culturally were the universality of cognitive development (e.g. international studies on Piaget's stages of development) and the contexts for learning provided in different cultures (Harkness et al., 2000). With regard to the second, some aspects that were explored include the variability in learning styles and the differences in rearing patterns in collectivist vs. individualistic cultures. As cross-cultural research in education evolves, it is influenced by the same forces that have shaped the development of research strategies in cross-cultural psychology and in comparative education.

#### *Cross-cultural Research Types*

Van de Vijver & Leung (2000) developed a taxonomy of cross-cultural studies that is useful in identifying the strengths and weaknesses of the research carried out in the field of gifted education. It also provides some useful information to future researchers as they choose a research design and attempt to avoid methodological flaws. This taxonomy classifies cross-cultural studies into four categories: generalizability studies, theory driven studies, psychological differences studies and external validation studies.

In *generalizability studies*, a theoretical framework is developed and research hypotheses are developed. Usually, quantitative approaches are used to determine the universality of a particular structure (e.g. intelligence) without taking contextual variables into consideration.

*Theory driven studies*, like generalizability studies, have a strong theoretical background and a priori hypothesis that must be tested. This type of design differs from the previous one in that researchers gather contextual information and acknowledge the relationship between behavioral and cultural factors. The drawback, however, is that alternative interpretations are not considered when interpreting the results. Chen and Stevenson's (1995) study on the motivation and mathematical achievement of Asian-American, Caucasian-American, and East Asian students is such an example. Assuming that culture, through the social contexts of family, school and peers, has an impact on the academic achievement of students, the correlation between mathematical achievement and several characteristics of their cultural context was studied. It was

found that there is a relationship between achievement and several aspects associated with the lives of the students, including diligence and beliefs regarding the importance of effort.

*Psychological differences studies* focus on either exploring the stability of Western structures across cultures or on comparing cultures with regards to their scores on certain processes. Usually, instruments that were validated in one culture were used with other groups without consideration of the contextual factors. The open-mindedness regarding cross-cultural differences is the major advantage of using them, particularly when it comes to studying unexplored domains. The problem, though, is that once differences among cultures have been defined, the interpretation becomes ambiguous due to the lack of criteria to identify, among a large number of possible interpretations, a reliable way of explaining the results. The research of McIntosh, Nohda, Reys & Reys (1995) provides an example. The purpose of their study was to explore performance on several mental computational tasks utilizing a visual and oral presentation format. The correlations between levels of performance and contextual factors were not examined, but the differences in computational performance among American, Australian and Japanese students was analyzed.

*External validation studies*, like psychological differences studies, are not driven by hypotheses, but focus on exploration. They differ, however, in that the external validation studies consider contextual factors and are more successful in interpreting cross-cultural differences. The reason for this is that researchers examine the correlations between the indicators (i.e. possible explanatory variables) in order to discover a set of predictors or the general underlying factor that best explains each cross-cultural difference.

Bereday (1964) proposed an interesting way of classifying comparative studies based on whether explicit comparisons are made and on the level of their sophistication. Thus, studies are categorized according to the approach they follow in their comparisons. The *descriptive approach* is the simplest of all. Data is gathered on some aspect of education in one country and then it is described. In fact, this approach does not suggest any comparisons. In the second approach, called *juxtaposition and comparison*, data is gathered in more than one country and patterns are identified and compared. The third one is called *problems approach*. A problem or an issue is identified, data is collected in two or more countries, and the results are analyzed, usually in terms of implications and consequences. Finally, the last approach is *total analysis*. The ultimate objective of this approach is to develop theories or laws that can explain certain phenomena that are related to education. All aspects that affect, or that are affected by education, are considered and

analyzed. Most of the cross-cultural studies that have been conducted in gifted education have followed one of the first three approaches. The following section analyzes some of these studies.

### Cross-cultural Studies in Gifted Education

Due to the fact that giftedness is not objectively observed and measured and that there is no one single definition upon which all theorists agree, there are large variations among the studies with respect to their operational definition of giftedness. In some of the following cross-cultural studies, the authors explicitly indicate the type of giftedness that is being studied. In other cases, the researchers simply use the term 'high achievers' and do not delve into the subject of whether or not their subjects have any type of gift or outstanding talent. In still other studies, researchers only examine the factors that contribute to differential levels of achievement or the differences among groups on some variable associated with achievement, such as intelligence.

As mentioned above, cultural studies in gifted education differ based on whether data was collected from one or from at least two cultures. When only one culture is examined, the findings are sometimes compared with those of previous studies. However, the problem with monocultural research is that, although two studies may claim to examine the same process or construct, their operational definitions may be so different that no sound comparisons are able to be made. This section presents studies that are both representative of cross-cultural research in gifted education and which have focused on making explicit comparisons between cultures. For purposes of analysis, they were divided into three categories:

- (1) academic performance,
- (2) cognitive and affective issues
- (3) diversity in multi-cultural societies.

Some of the studies, however, deal with topics from several categories.

#### *Academic Performance*

One of the main interests of cross-cultural researchers in education is to determine how groups differ with respect to academic performance and what may be the cause of these differences. As far as research in gifted education is concerned, mathematics, science and technology are the fields in which cross-cultural differences have been widely investigated. In this part of the chapter, an analysis of the influence of gender on mathematical performance is presented, as well as the results of international efforts to compare the mathematical performance of several cultures.

Studies in many places of the world have consistently found differences in academic performance between males and females. Much attention has been paid to differences in the verbal ability of females who

perform better than males during the school years (Epstein, Elwood & Hey, 1998) and to the differences in mathematics particularly. Research studies indicate that although females do well in computational tasks, males outperform females in spatial ability and complex problem solving skills (e.g. Armstrong, 1985; Dossey, Mullis, Lindquist & Chambers, 1988; Becker & Forsyth, 1990; Gallagher, 1992; Low & Over, 1993; Benbow, Casey, Nuttal & Perzaris, 1995; Friedman, 1995). Even though the mathematical achievement of females in general has improved, a significant gender gap continues to exist in the gifted population (Kerr, 1994; Gallagher, 1996). These differences have been considered to be one of the factors that account for the under-representation of females in the fields of mathematics and science (Adams, 1996, Reis, 1998). While gender differences in academic performance have been widely investigated, only some of these studies have addressed giftedness issues from a cross-cultural perspective. The following is a sample of the topics that have been commonly investigated in cross-cultural research in gifted education, especially in mathematics; some of these studies focus on issues that arise in multicultural settings.

Chen & Stevenson (1995) studied the mathematical achievement of Asian-American, Caucasian American and East Asian high school students and found that the achievement scores of Asian-American students were higher than those of Caucasian-Americans, but lower than those of Chinese and Japanese students. The cultural factors found were associated with the Asian-American and East Asian students having had parents and peers with high academic standards, their belief in the importance of effort, a positive attitudes regarding mathematics, studying diligently and having less interference from jobs and informal peer interactions. It is possible that these differences in achievement may be correlated with how students allocate their time to various activities. For example, Fuligni & Stevenson (1995) examined the daily lives of American, Chinese and Japanese high school students to determine the amount of time devoted to a wide variety of activities. The interviews revealed that Chinese students spent more time than the American students in academic endeavors. Although no differences were found between Japanese and American students with respect to time spent studying or attending after school classes, the findings indicate that Japanese students spent more time attending school, whereas their American counterparts spent more time working and socializing with friends. Another study that involved Asian students indicated that, in the 8th grade, the mathematical performance of Hispanic students was lower than that of Asian students, with Asian females performing slightly higher than Asian males. It also showed that attitudes toward mathematics were good predictors of math achievement across cultures (Simich-Dudgeon, 1996).

Campbell & Wu (1994) used quantitative and qualitative research methods to study the factors that influence mathematical achievement among gifted and non-gifted 5th and 6th grade students from Taipei and Taiwan. Their findings indicated that boys received more pressure, support and help in intellectual pursuits and that, in the case of non-gifted boys, this additional pressure had a dysfunctional effect on their achievement. Non-gifted girls, on the other hand, were more neglected, as far as academics was concerned, but this did not undermine their overall achievement. In the case of gifted girls, more parental help was related to lower achievement in mathematics. These girls reported having more intellectual resources and, overall, experienced a near optimal mix of family processes that fostered their academic development. Similar studies (Campbell, 1994; Campbell & Uto, 1994; Pitiyanuwat & Campbell, 1994) found that certain family processes, such as support and intellectual resources, positively affected mathematical achievement, but that excessive pressure and parental help had negative effects among Greek American, Caucasian American, Latino, Asian American, Japanese and Taiwanese students.

Success in mathematical achievement has also been related to students' estimation and mental computational skills. Research studies among Australian, Japanese and American students (Reys, Reys, Nohda, Ishida, Yoshikawa & Shimizu, 1991; McIntosh, Nohda, Reys & Reys, 1995) found that there is a correlation between students' confidence in their ability to estimate and their performance on actual estimation tasks. It was also found that, whereas American students outperformed their Japanese counterparts on orally presented items, the opposite is true when the items are presented visually. To explain these results, the authors hypothesized that high scores on visual tasks may be due to a greater reliance on the use of the standard written algorithms, whereas a higher performance on the oral items may suggest a tendency to use invented mental algorithms. This is an area that requires further research. The performance of Japanese students was higher at the early grades but, by grade 8, it decreased when compared to the American sample and disappeared when compared to the Australian sample. It appears that Japanese students tend to apply learned computational procedures mentally, instead of estimating.

Among the first well-known systematic comparisons are the studies connected with the Olympiad competitions. Some issues that have been studied include the differences in mathematical performance between different countries and the way in which the competition impacts the subsequent development of the participants.

Although the International Mathematical Olympiad was first held in 1959, it was not until recently that American and Chinese scholars decided to conduct

joint research on whether the competition reached its stated goals (Campbell, 1996b). Studies (Campbell, 1996a) that analyzed various aspects of the Math Olympiad found that psychological support and parental help are the key to success in all cultures. Also, Olympians reported similar views across cultures regarding the attribution of ability and effort. American Olympians had a higher self-concept and published more research papers than their Chinese and Taiwanese counterparts, but also reported more hostility and claims of elitism. Although other International Olympiads exist, for example in physics and chemistry (Pyryt, Masharov & Feng, 1993), there are few cross-cultural studies on the characteristics of their participants and on the impact of these competitions.

Another important cross-cultural study in mathematical achievement is the Third International Mathematics & Science Study (TIMSS). It is the largest international study on mathematics and science ever undertaken and is conducted under the auspices of the International Association for the Evaluation of Education Achievement (IEA). This study focuses on making cross-national comparisons in educational attainment (Schmidt & McKnight, 1995). Three categories of characteristics, curriculum, instruction and student achievement, were assessed in more than 40 nations, among which Japan, the United States and Germany were the most widely studied. Some of TIMSS findings regarding curriculum and instruction (Beaton, Mullis, Martin, Gonzalez, Kelly & Smith, 1996) were as follows. Content taught in 8th grade math classrooms in the United States was at a 7th grade level in comparison with other countries. Topic coverage in eight mathematics classrooms in the United States was not as focused as it was in Germany and in Japan. American 8th graders spend more hours per year in mathematics and science classes than German and Japanese students. In regards to instruction, some of the findings indicate that in the United States and in Germany, the goal of the lessons is that the students acquire principal skills, while in Japan it is to develop mathematical thinking.

The findings of these types of studies are useful in determining what educational practices promote high achievement throughout a country and they provide invaluable insight as to what changes in curricular content and teaching strategies may be appropriate in different cultures.

#### *Cognitive and Affective Factors*

This section presents research studies that have explored cognitive and affective issues in which researchers have found are correlated with either high achievement or giftedness. The topics that will be analyzed include intelligence, creativity, learning styles, attributional style, self-efficacy, anxiety and attitudes.

Several questions have emerged in the field of cross-

cultural research regarding *intelligence*. Researchers have inquired into whether the structure of intelligence is the same across cultures and what relationships exist among the different intelligence tests and between these tests and other aspects such as personality and environmental variables (Bleichrodt, Hoksbergen & Khire, 1999). Bleichrodt et al. worked on the development of an intelligence test that would be useful in testing school-aged children in both India and the Netherlands. They developed the ICIT (Indian Child Intelligence Test), which is an adaptation of the RAKIT (Revisie Amsterdam Kinder Intelligentie Test). The test scores of Indian children were lower than those of children in the Netherlands in several areas. The researchers believe this could be due to the fact that children in the Netherlands start school earlier and that some children in India leave school earlier in order to work. In India, it was discovered that the scores for girls in three subtests (closure, verbal meaning and mazes) were significantly lower than those of boys. This may be due to the higher level of encouragement that boys receive to do well in school. Based on the overall results, the researchers concluded that a correspondence exists between the factor structure of both tests. This supports their psychometric equivalence. Research similar to this one has been done with various intelligence tests (e.g. WISC) as they are adapted to other cultures. Another topic that has been explored is the usefulness of different intelligence tests in identifying gifted children from diverse cultural backgrounds. Saccuzzo, Johnson & Guertin (1994a, 1994b), for instance, studied the effectiveness of the Raven Progressive Matrices Test (RPM) in identifying gifted children from cultural groups that are traditionally under-represented in gifted programs in the United States (eg., Latinos and African-Americans). They found that the RPM, as compared to the WISC-R, is a more equitable test for identifying students from ethnically diverse groups and for ensuring more gender equity. An aspect that has to be studied in more depth is the role of the environment, the culture and, in particular, of specific types of nurturing strategies in the development of intellectual abilities.

In the area of *creativity*, Lubart & Sternberg (1998) argue that this construct is time and place dependent and that it originates in the interaction between a person and his culture. Based on an analysis of previous research, it was concluded that the Eastern perspective of creativity does not emphasize innovative ideas, but that it focuses on emotional, personal and *intrapyschic* aspects of the creative process. In contrast, Western cultures have a problem-solving orientation and assume that creativity is linked to the creation of an observable solution that is novel and appropriate. The researchers also indicated that the level of creativity allowed and the degree to which it is fostered varies between cultures. In a study of technical creativity among Chinese and German students, Heller & Hany

(1997) found that the German students scored higher in the production tasks and in the practical verbal test of creativity. Chinese students, on the other hand, scored higher in logical thinking with geometrical figures and in the non-verbal part of the test, which involved constructing geometrical analogies. It would be a very interesting study to analyze, from a qualitative perspective, the mechanisms through which different cultures, and in particular these two, promote different levels of skills among their students. After more than two decades of studying creativity, Csikszentmihalyi (1988) concluded that it is not possible to study this construct by isolating individuals and their works from their social and historical environment. For this reason, the study of creativity is both fascinating and very complex.

With respect to *learning styles*, Milgram, Dunn & Price (1993) stated: "We are becoming increasingly aware of the unique impact of culture on intellectual and personal-social development, in general, and on giftedness and learning style, in particular." (p. xi). Because there are differences in the way individuals receive, store and retrieve information (i.e. learning style), it is imperative to provide educational experiences that respond to those differences (Dunn & Milgram, 1993). In a cross-cultural study of learning styles among students from Brazil, Canada, Egypt, Greece, Guatemala, Israel, Korea, the Philippines and the United States, Price & Milgram (1993) found that numerous differences exist among students from these cultures and between gifted and non-gifted students. One of the findings indicated that gifted students prefer learning alone rather than in groups. Even in the face of difficulty, they prefer to receive direction from an authoritative adult rather than work cooperatively with other students. This finding challenges the suggestion made by several researchers (e.g. Johnson & Johnson, 1985, 1989) regarding the benefits of using cooperative learning in heterogeneous ability groups. Other researchers (e.g. Anderson, 1988; Dunn, 1993; Ewing & Yong, 1993) have analyzed differences in learning styles among students of various ethnic groups in multicultural societies, finding differences between genders, between gifted and non-gifted students, and among ethnic/cultural groups.

*Attributional style* is related to the causes to which people attribute their successes and failures. Birenbaum & Kraemer (1995) studied the causal attributions for success and failure in mathematics and language examinations of Jewish and Arab 9th graders. Large gender differences were noticed in the mathematical abilities of Jewish students, with boys attributing success more to their ability in maths and girls attributing failure due to their lack of ability. Jewish girls displayed adaptive attributional patterns only in language. In another study, Heller & Ziegler (1997) examined gender differences in attributional

styles in Germany, Israel, China and Korea and successfully trained the female subjects to attribute their successes to ability and their failures to lack of effort and to certain external factors.

*Self-efficacy* is a person's beliefs regarding their ability to perform at certain levels in particular tasks (Bandura, 1994). One of the mechanisms that may increase self-efficacy is social persuasion which, like other forms of social interaction, is shaped by culture. Many studies have been conducted in this field in various countries and particular attention has been paid to gender differences in self-efficacy in mathematics (e.g. Junge & Dretzke, 1995), with the result that females have lower self-efficacy than males. However, there is a lack of studies that analyze this phenomenon from a cross-cultural perspective.

*Anxiety* is another factor that is strongly correlated with achievement. Satake & Amato (1995) found a negative correlation between math achievement and maths anxiety. According to their results, Japanese students experience high levels of anxiety when they have to perform calculations or solve problems. With regards to testing, it was reported that 5th and 6th grade female Japanese students experienced significantly higher levels of test anxiety in maths than their male counterparts, regardless of achievement level. It was also found that elementary teachers are more likely to call upon high achievers in order to give them more opportunities to demonstrate success in classroom performance, which is one of the criteria that determines whether a student will be admitted into a prestigious middle school.

Another area in which the negative effects of anxiety have been reported is computers. Due to technological advances and the need to incorporate computers into our everyday lives, it has become imperative to develop educational programs that guarantee computer literacy. However, affective factors such as anxiety have been found to affect one's success in learning to use computers (Marcoulides, 1988). It has been argued that these programs will be successful only if the presence of computer anxiety is accurately measured (Marcoulides, 1991). However, construct invariance, in this case computer anxiety, is a *sine qua non* in the measurement of psychological variables and must be taken into account when making comparisons across cultures. Having identified this need, Marcoulides (1991), tested the invariance of a two-factor computer anxiety model with college students in two different cultures. He found that his model was invariant, which means that his Anxiety Scale is useful in identifying individuals who experience computer anxiety. Rosen & Weil (1994) conducted a similar study, but obtained different results. Using factor analysis procedures, it was demonstrated that the meaning of the construct of computer anxiety differs across cultures. It was found that each country had a unique culture-dependent

model for computer anxiety. The results also indicated that computer anxiety for university students in the United States and in Australia meant students were anxious regarding learning to use computer technology, including encountering and dealing with problems. To other students, it meant visiting a computer center or sitting in front of a home computer. For American and Australian students, computer problems were a part of the process of learning to use the computer, but these problems caused anxiety to students from Germany, Japan and Israel.

*Attitudes* have also been investigated in the field of computers. In a study of Canadian and Chinese adolescents, Collis & Williams (1987) found that Chinese students had a more positive attitude regarding the impact of computers on society, that they showed a greater tendency to label computer users as smart and less to label them as unsociable and that they were less confident in their computer abilities than Canadian students. In this study, girls expressed the belief that women and men were equally capable in scientific and technological endeavors. Markrakis (1992) studied attitudes towards computers among Japanese and Swedish students. He hypothesized that gender differences in one's attitude towards computers would reflect socio-cultural structures and the efforts of each country in reducing gender inequality. His findings indicated that Japanese female students were more interested in learning about computers than Swedish female students based upon a more positive perception regarding the need to master computer skills. The findings also showed that Japanese students of both genders exhibited a greater tendency to stereotype the area of computers as a male domain. Markrakis believed that these differences were related to the cultural characteristics of each country.

Regarding attitudes toward gifted students, Feather (1988) investigated differences in attitudes toward high achievers in Australia, Canada and the United States. Because the cultures in these three countries emphasize individual values, the researcher expected that all students would be in favor of rewarding high achievers, rather than rewarding their defeat. Indeed, this is what his findings confirmed. On the other hand, previous research (Feather & McKee, 1993) had indicated that in collectivist cultures, people showed a tendency to want to see high achievers fail. Further research is necessary that investigates how people's attitudes toward high achievers influence the motivation of gifted and talented students to perform at high levels in different cultures.

#### *Issues of Diversity in Multi-cultural Societies*

The process of globalization and international immigration have produced deep changes in today's society. Some of these changes are related to issues of diversity and acculturation in multicultural settings. In the field

of gifted education, the problems that researchers have addressed include the identification of culturally diverse students, the creation of effective services and intervention strategies that adequately address their needs and the retention of these students in gifted programs. Some of the factors that have been studied include the adequacy of the instruments used for identification, differences in learning styles among cultural groups as previously discussed, the impact of non-intellectual barriers to achievement, and the classroom climate (Ford, 1994).

Most studies have been conducted in the area of identification of diversity. In discussions regarding identification, the psychometric, test-driven approach has been widely criticized due to its limited success in the identification of culturally diverse students. Consequently, efforts have been made to explore alternative ways of identification that are culturally impartial without compromising levels of excellence. Researchers at the Szold Institute for Research in the Behavioral Sciences in Israel (Zorman, 1997), developed a model to identify hidden potential in the visual arts and sciences through enrichment of students of various cultural backgrounds, including Arab, Jewish, Bedouin and Druze children. The model proved to be successful, but needs to be validated in other settings. Callahan, Tomlinson, Moon, Tomchin & Plucker (1995) used the Multiple Intelligence Model to identify and develop talent among minority and at-risk students. Some of their results indicated that student attitudes regarding self improvement and how their parents saw them were more successful. In another study, O'Tuel (1994) found that the Academic Program for Gifted with Excellence and Equity (APGEE) followed identification procedures that assured a more adequate representation of minorities, the disadvantaged, under achievers and persons with limited English skills into the program. Most of the systematic research in this area has been conducted in the United States (see Borland & Wright, in this book, Part V, chapter 3)). To find patterns across cultures more research needs to be conducted in other countries.

### **Future Directions in Cross-cultural Studies in Gifted Education**

This section presents several suggestions regarding theoretical, methodological and statistical aspects that should be considered in future cross-cultural studies. Although some of these recommendations were originally proposed in the field of cross-cultural psychology, they equally apply to educational research, including cross-cultural studies in gifted education.

Some of the following guidelines (guidelines 1 through 6) concerning theoretical, methodological and statistical issues derive from suggestions proposed by van de Vijver & Leung (2000). In various cases, perspectives from other theorists are added to the suggestions.

(1) Effort should be made to eliminate the various types of bias that affect cross-cultural research. To begin with, not only target constructs, but also presumed biasing contextual factors should be measured. This would allow researchers to verify or falsify particular interpretations of the differences found across cultures. Second, bias due to measurement artifacts may be dealt with by using at least three different methods when gathering data. Third, sampling procedures must be sound enough to avoid confounding cross-cultural differences with differences due to biased sampling. Borg & Gall (1989) indicate that sampling bias may exist when volunteers have been used, when subjects have been lost and when the subjects selected differ regarding important aspects. This would make them non-equivalent samples and the subjects are, to a large extent, not representative of the population. The fourth type of bias is very difficult, and in some cases impossible, to avoid. However, researchers must be aware of it. The values, attitudes and beliefs of the researcher, as well as the research paradigm being used, affect many aspects of the study. They determine what questions are asked and how they are answered and prod the researcher to ignore other methodological approaches.

(2) Instruments must adequately cover the constructs under investigation. If only one part of the construct is measured, the results cannot be validly compared to those obtained from studies that included other aspects of the same construct.

(3) When reporting results, effect size estimates should be used. They provide a clearer picture of the magnitude of the difference between groups, thus making them easier to compare. Significant levels may be misleading because they are a combination of cultural differences and sample size.

(4) Item response theory should be used in developing instruments for cross-cultural research. This modern theory of measurement provides useful guidelines in the construction and equation of tests that are intended to measure traits such as aptitudes and cognitive abilities (Hambleton, Swaminathan & Rogers, 1991; Stocking, 1999). Item response theory assists in adapting the instrument to the cultures in which it will be used. It also provides a useful framework for comparing scales that measure the same construct but that include non-identical items.

(5) The use of multiple latent variable models which include factor analysis (exploratory and confirmatory), path analysis and structural equation modeling, is recommended when dealing with complex, real-life phenomena (Loehlin, 1998) such as that found in cross-cultural research. Confirmatory factor analysis, termed a 'measurement model' in structural equation modeling (Byrne, 1998), is useful in comparing factor models of different groups. As van de Vijver and Leung indicate, structural equation modeling is useful in eliminating bias affecting observed scores by compar-

ing factors for which equivalence has been established.

(6) Van de Vijver and Leung indicate that multi-level modeling may be very useful in analyzing differences in the score levels among individuals of the same cultural group, as well as across cultural groups. It may also help determine whether a particular construct has the same meaning across aggregation levels.

(7) The ethnocentric approach, in which only Western instruments and perspectives are considered, should be avoided (Harkness & Keefer, 2000).

(8) Constructs must not be oversimplified (e.g. individualism vs. collectivism) (Harkness et al., 2000).

(9) As Keller & Greenfield (2000) suggest, methods that study behavior in context (e.g. naturalistic observation) should be included in the repertoire of methodological tools. Until now, most of the research has focused on variables that are verbally reported.

(10) Not only quantitative, but also qualitative methods are necessary in cross-cultural research. Researchers should avail themselves of the rich heritage of methods and theories that anthropology and psychology have to offer. In particular, qualitative methods may be extremely useful in gaining a deeper understanding of the nature of the cross-cultural differences and of the factors that generate those differences.

A comment is in order regarding the dissemination of cross-cultural and multicultural studies. The results of many investigations that cover a wide variety of educational topics, including issues of diversity in some nations, appear in publications that are not always accessible to English-speaking persons or persons from the Western world. When traveling to other countries, it is not uncommon to discover that researchers in different parts of the world are working on similar, or even identical, issues unaware that others are conducting the same research. Therefore, it is imperative to develop more effective means of making ideas and research findings accessible to wider audiences.

Finally, given that culture plays such an important role in human performance, it makes sense to emphasize the development of policies geared toward eliminating the disadvantages suffered by some groups in the field of talent development. In addition, researchers must be aware of how the political system in which educational practices are embedded influences the types of issues that are investigated and the methodologies that are chosen.

# Global Professionalism and Perceptions of Teachers of the Gifted

Alexinia Y. Baldwin<sup>1</sup>, Wilma Vialle<sup>2</sup> and Catherine Clarke<sup>3</sup>

## Introduction

The Terman studies set into motion an interest in the education of gifted students; however, one element of this educational package—the teacher—has gone without the intense research that other aspects of programming for the gifted have received. There has been little research which involved the direct observations of teachers in order to clarify those characteristics that are attributable to the teacher of the gifted rather than a global set of characteristics for all teachers. There has been a plethora of research reports on the interactions between teachers of the gifted and their students. Many of the studies that exist have focused on students' perceptions of various personality traits, intellectual acumen, and creativity of teachers of the gifted. From these studies, much has been extrapolated about the desired characteristics of the teachers of the gifted. The fact that these characteristics are good for all teachers makes it difficult for one to distinguish between those characteristics necessary for teachers of the gifted and the ones necessary for those who are not teachers of the gifted.

A series of questions were posed by Baldwin (1993) as the ones most frequently asked. They are:

- (1) Should the teacher of the gifted be highly gifted; if so what should the IQ score be?
- (2) How extensive should the knowledge of the teacher of the gifted be?
- (3) Should the basic characteristics required to teach gifted elementary grade students be the same for gifted students at all levels?
- (4) What type of educational background should the teacher of the gifted have?
- (5) What is the difference between a teacher of the gifted and a good teacher of all the other students?

- (6) What specialized training should teachers of the gifted have? (p. 621)

The question of the high intellectual ability needed for teaching gifted students is addressed tangentially by Skipper (1970) in his research with female pre-service teachers who scored at the 90 percentile or more on the American College Test and maintained a 3.5 average as university students. The premise of his study was that attitudes toward teaching as measured by several different scales would vary between intellectually gifted teachers and the unsampled set of pre-service teachers. The questions asked were: "... what are some of the personal attributes students may adopt from intellectually gifted teachers? Will gifted teachers' attitude toward students be conducive to the process of identification?" (p. 3). The findings of this study showed that the main difference in the two research groups was that intellectually gifted teachers like to discover new facts and have strong interest in skills required for science, and engineers. As teachers of the gifted it appears that the high intellectual teacher is more prepared personality wise, to help students process information and explore new ideas. This research showed, however, that the high intellectual teachers were much lower than the control group teachers in their interest in artistic affairs. Information processing and discovery of new facts are areas that have been listed as important for gifted students. Although this research might show that a teacher of the gifted who is of superior intelligence can address the areas considered important for gifted students of high *academic* ability what about those students who are highly creative—will they suffer? The answer to the question of how gifted must the teacher of the gifted be does not have an easy answer.

Much work has been done in the last ten years to develop standards for educational programs for teachers of the gifted. Knowledge of the domain—its constructs and the processes necessary to meet the needs of the gifted—have been the foundation for these standards as listed below. The literature which docu-

<sup>3</sup> Newcastle University, UK.

ments the efforts of researchers to answer the questions above has been an invaluable resource for the various committees' work on these standards.

The early research of Bishop (1968) which is referred to most often, determined that the teachers of the gifted in his sample were mature and experienced teachers of superior intellect. He also determined that they were creative, had high personal achievement needs and were student-oriented. Story's (1985) review of the literature revealed what she felt were important attributes of teachers of the gifted. They provide a supportive environment, have high verbal interactions, allow flexible scheduling, and give individualized attention. Whitlack & DuCette (1989) as shown in Table 1 also compared and ranked competencies for outstanding and average teachers.

Maker (1982) & Baldwin (1993) indicated that there are three important aspects of the educational development of the teacher of the gifted. These are: *philosophical awareness* of the constructs of education of the gifted which extends into a depth of understanding of human nature; *professional preparedness*; and *personal qualities* which are usually innate but can be enhanced through the proper training. These studies reveal the angst that researchers have felt in attempting to determine what is professionally appropriate for teachers of the gifted. They also provide the challenges that will face researchers in the future.

Since many of the questions listed earlier are still unanswered definitively, there remains a need to focus future research in these areas. Medley & Mitzel's (1963) statement over three decades ago that, "the development of a science of effective teacher behavior is almost certainly the most urgent research program that faces the profession today," is relevant for theoreticians and researchers as the agendas for

education of the gifted are set during the next millennium (p. 81)

## Professional Development

### Students for Teacher Training

Karnes & Parker (1983) reviewed the criteria used in various institutions. Out of this review came a recommendation that state certification should be based on "the prevailing philosophy that teachers for gifted program[s] should be practitioners of excellence in scholarly endeavours as well as in teaching performance" (p. 19). This earlier work has led to the development of Standards for Graduate Programs in Gifted Education as proposed by the National Association for Gifted Children (1996).

These standards for the post-bachelor's training programs for teachers of the gifted included four categories considered important in setting standards. The categories were:

(1) A *conceptual framework* which included the philosophy goals, and knowledge base of the curriculum. In summary, the proficiency expected in this area included a list of indicators of knowledge and understanding, the ability to interpret and apply this knowledge to identification, design of a program, the development of curricula, integrated instruction in a wide range of disciplines, and field experiences that are well sequenced and related to the conceptual framework.

(2) *Candidates for graduate programs in gifted education* which set a standard for candidates who had potential for professional success. Under these guidelines, recruitment and admission would be designed to attract a high quality of student including those from diverse backgrounds. The candidate should also have a

Table 1. Rank Order of the Ten Highest Rated Competences By the Outstanding and Average Teachers..

Item	Rank Order	
	Outstanding	Average
Likes gifted children	1	1
Ability to respond flexibly to the spontaneous needs of children	2	17
An advocate for gifted children	3	16
Emphasizes and looks for strengths in children	4	6
Ability to develop a gifted program appropriate to the needs of a particular community	5	36
Friendly, warm and accepting	6	24
Willingness to experiment with the unknown	7	20
Ability to admit error	8	5
Appreciates the uniqueness of individual gifted children	9	3
Encourages children to develop and present their own ideas	10	2
Ability to adapt materials (creatively and imaginatively) for the individual child	15	7
Ability to accept students' sense of humour	21	9
Fair (just)	23	4
Possesses and models joy in learning	26	8
Likes him/herself	33	10

Note: From Outstanding and Average Teachers by Whitlack, S. and DuCette, J., 1989, *Gifted Child Quarterly*, 33 (p. 19)

record of successful teaching and academic ability as shown by various methods of assessment. There should also be an ongoing assessment of their progress throughout the program to the completion of their studies.

(3) The *professional education faculty* included several indicators but stressed the requirement that the faculty would be trained in the field of education of the gifted and able to conduct scholarly research in this area. It was also indicated that the faculty in charge of training students in graduate programs of education of the gifted should have a doctorate degree. There should also be evidence of their collaboration with colleagues and practitioners in research, teaching, and placement of graduates of the program.

(4) *Necessary resources* included the need for faculty to be actively involved and provided the resources with which to work. This includes an adequate library, and other technological and media resources as well as appropriate and flexible load assignments.

The extensive detail of each of the categories represents a thorough self-analysis of the fundamental requirements for professionalism in this field.

As the field has grown, these criteria have been necessary for all levels of teaching in education of the gifted. Many of the training activities, however, are done as inservice with all teachers. Gross' (1997) research noted below focused on the effects of inservice and training on the change of teachers' attitudes toward planning and programming for the gifted.

### Research

It is quite evident that the primary focus of research on the teacher of the gifted has been the professional preparation of these teachers as shown by the many studies that have appeared in the literature. Berliner (1984) in his review of research on teaching cautioned that, "Teaching is a highly cognitive activity that requires an extraordinary level of competence for making decisions in complex and dynamic environments" (p. 52). This is important to understand as we attempt to make a science out of the field of education of the gifted. We can reflect on Berliner's summary of factors under a teacher's control as we consider the professionalism of teachers. The factors that can affect student attitude, achievement, and classroom behavior are: engaged time, time management, success rate, academic learning time, monitoring, structuring and questioning. He has strongly recommended that professional education for teachers should include a study of these factors.

In Gross' (1997) study of the effects of training and inservice on the attitudes and knowledge of teachers of the gifted, she indicated that the term *training* is more appropriately used for those students who are primarily enrolled in specialized degree programs at the graduate

level while the term *inservice* is more appropriately used for short term courses for teachers. She compared the shifts in attitude toward gifted students, of teachers enrolled in single day inservice and those enrolled in intensive training programs. The principal research questions were:

- (1) Do teachers in single-day inservice display significant positive attitudinal changes towards the gifted over the course of the inservice?
- (2) Do teachers in specialist gifted education training display significant positive attitudinal changes toward the gifted over the course of their training?
- (3) Do teachers in specialist gifted education training experience more powerful attitudinal changes than teachers in single-day inservice?
- (4) Do teachers who choose to enter an intensive training program in gifted education display significantly more positive attitudes towards gifted students than professional colleagues who do not choose to enter training?
- (5) Are there any aspects of the intensive training program, or any events or 'crystallizing experiences' associated with the program, which participants believe contributed significantly to shifts in their attitudes towards gifted students? (p. 12)

The findings of Gross' study indicated an expected difference in the level of change between the two groups in the area of knowledge gained and the confidence participants had in working with other teachers. Those who were in certificate programs were more prepared; however, on the two factors that traditionally have produced roadblocks for gifted programs—*needs of gifted and support for services and objectives based on ideology and priorities*—change as a result of both inservice and training experiences was evident. Gross concluded that planned professional training was certainly the important need for programs of the gifted, but inservice also plays an important role in changing the attitudes of teachers and administrators toward the value of addressing the needs of gifted students.

Studies by Hansen & Feldhusen (1994) focused on the observation of teachers who were trained in the education of gifted students vs. those who were not trained. Fifty-four trained and 28 untrained teachers in the field of education of the gifted were included in this study. Trained teachers were defined as those that completed three to five graduate courses and were teaching gifted students as part of their training. The 28 teachers included in the study were those who had been assigned to teach the gifted but had not completed course work in this area. The findings of this study gave evidence that trained teachers had greater teaching skills and were able to develop more positive class climates than untrained teachers.

In Australia, Whitton's (1997) study of the practices of 606 primary school teachers in New South Wales found that these teachers demonstrated a lack of knowledge about gifted children and made only minor modifications to their curriculum. This situation is attributed, in part, to the paucity of formal training in education of the gifted at both the preservice and inservice levels. Wellisch (1997) found that the younger the gifted child, the less likely their needs would be recognized and met by classroom teachers. Wellisch emphasized that teacher attitudes improve where they have some training in education of the gifted.

*Curriculum modification.* Reis & Westberg (1994) took another approach to looking at the effect of training on the development of good teachers of the gifted. This research focused on the ability of the teacher to modify curriculum for gifted students. The suggested type of modification was called curriculum compacting. The research questions that they wanted to answer were:

- (1) In what areas and to what degree do teachers modify instructional practices and regular curricular materials to meet the needs of gifted and talented students in regular classroom settings?
- (2) Is there a significant difference among treatment groups and teachers' decisions about whether they will compact curriculum in the future?
- (3) Is there a significant difference among treatment groups with regard to the quality of the compactor forms completed by teachers? (p. 130)

It was found that teachers modified mathematics and language most often. The results showed that there was a significant difference in those who were trained in curriculum modification following the curriculum compacting formula, and the groups that did not have the specialized training. In answer to the next research question, some of the teachers indicated that they would definitely use compacting in the future, however; statistical analyses showed that there was a lack of relationship between those in the various treatment groups. In response to the third question, the researchers found that the quality of the compactor forms increased as the training became more intensified.

#### *Holistic Professional Development for Teachers of Gifted Students*

In the United Kingdom, a very different approach to professional development has been taken by one researcher. It has been developed for the purpose of helping teachers to make appraisals of their teaching in an environment with other teachers. In this environment, teachers share their intellectual skills and help each other to grow in creative thinking, problem-solving and managing and organizing classrooms. Although this system is not without its problems,

narratives such as that which exist in the popular portfolios, is nevertheless a valuable way of researching the complexities of life in classrooms and schools. By focusing the process on the achievements of teachers as well as their concerns, efforts made by teachers to meet the needs of their gifted students are acknowledged and explicitly valued during the process. When this is done, ideas, techniques and approaches can be considered and accepted with modification or rejection.

Gifted students around the globe need to be nurtured if they are to achieve at the level of which they are capable (Matthews, 1997). Teachers play an important role in this nurturing and as Her Majesty Inspectorate in the U.K. reported, "The judicious intervention of the teacher to urge pupils to a higher level of knowledge, skill, understanding and thinking was crucial" (1992 p. viii). In order for teachers to function at their best and facilitate the learning of gifted students appropriately, they themselves need, what Brandis & Ginnis (1990) describe as 'nurturing' attention. Brandis and Ginnis see this as an integral aspect of holistic staff development, an approach to staff development which has as its aim student centered education. An holistic approach is described as being based on participatory management, close interpersonal communication, a strong school-wide commitment to minimum ground rules, self and negotiated appraisal, pre and inservice training which emphasizes positive human interaction, and a creative and open curriculum (p. 160).

Clark (1992, 1996, 1997) has explored ways in which professional development can be holistic and incorporate many of the characteristics as listed above. In order to be holistic it should be participatory, utilizing close interpersonal communication with a minimum of ground rules, giving the opportunity for self and negotiated appraisal, and emphasizing positive human interaction and creative and open curriculum. This research of teachers should start out by first celebrating their work-effort and helping them to know that what they did and were attempting to do every day in their classroom is valued. In this model, teachers are encouraged even at this early stage in the program to conduct research in their classrooms.

The hypothesis underlying this model is that it is more likely that teachers who have taken part in holistic professional development programs will be able to offer holistic educational experiences to their gifted pupils and this will in turn enhance their intellectual progress but also their emotional and social development. This model is based on the theory that teachers given a chance to talk generally about their school and their classroom experiences of teaching and learning and to examine through their personal research the areas they need to change or enhance, will become better teachers. As Schon (1987) suggests, they can begin to explain what is usually left unexplained and thus understand more clearly what they are doing

and why they are doing it. A holistic development approach can be done through several different activities; (a) through the use of teacher narrative, (b) through unstructured classroom observation, and (c) through action research.

*Teacher narrative procedure.* Eight primary school teachers all of whom were concerned to meet the challenges of individual differences in a mixed ability classroom, became participants in this study. Teachers were asked to keep a diary and prepare to deliver a short presentation about how they were currently managing and organizing learning in their classrooms and the concerns and issues arising which they wished to work on during the experimental session. The session agenda was agreed upon by the participants and this immediately put them at ease. First, they had to identify an area of their practice which they wished to change, after which they had to decide how they intended to implement the change, evaluate the outcomes, and plan for their future practice in the light of their findings. The group acted as a research community where each member had a chance to tell their story and present the data they had collected through reading and their classroom analysis. Responses from teachers were expressed in terms of how they were able to analyze their own teaching styles, their personal concerns about understanding the levels of abilities in their class, and modeling of this process with their students.

*Unstructured classroom observation.* This helps teachers tell more of the story about what is happening in their classes. These data in transcript form are used to facilitate a debate between the teacher in whose classroom the observation has been conducted and ideally two other colleagues who have participated in the observation provides the triangulation necessary for the analysis of data to be more systematic and rigorous. Observation which is unstructured seems to be particularly helpful because it can tell more of the whole story, that is, data collected can paint a full picture of what is happening. The ground rules for this discussion are exactly the same as those used for the discussion about diaries. A great deal of self-appraisal goes on during this time. The analysis of data provides a useful opportunity for story telling and the sharing of anecdotes which serve the purpose of making the exercise far less threatening and more meaningful.

*Action research.* This is the process of having teachers conduct research in their classes and implementing the changes that this research was able to show as needed. Clark (1997) explains that in this project teachers were taught how to do action research on the education of gifted children in their own classrooms and also on the education of gifted children across the school as a

whole. After identifying an area which they wanted to change, they had to decide how they intended to change it, implement the change, evaluate the outcomes and plan for their future practice in light of their findings. The group acted as a research community where they discussed their data and their analysis through engagement in dialectical dialogues which are diametrically opposed to the one being put forward. What this appeared to do was as one teacher said "open up new vistas" and it also encouraged the teachers to link the data with their experiences as teachers and learners. Some of the conversations focused on the wider issues of current educational, political, economic and social context which broadened the entire scope of the professional development project.

Holistic professional development does not fit the usual mold for developing effective teachers of the gifted; however, teachers who participated in these holistic professional development programs were prepared to take risks, consider alternatives, tolerate ambiguities, and encourage task commitment. They were able to give learners more time to study in-depth and were flexible in finding ways within themselves to model those competencies they wished to develop in their students.

### Perceptions of Teachers of the Gifted

Although much of the research presently available on the teacher of the gifted relates to teacher attitudes toward gifted students, assumptions are often made by researchers as to the desirable qualities of teachers of gifted students; however, there is comparatively little research that explores the attitudes of gifted students to their teachers. In an exploratory study, Vialle (1998) questioned primary school students (year 5 and 6) enrolled in a gifted program. In semi-structured interviews, the students were asked to describe the qualities that make a good teacher. The findings from these interviews clearly demonstrated that personal qualities are as highly regarded as academic qualities, a finding that is reminiscent of the study conducted by Abel & Karnes (1994). The students in Vialle's study rated understanding and helpfulness as the key qualities in their ideal teacher. Although their teachers needed to be smart according to 15% of the students, the ability to facilitate their learning through setting challenging tasks was described as a key factor by a large majority of the sample. A sense of humor, creativity, and curiosity were also qualities in their teachers that were highly valued by the students. Finally, the students required their teachers to make the work interesting and to be well organized.

### *Perceptions of the Characteristics of Teachers of the Gifted*

In a study by Ferrell, Kress & Croft (1988), "it appeared that there were characteristics of a teacher of

the gifted which were different from those of teachers who were commonly recognized as 'good' teachers" (p. 136). Efforts were made by these researchers to find characteristics of the gifted teacher by using the Teacher Perceiver Interview (TPI) Selection Research, Incorporated (1977). The themes of the TPI were seen by the researchers to be consistent with the qualities desired in a teacher of the gifted. These themes as described by SRI and shown in Table 2 are: mission, empathy, rapport drive, individual perception, listening, investment, input drive, activation, innovation, gestalt, objectivity, and focus.

In this study it was found that there were six themes that differentiated the two groups of teachers. They were focus, Gestalt, innovation, mission, rapport drive, and investment. The researchers found that three of these themes—Gestalt, innovation, and rapport drive were also characteristics frequently found in the literature on teachers of the gifted. Among these three, Gestalt was found to be the one important distinction. Other themes from TPI did not differentiate between teachers and non-teachers of the gifted. The researchers concluded that "further study is needed to pinpoint the qualities of teachers who work with children which differentiate them from teachers in other capacities" (p. 137)

The list of desired characteristics for the teacher of the gifted and the levels of training they must have appears to be endless.

### Summary

Professionalism of teachers of the gifted is a global concern. The paradigm for developing this professionalism is becoming more formalized around the world. Efforts to develop this paradigm have been more advanced in the USA but there are strong signs of a growing global acceptance of the value of teacher training in some systematic way. In each country, there will be political, cultural, and attitudinal factors that will require the basic paradigm to be shifted. Baldwin & Vialle (1999) have highlighted the importance of including in the paradigm for change a need to understand that giftedness can exist in many guises. They have encouraged that professionals in the field of education of the gifted, metaphorically 'lift the masks' and look beneath because there are many faces of giftedness. Tsui (1997) discussed the need for scrutiny of the principles underlying the policies that determine the programs to be offered. In a society whose educational system is academically oriented and where flexibility of teaching processes to accommodate different aptitudes and learning styles are not the rule,

Table 2. Description of SRI Teacher Perceiver Inventory Themes..

Theme	Description
Mission	Sees education as the foundation for all that comes later in a young person's life. This teacher wants to be a part of helping children to grow and maintain or improve society.
Empathy	Perceives the emotion of the moment and responds directly to the emotion. This teacher understands and accepts students' emotions on a cognitive level without trying to solve the problem for the student.
Rapport Drive	Sees him or herself as a warm friendly person who students like. This teacher works purposefully to build a positive working relationship with the students, which the teacher perceived as beneficial for the students.
Individualized Perception	Gets to know the individual needs and interests of each student and builds or adapts the educational program based on these need[s] and interests. Different activities are provided so that students can express their individuality through their work.
Listening	Spontaneously listens to others and facilitates the speaker by accepting what is said. This teacher perceives that the answer to the problem lies within the speaker and that talking will benefit the speaker.
Investment	Wants students to learn and sees any lack of student success as his or her concern. This teacher's satisfaction in teaching derives from student learning rather than his or her own performance.
Input Drive	Is excited about own learning and uses the new things learned to help others. This teacher is always seeking out new knowledge, learning from everything surrounding, including the students.
Activation	Sees success in learning as a key variable for helping students to learn. This teacher builds a wide repertoire of techniques to motivate learning and gets students involved in wanting to learn.
Innovation	Is looking for and trying new or different ways to approach learning in the classroom. This teacher focuses his or her creativity on helping students develop creativity and to become actively involved in learning.
Gestalt	Is well organized with a drive toward completing tasks even at a perfectionist level. This teacher transfers the need for closure to students but does so by working from where the student is.
Objectivity	Responds to the total situation, getting facts first before reaching a conclusion.
Focus	Has personal role models and goals which help him or her to move in a purposeful direction professionally. A major part of the goal involves teaching and this teacher sees teaching as a life-long career.

Note: From Teachers of Gifted Children by B. Farrell, M. Kress & J. Croft (1988). *Roeper Review*, 10, (p. 137)

the process for change requires an approach which fits the needs of the culture and the policies that exist.

A recognition of the need for this professionalism can be seen in the increased number of international students in the USA enrolled in graduate programs designed to provide training in education of the gifted. A three-summer program to obtain an MA degree in education of the gifted and a two-week Confratute (conference and institute) which is held at the University of Connecticut, Storrs, Connecticut, have provided during its 23 year existence, thousands of teachers, and administrators with inservice knowledge about processes to use in developing the abilities of gifted students.

Where funding is lacking for involvement in this training for international personnel, Baldwin (1986) has suggested that modules be transported and used for each level of training with each level becoming more comprehensive and inclusive. *Level one* module would include—awareness training, definitions, characteristics. *Level two* module would include—more indepth awareness, definitions, psychology of needs, identification, teaching strategies. *Level three* would include—philosophy, definitions, psychology of needs, identification, curriculum development, teaching strategies. *Level four* would include—historical perspectives, rationale for defense of programs, administrative strategies, psychology of needs, identification, analysis of assessment protocols, curriculum development, teaching strategies, models of evaluation, advocacy strategies.

The University of Nijmegen (The Netherlands) have developed a postgraduate training course for teachers (elementary and secondary levels) to meet the needs of teachers of the gifted. This course consists of 14 modules, each 40 hours, for theoretical and practical training in gifted education. After fulfilment of all requirements the teachers receive a diploma with the qualification 'Gifted Education specialist'. This course is offered in cooperation with the European Council for High Ability (ECHA); therefore, the diploma is called ECHA-Diploma. To-date, 200 teachers, mainly from Hungary, Austria, Switzerland, Germany, and The Netherlands have received this diploma. Currently almost 300 teachers participate in the training program.

Without exception however, there is a need for training of teachers globally which in turn will prepare them to recognize and meet the needs of children from all cultures who exhibit gifted attributes.

# Families: the Essential Context for Gifts and Talents

Joan Freeman<sup>1</sup>

## Introduction

There is no lack of evidence to show that children's development, outlooks and achievements are influenced by the life-style of the families in which they grow up, and that from the beginning, the urge to learn is tempered by opportunity. Simonton (1998), though, in his investigations of world-class achievers has shown that there is no ideal family for producing giftedness: his subjects came from very varied backgrounds.

Indeed, families vary greatly in composition—from isolated one-parent units in big cities, to large families which are well integrated within a local community; from African families where children are cared for by several 'mothers', to large polygamous families where the father is shared, as well as residential homes for children without parents. It is not an easy matter to separate the effects of interactions between children and their parents from those with the wider culture, because each family provides its own unique mini-culture, 'translated' and adapted from that of the greater society. This special context not only provides a guide for the children's development, but also largely defines the opportunities in which all the family members can exercise their abilities. As far as we know, human parenting is not driven by instincts; every individual mother and father decides what to do, based on their own culture, experience and hopes.

## The Early Promotion of Gifts

Children's aptitudes, in whatever area they show promise, can only develop into exceptionally high achievement in circumstances which are rich in the appropriate material and psychological learning opportunities. All long-term studies on the development of talent have shown the cumulative effects of family attitudes on high level achievement (e.g. Bloom, 1985; Freeman, 1991; Perleth & Heller, 1994). In general, as children get older, there is a widening gap in average intelligence scores between those from differently supportive homes (Mascie-Taylor, 1989).

Gifted achievement, though, cannot be predicted from early experiences alone: self-esteem, genetic, constitutional and social trajectories impose powerful limits. Using children's precocity as the prime identifying feature of giftedness is probably partly responsible for its later apparent loss, often called 'burn out', which is usually due to the others catching up. Giftedness may also take many different forms; it may appear in quite unexpected situations and at different points during a lifetime (Subotnik, Kassin, Summers & Wasser, 1993). Trost (1993) calculated that less than half of "what makes excellence" can be accounted for by measurements and observations in childhood. The key to success, he said, lies in the individual's dedication, but given a high level of aptitude, intelligence and other cognitive factors are the most reliable indicators.

In fact, very high intelligence, as measured by IQ tests, is by far the most popular criterion for defining children as very able or gifted. Just one problem is that IQ testing is strongly influenced by belief systems, learned in the family, which include social and moral values. An example is in the Stanford-Binet Intelligence Scale in the question "What's the thing to do if another boy/girl hits you without meaning to do it?" The correct response must involve forgiveness. Consequently, children who come from families who are part of that belief system are likely to be advantaged on these tests. The vocabulary aspect too is dependent on having heard those words.

A very close positive relationship was found when children's (Stanford-Binet) IQ scores were compared with their home backgrounds (Freeman, 1991). The higher the children's IQ scores, especially over IQ 130, the better the quality of their educational support, measured in terms of reported verbal interactions and activities with parents, number of books and musical instruments in the home, etc. In a detailed review of influences on the development of children's IQ, Slater (1995) concluded that the best predictor of all is parents' IQ, education and socio-economic status.

## *The family culture*

Due to its mediating role in a culture, the family 'belief system', or what is taken as 'common sense' in one

<sup>1</sup> School of Lifelong Learning and Education, Middlesex University, London, UK. E-mail: j.freeman@mdx.ac.uk

home, may bear little relevance to what is taken equally for granted by a neighbour. In his studies of creative people, Perkins (1981) found that they were able to produce great works, not solely as a result of their talent, but as a function of their values and beliefs, which were demonstrated individually in terms of originality, knowing, and independence. After all, as Csikszentmihalyi (1998) wrote, genius cannot exist independently of the culture: one has to be a genius in something. Lubart & Sternberg (1998) showed that culture influences the definition and expression of creativity, channelling it into certain task domains and social groups. "The quantity of creative activity can be further affected by cultural factors such as the value placed on conformity" (p. 59)

Cultural and family attitudes have a considerable effect on high-level achievement. For example, Berry (1990) found highly significant geographical and religious differences between Nobel prize-winners. In proportion to their numbers, Jews were heavily over-represented; in certain subject areas 50 times more. Zuckerman (1977) suggested that as 75% of Jewish Laureates came from lower socio-economic backgrounds, it could not have been social advantage which produced that excellence, but rather—in line with other research—the cultural influence of the family's drive for success. Indeed, in their late adulthood, the most successful of the Terman sample were neither distinguishable by IQ nor by earlier school achievement but by family background, notably the aim for success (Holahan & Sears, 1995). In many Pacific Rim countries, as well as Russia, measured intelligence is largely ignored and success is attributed to sheer effort, hence the growth of out-of-school crammers. Both Flynn (1991) and Stevenson (1998) have concluded that the culture of hard work is probably responsible for so many Asian youngsters' greater school and work success than their higher IQ class-mates. In fact, Hess & Azuma's (1991) in-depth research showed that American children needed much more help and praise than Japanese children in their motivation to learn.

Home outlook and style of upbringing provides a large part of the bridge between home and school. In Poland, Niebrzydowski (1997) compared mothers' styles of upbringing; mothers of high attaining kindergarten children showed a greater capacity to control the child. Being themselves more sensitive to the child's concerns and competent with educational problems allowed the child greater autonomy. When parents and teachers are in agreement, the path to the child's achievement is smoother, in ways which are not always obvious.

Positive cooperation may be seen, for example, in the amount and quality of homework that a child does, a well recognised factor in school success. In a comprehensive review of research on homework, Hallam & Cowan (1997) conclude that the family is essential for seeing that it is done by young children.

American teachers, pupils and parents appear to be more negative than Europeans. For highly achieving Canadian inner-city children the combination of positive parental attitudes, parent-school links, and homework were the three key supports for high level achievement (Zeigler, Hardwick & McCreath, 1989). In an overview of international research on education of the gifted, it was quite clear that without family support, schools would not be able to help a potentially gifted child to achieve (Freeman, 1998).

Cultural values may inhibit the achievements of bright children. These too can be subtle, such as the effect of expectations: if children do not fit the cultural stereotypes they are less likely to be recognised as potentially highly able. Currently, the common Western stereotype of a gifted child is of a weedy lad: he (for he is usually male) is bespectacled, lonely, and much given to solitary reading. He is, in fact, a juvenile 'egg-head', at times referred to by his schoolmates and maybe his teachers as 'the little professor'.

Very able children who do not speak the language of the test-makers or who think in different ways are also less likely to be recognised as having high potential. In an overview of 20 research-based international papers on the gifted disadvantaged across five continents, Wallace & Adams (1993) concluded that it is not only culture which can cut such children out of recognition and special provision, but poverty. There is, they wrote starkly, "the equation, in reality, of wealth with giftedness, special educational provision and giftedness." (p. 446).

Parents who have been brought up in culturally impoverished circumstances may lack familiarity with easy verbal communication, which affects their children's intellectual growth. Cultural disadvantage usually brings psychological handicaps in the areas of perception and attention, verbal and intellectual abilities, and motivation. Those parents who, for example, give orders more frequently than explanations are less likely to discuss daily events with their children. Where the children's questions are ignored or rejected, and play-material and psychological 'permission' to play is scarce, their development will be accordingly narrowed, and bright children may have to develop complex strategies to get any verbal interaction from their parents. The intellectual poverty of children from unstimulating homes is noticeable by the age of five years. Perceptual deficiency in children who are not talked with is shown when they recognise fewer objects and situations, and their interests are limited by their inability to describe them.

#### *The use of language*

The single most effective help parents can give towards future giftedness is the early encouragement and enrichment of language. Vygotsky (in Wertsch, 1990) suggested that with specific provision and mediation

(adult guidance, especially through language) children can learn at a far greater speed than otherwise.

Based on 20 years of experimental research, Fowler (1990) showed how enriched language enabled children to shoot ahead of others with equal measured ability. From the earliest days, the key for parents is to take turns with the baby at initiating and responding to communication; the parent is not teaching but enabling. Early fluency in using language involving stimulation and practice from adults, such as being read to and talked with from the time of birth, enables children to deal more effectively with later complexities. His follow-up of 14 children with enriched early language showed them to have become "outstanding students in school" in all subject areas including the sciences and mathematics. Looking at the early lives of recognised gifted adults, he found that they had enjoyed an enormous amount of verbal stimulation, both spoken and written. Radford, too, in his survey of exceptional early achievers, found that although some appeared to come from homes of low socio-economic status, these homes were all lively, stimulating, and usually highly verbal (Radford, 1990).

Advanced language is probably the first thing to look for in assessing a potentially high intellectual level, and the advantage usually lasts; infants are able to manipulate language correctly, both in its comprehension and its production, earlier than had previously been thought. In intellectually gifted children, this is followed by the ability to reflect upon and control language using metalinguistic abilities—a reflective attitude to the comprehension and production of oral and written language—which is different from ordinary verbal communication (Gombert, 1992). However, children who are advanced in verbal ability are not, on average, more advanced in motor skills (Robinson, 1996).

In poor countries, literacy is often the key to the promotion of giftedness; having a literate family both improves a child's chances of going to school, and encourages familiarity with the written word. But it is unfortunate that education is so often identified with status, self-esteem, and empowerment, because not all members of the family are seen as having the same needs or rights. For example, where women's lives are restricted to the home, they may be denied literacy; all communication with the wider (male) society being filtered through to them by their male relatives. Literacy for women has a proven value: in an area of high illiteracy, where one group of mothers were taught to read and a control group was not, it was found that those with even a little literacy produced healthier and cognitively brighter children (Hundeide, 1991).

Even within a strongly literate cultural tradition, one cannot make the assumption that parent-child relationships have a similar nature; adult development is as important as child development. Some mothers are aged 16 and some are 45; for this and other reasons,

their mental and educational development may be quite different. The interaction between parents and children is not just between them as individuals, but also between their cognitive capacities and needs, which change with age. For example, physical contact is most important in the first year of life, conversation and responsiveness in the second, responsiveness to the child's talk in the third, and from then on, more variety of contacts with a range of other adults. From the age of five, maternal responsivity is less important, but parental encouragement and the availability of a range of play materials and learning experiences remains salient. For example, a London study found that as children were learning to read, those who read out loud to their parents at home had markedly higher reading attainments than those who did not; this could not be explained by any factor other than their reading aloud (Tizard, 1985). Gottfried, Gottfried, Bathurst & Guerin (1994) found that "Ongoing reading to the child in the early years is consistently associated with gifted intelligence (130 IQ) at 8 years." (p. 161)

#### *Can parents make a child gifted?*

Studies of successful people brought Howe (1990) to the conclusion that "in the right circumstances almost anyone can . . . acquire exceptional skills" (p. 62). He argues that self direction, self confidence, a sense of commitment and persistence, can effectively produce gifted performance. But Freeman (1998) has responded that in all history "no one has ever taken a number of children at random and obliged them to practice to a world-class level of talent in any area." (p. 415)

In fact, attempts to analyse and teach the specific skills of expertise to adults have been carried out in laboratory studies for some years (Ericsson & Lehman, 1996). But even though motivation and practice made a vast difference to results in those strictly controlled conditions, the trainees differed in the level of expertise they could reach. The researchers concluded that the most important variable in gaining expertise is sufficient ability to gain a foothold in the learning process, and then to put in thousands of hours of learning and practice. Although Ericsson (1998) concluded that "expert performance can be attained without unique and innate capacities (talent)," he states that the mystery lies in the motivation for anyone to practice sufficiently to get there.

Children's interests may provide a clue. These offer parents a lead in selecting provision (Gottfried, Gottfried, Bathurst & Guerin, 1994; Renzulli, 1995; Hany, 1996). Able youngsters' interests and leisure activities have been found to be a reliable predictor of future high achievement in that area. Although such choice is largely self-directed, showing task commitment, intellectual abilities, persistence and other personal attributes, it also depends on provision and culture. Eighteen years after secondary school, 48 of the original 159 subjects of a high school in Tel Aviv,

Israel, were surveyed for their occupational accomplishments and outstanding career achievements. A third of the sample had continued to work seriously in their childhood leisure areas with relatively higher attainment than their school-fellows whose careers were unrelated to their interests (Milgram & Hong, 1997) It was concluded that serious adolescent leisure activities were highly indicative of future successful careers and that this form of self-identification should be encouraged and provided for.

### Parents And Children Together

Things that parents do together with their children have a far-reaching effect on the child's understanding: games, chatter, stories, even arguments can be a stimulating means of fostering the child's intellectual growth. The cognitive functions most closely linked to family social relationships are the executive regulators—the way we plan, monitor, and check the outcome of problem-solving; the system works because adults have learned it and share the same cultural assumptions. However, close friends of children, who spend more time with them than other children do, are also cognitive mediators, in that they help each other to understand the world.

The problem for research is how to establish what results in what. A highly verbal and demanding child, for example, can affect parents' behaviour by stimulating them to have more conversation and read more stories aloud. On the other hand, parents who talk to children a lot are themselves verbal people.

By adaptation from the study of animals (e.g. by Konrad Lorenz, 1965), it has been proposed that there are specific times in development when a child is sensitive to certain influences. Danger points in physical development were revealed at the time of the thalidomide tragedy—if the mother took the drug at a specific stage in the development of the foetus, the baby could be born with deficiencies related to that time. But the general existence of critical periods for cognitive development in human beings is less sure, although foreign language learning does seem to be affected in this way. Since attempts to acquire another tongue after 15 years of age are very much less successful than earlier learning, it is important to start language teaching as early as possible. In general, however, the benefits of good learning experiences in the early years can be lost if subsequent experiences are bad, and conversely, there can be substantial recovery if early bad experiences are followed by good ones in middle childhood.

Maria Montessori designed a system of early childhood education using the similar idea of 'prime developmental times' (Montessori, 1964). She wrote that should those special times be used well, then good learning will happen, but if not, the moment may pass and the child may not have the chance again. Intellectual progress is 'at risk' between 7 and 36

months, because that is a period which is particularly sensitive to lack of good stimuli. White (1985) concluded that probably not more than one in ten children get sufficient educational input at that time for the fulfilment of their potential. Shavinina (1997), suggested that prodigiousness is itself a consequence of accelerated development during sensitive periods, expressed in exceptional perceptions of the world.

### Imitation

The ability to imitate is extremely important in learning, and without it, the gifted would not reach their full potential. So fundamental and universal is this human ability that its absence in newborns is a sign of retardation. Imitation is not only a means of learning; it is also an emotional bonding process which begins from the first day of life, with the two-way imitative 'conversations', which mothers and babies enjoy. Mothers introduce their babies into their culture, such as one would do for a verbally helpless foreigner, by establishing a 'dialogue'; to do this, she is sensitive to what her baby initiates, as well as suggesting and demanding certain behaviours from him. She encourages the activities of which she approves and discourages those she considers inappropriate, trying to extend the baby's grasp of what is appropriate by being sensitive to signs, which she can reinforce, that he is understanding what is wanted of him. It is not just physical behaviour that she is moulding, but a conceptual learning system. From the earliest days, "Sensitive parents may not only be maintaining infant interest in the events during social interaction, but also maintaining infant state at an optimal level for processing information" (Messer, 1994, p. 27).

Babies initiate as well as imitate, making their own mark on their world. For example, those babies who are demanding may receive special family attention and resources, and if these demands are of an appropriate nature, they can stimulate the infant's intellectual development. But this option is not open to all babies—interaction is the key; it is only in families where the parents are good communicators that the baby's demands are likely to be beneficially effective. This implies a specifically active role for the baby, but one which also positively involves the parents. It is open to question, though, whether demanding babies are always those with the potential for high ability, and whether parents should stimulate passive babies into demanding more, on the grounds that this will encourage intellectual development.

The mother's emotions influence the interactions, which can significantly affect the intellectual growth of the baby; even infants of ten weeks can recognise the difference between happiness, sadness, or anger in the mother. Her happiness encourages them to explore, joy in one producing joy in the other, whereas her distress causes them to withdraw, her sadness producing sadness or anger. The implications are profound. A

negative emotional atmosphere inhibits good learning, but positive emotions have an encouraging effect; any condition that causes stress to infants increases their need for their mothers, and decreases their urge to explore. What is more, when toddlers experience a series of anxiety-arousing experiences, the effect is cumulative. Sensitive parents are aware of times when the baby's attention begins to diminish, and change their behaviour to keep its interest, such as a change of voice or holding the toy in a different light. Infants cared for in this way are more likely to persist with their own explorations later on, especially as the tasks become more complex.

### *The Promotion of Motivation*

Children's feelings about what they are able to achieve start early; young children do not understand ability in the same way as they will at about age 11. They start by expecting effort to lead to results (Heyman & Dweck, 1996). Differences in motivation to learn in young children may also be more connected to their ideas of goodness and badness than to specific ideas of intellectual competence. Increasing motivation to learn, then, implies taking the blame away from personal deficiencies, such as perceived low ability over which children have no control, and putting it on lack of effort or appropriate learning strategies over which they do have control.

Lehward (1990) concluded that the major base of future problem-solving behaviour at a gifted level is an infant's curiosity coupled with confidence to explore the environment, which each one acquires as the result of favourable social processes. There is evidence that four year-olds who have high self-concepts are not only more intelligent and socially responsible, but better able to plan ahead, which is a vital part of creative thinking (Mischel, Shoda, Flavell & Rodriguez, 1989). However, these studies involve difficulties in measurement, for instance in accounting for the effects of influences such as gender, education, and socio-economic-status. For example, Power et al. (1998) in Britain, investigated young men who had been identified while at school as 'academically able', and found that their perceptions of a masculine identity could either foster or jeopardise their academic achievement.

Empowering children by giving them a feeling of competence and a goal to aim for (even examinations) generally increases both their motivation to study and the accompanying rise in level of work (Freeman, 1992). On the other hand, too much adult control implies constant dependence on someone else's decisions, removing their 'locus of control'—the place from which power comes (Rotter, 1966). If children see control of their learning as outside themselves, resting with the teacher or some other authority figure, then they will tend to be less involved and motivated to work. The urge to learn may also be improved when poorly motivated youngsters are empowered to help

others, as when unsuccessful adolescents take on the role of tutors to younger children.

### *Improving motivation through feedback*

Knowing how well one is doing allows aims to be set at an appropriate level, avoiding both certain failure and too-easy success; both success and failure tend to perpetuate themselves. A parent or teacher can modify feedback to give a child the feeling of success by raising the standard of the task so that when the child succeeds, her outlook on learning is encouraged to be one of success and optimism. Motivational factors are as important to high-level human accomplishment as intellectual ones. The existing body of research on intrinsic (deep and meaningful) motivation, as distinct from superficially trying to please, is particularly relevant for high levels of performance. Deci & Ryan (1985) analyzed over 200 studies on motivation, from which they formulated a theory of human motivation, which included personality factors. They found that when children feel competent, it motivates them to exercise and elaborate their abilities.

Yet the situation is not entirely controllable by parents or other adults; children can interpret feedback in different ways, depending both on the psychological context and on the child's personality. Telling one child he is doing badly may be interpreted as an excuse to stop work because it does not seem worth the effort, while for another, the response may be an increase in motivation to prove 'them' wrong. Paradoxically, too much praise, particularly in a system of close supervision, may tell a child that he is doing the bidding of the teacher, rather than developing his own competence. It then becomes psychologically impossible for the child to feel in control of his own progress in learning.

All children, whatever their ability, want to feel effective and engaged by challenge, which must include a risk of failure; the gifted need challenge at least as much as any others. If children are given a superficial reward, such as money or sweets, they are far more likely to choose the easiest ways of succeeding, whereas if they are enjoying the activity for itself, they choose harder tasks, usually just above the level of previous success. When children are interested in what they are doing, they seem to have a natural tendency to take on challenges that exercise and expand their limits of competence.

Positive feedback, particularly a positive attitude on the part of adults, can be very effective; there is always something specific to praise, some form of recognisable success, and the possibility of offering a reward. Sloboda, (1993) found that the best music students had received more praise than the others, and their parents had made them feel 'special'. Negative feedback, such as sarcasm, punishment, or detention, are much less effective: for emotional reasons the child may have

been seeking extra attention, and such punishment may simply fulfil what was wanted.

### *Social cognition*

Social cognition is the way an individual perceives other people and comes to understand their thoughts, emotions, intentions, and viewpoints, first described by Flavell (1977); parents are cognitive mediators with a special relationship. Children's experiences in the family are used to develop a system of inferences which they use to make predictions about others, especially in relation to themselves, and consequently how they think and behave. Although social cognition is related to intelligence, actual social behaviour comes from children's involvement in a variety of social situations, and benefits from adult guidance. Socially positive attitudes, such as being sensitive to the feelings of other people, are more often shown by confident young children, especially if they are highly intelligent. They are also better at making use of adults as resources and tend to play more imaginatively.

To explore their awareness of other people's feelings, 3–6 year-old children were asked to predict what someone else would like as a birthday present, rather than what they themselves would like to receive (Flavell, Botkin, Fry, Wright & Jarvis, 1968). Each child was presented with an array of objects, and asked to select a birthday present for each of his or her parents, siblings, and teachers. Choices were judged as role-appropriate on the basis of age and gender. The 3 year-olds disregarded both the age and gender of the intended recipient, while 4 and 5 year-olds' choices represented a type of transitional level, and all the 6 year-olds made appropriate role responses. Age seemed to improve social cognition, which was more advanced for the highest IQ children in each age-group. However, the available research does not reveal a recognisable relationship between social cognition and actual behaviour towards others, whether intellectual or emotional; nor does this seem to be the case for moral reasoning.

It is strange that highly intelligent children are often thought of as having poor social cognition and therefore few friends. In fact, as research has shown (Freeman, 1997), they tend to have sympathy, adaptability and compassion in abundance, and do not usually choose to be without friends. Using one-to-one interviews in Germany, Rost and Czeschlik (1994), compared the responses of 50 high-IQ with 50 average-IQ primary school children, and concluded that the former were the better adjusted. Later, working with mixed-ability primary school children, they found that those with high-IQs were the most popular (Czeschlik & Rost, 1995).

### **Follow-ups**

Detailed studies of gifted children as they grow up at home are rare. In America, Feldman (with Goldsmith

1986) spent ten years following-up just six young boys, described as prodigies; he used a term from biology, 'trace elements', to describe unrecognised events which are vital for gifted development. In a historical case-study of outstanding individuals such as Darwin and Piaget, Howard Gruber (1981) saw a similar combination, and referred to such creative achievers as people in "networks of enterprise," i.e. they have many things going on at the same time. In a four-year research project, Benjamin Bloom and his team (1985) looked back at the lives of 120 young men and women who had reached world-class levels of accomplishment. The subjects told them that no matter what their initial gifts, those high levels of achievement were due to a long and intensive process of encouragement and teaching, usually combined with long hours of practice under parents who drove them hard. Although several crucial factors which appeared to help the potentially gifted to achieve highly have emerged from such studies, we do not know what the effect of similar parenting behaviour would have been on other children, as there were neither comparison groups of families, nor any more intimate view of their lives—in fact, most of the Bloom interviews seem to have been done by telephone.

In a review of 14 American and German follow-up studies of varying design and loss of subjects over time, Arnold & Subotnik (1994) suggested an "inextricable link" between the identification of potential and timing due to age-related stages of development: accuracy in predicting achievement increases with the age of the sample studied. Accordingly, for the greatest reliability, information should be collected at different points in an individual's life, most reliably within specific subject areas in which the child shows promise and interest.

Reports from a 15-year Chinese study of 115 extremely high-IQ children (Zha, 1995), showed the strong influence of family provision, both in achievement and emotional development. The children were first identified by parents (two boys to every girl) and then validated as gifted by a psychologist; every year parents were given a questionnaire and interviewed several times. The parents-to-be had taken their future responsibilities very seriously by studying parenthood. As the toddlers were learning to speak, the parents often taught them to read, and some children even mastered writing at the same time. By the age of three many children could recognise 2000 Chinese characters, and at four many could not only read well, but also wrote compositions and poems. However, these 'hot-housed' children were found to be lacking in easy social relationships, and the parents had to be given some more lessons in how to help their children to some social life.

Measurements of certain aspects of learning in the first three years of life provide reliable indicators of life-long attributes, such as advanced physical control,

which can predict gymnastic talent (Lewis & Louis, 1991). The strongest early indicator, which can be traced from the age of three months, is verbal ability, but spatial and non-verbal signs are also valuable indications for future talents. These researchers found that the greatest overall intellectual stability was at the extremes of the IQ range—both gifted and low—and suggest that this intellectual development is qualitatively different from that of individuals with more average scores. Indeed, the parents of the exceptionally high IQ children in the follow-up study by Freeman (1991), compared with those of more average IQ children, reported very early signs of exceptional concentration, memory, and talking. Clearly, early infancy is the time when family sensitivities and influences are the most vital means of developing potential giftedness.

A unique study in California began with 130 one-year-olds of unknown potential, the only criterion being that they were healthy (Gottfried, Gottfried, Bathurst & Guerin, 1994). Various measures of intellectual, physical and social development were made regularly until they were 9 years old. Those with an IQ of 130 or more on the Wechsler Intelligence test were designated gifted and compared with the others. The researchers concluded that giftedness is a developmental phenomenon, which can rise—and fall—over time: late bloomers' do exist and can be missed in a single testing. In a detailed examination of the family environments, they found a rich continuous educational environment to be essential in developing intrinsic motivation for curiosity and love of learning; children from higher SES families tended to have higher IQs. According to the researchers, this was neither due to the parents' occupations or intelligence, nor to the amount of parent-child contact, but rather to the parents' educational accomplishments. "The families of gifted children provided more stimulating activities than did the families of non-gifted children. Moreover, the parents were more involved and apparently more invested in providing their children with a cognitively advantageous home environment" (p. 156). These differences, which were clear at three years-old and remained throughout the early elementary years, were notably of an academic and cultural nature, such as use of library or musical instruments. The gifted IQ children also influenced their environments, demanding more learning activities compared with the non-gifted children.

### **Individual Differences Within Families**

Most studies of the effects of the social environment on children's development examine factors that are supposedly similar for all the siblings in the family, such as social class, marital conflict, or pressure to perform. But a child is neither a passive nor an unbiased recipient; there are indications that the most influential environmental factors may be those which are different

for siblings in the same family (Dunn, 1984). Thus, there may be social and biological mechanisms which increase the differences between experiences which siblings have in the same family. These are termed non-shared environmental effects, and might, for example, include variations in how each child is treated by the same parent, peer relationships, school interactions, and when they are older, differences in their marital and occupational experiences. Discovering exactly how different kinds of influences are received by different kinds of children is extremely difficult; parental divorce, for example, might either cause a temporary halt to a child's development or have life-long effects.

In order to study family interaction effects on different siblings in a family, it would be necessary to define the individual difference between the siblings (in families of at least two siblings) and the relationship of these differences to simple family structural variables. Only then would it be possible to distinguish the environmental variables which are likely to be important developmental differences. These could be relationships with the parents, as in the study which showed considerable consistency in parent's differential treatment of their children (Abramovitch, Pepler & Corter, 1982). There are also the differences in the way siblings see themselves as being treated by the family, and peer group relationships can also be different for children in the same family.

To some extent, these differences are attributable to recognised variables such as birth order, age spacing, and gender. Gottfried, Gottfried, Bathurst & Guerin (1994) found, as have many others, that birth order was important; firstborns and only children do better. They strive harder to please their parents because they identify more strongly with them, and in addition to having higher IQ scores, they usually achieve more than their siblings throughout life. Even their leisure-time pursuits often have an educational aspect. First-born and only children are more likely to be more concerned with the effect they have on adults, and to be more responsible; the second-born is more easy-going and has more friends; the third-born is often more difficult to live with; while the fourth is often babied and so learns to be more dependent.

Speed of reaction may also be an innate ability which shows itself in many facets of behaviour that can affect relationships, etc., and which are regarded as important if not vital aspects of intelligence (Eysenck, 1998). There has also been considerable evidence of even young children's ability to shape interactions with their families; indeed Scarr & McCartney (1983) have suggested that to some extent, children make their own environments. Long-term research (eg. Reiss, Plomin & Hetherington, 1991) has shown that children may identify with one parent and strive to follow the path of that example, differentiating themselves from the other siblings, and so accentuating different parent-child relationships.

Studies in various parts of the world have concluded that better nutrition leads to an improvement in children's IQ scores, correlated with increases in their head size and height (Lynn, 1989). Clearly, the better-nourished child will function more effectively at a biological level, and this can be expected to support a higher level of mental functioning; it could make the difference as to whether or not giftedness will develop in bad circumstances. This effect is recognised for instance in Brazil and some areas of the USA, where feeding very poor children is an important part of school life; indeed, it is some children's reason for coming to school.

### *Gifted Girls and Boys*

Many studies have shown that in most cultures, families encourage boys more than girls to be independent, self-reliant, and able to assume responsibility, and that this alters their approach to both school and work. In Germany, Rost & Hanses (1994) found "dramatic gender effects" in the toys gifted children were given. There is a strangely stable ratio of two boys to every girl when parents identify their children as gifted; this was the proportion in an American study by Johnson & Lewman (1990) of parent's selection of four to six year-olds as gifted. In China, in a 15 year follow up study, in which parents made the first judgement of giftedness, which was then confirmed by the teachers, 69.5% were boys and 30.5% were girls (Zha, 1995). Given the supposed differences in the Chinese attitudes, in which girls are seen as inferior, remarkably similar proportions appeared in Freeman's U.K. study (1991) where parents made the first recommendation—64.3% boys and 35.7% girls. The reason appeared to be that the boys had more behaviour problems as well as being more demanding in general; this also fitted better with the stereotyped image parents often had of the gifted child.

The effects of being a boy or girl are different for the gifted than for those of more average ability (Freeman, 1996); many studies have shown gender to be the strongest single influence on high level achievement. Intellectually gifted girls appear to be cognitively more like gifted boys than girls of average ability (Stapf, 1990). Emotionally, though, in America they have been found to be more depressed than equally able boys, often underestimating their abilities because of conflicts between of success and 'femininity' (Luthar, Zigler & Goldstein, 1992). Golombok & Fivush (1994) wrote that: "Careful statistical analyses across hundreds of studies have demonstrated that gender differences in ability in maths and language are so small as to be virtually non-existent for all practical purposes" (p. 177). They concluded that the measurable sex differences in aptitude are due to "a complex interaction between small biological differences and larger gender differences in socialisation experiences" (p. 176).

However, schoolgirls in Britain are currently achieving higher national examination grades than boys in all subjects at 16 and in everything except physics at 18 (Arnot, Gray, James, Rudduck with Duveen, 1998). Several other countries are moving in this direction, notably Australia. Investigating mathematically precocious American youth, Benbow & Lubinski (1993) although recognising the effects of cultural influences, concluded that there is a genetic mathematical bias in favour of boys. The British results, though, refute this. Taking a long-term look at giftedness in mathematics in the USA, Jacobs & Weisz (1994) found that parents held somewhat fixed and conventional gender expectations; this influenced the girls' self-esteem more than their actual performances, and inhibited their ambitions. Power et al. (1998) in Britain, investigated young men who had been identified at school as 'academically able', and found that their perceptions of a masculine identity could either foster or jeopardise their academic achievement.

An international review of research on gender differences in the highly able in mathematics and natural sciences, failed to find any reliable evidence that girls are inherently less able than boys in these subjects (Heller & Zeigler, 1996/7). So, because they have similar abilities, girls and boys can act as experimental controls for each other to gauge the power of social effects, probably best seen in career outcomes. Heller pointed out that, for example, even on present tests of spatial abilities at which boys do better, we could expect only twice as many male engineering graduates as females, whereas there are 30 times as many. This effect was found to be more pronounced among the gifted. Clearly, girls are being more influenced by social pressures than boys, e.g. by the 'unfemininity' of subjects such as physics, as well as much less practice and fewer role-models. Most importantly, the often-noted 'learned helplessness' of girls (a feeling that events and outcomes are beyond their control) was considered to be the result of 'wrong' attributions, so that girls often think their success is due to luck rather than their own ability. Thus, Heller states, believing that they are not good at maths, simply lucky to have done well that time, girls adjust their behaviour to fit their belief (attribution), and 'confirm' it by doing less well as time goes by.

### *Biological Differences*

There is a limit to the extent that family influences can affect children's achievements because of biological differences. The IQ scores from studies of more than 400 sets of identical and non-identical twins separated at birth were investigated in later life (Plomin, 1998). This work discovered about 70% genetic influence on IQ, the strongest correlation found for any psychological characteristic; in isolating the genetic input, such studies have highlighted environmental influ-

ences, notably that the younger the child, the more potent the environment. However, no specific gene for giftedness has yet been discovered.

Lykken (1998) points out that identical twins are affected by uterine environmental influences, causing differences, e.g. in size and handedness, in quite enough ways for parents to tell them apart. It is the configural or 'emergenic' aspects of inheritance, he writes, which mark the truly gifted from the merely assiduous. He demolishes the idea that it is only practice which makes perfect, pointing out that perfect pitch or the aptitude to become a Olympic gold medalist are not the birthright of every child.

The perceptual responses of even tiny babies to shapes and noises can be related to the type of care they receive, which in turn reflects the care which their parents themselves experienced. Harlow's (1958) observations of monkeys were the basis for work which showed how both animal and human behaviour patterns are learned and transmitted over generations; but of course, the baby's individual responses are important. For example, girl babies seem to have more sensitive skins than boy babies, responding more positively to stroking, which reinforces the parent's pleasure in doing this, so that baby girls may receive more soothing attention of this kind; similarly, heavy babies often respond less quickly than thin ones, which must affect parental responses to them, and they seem to continue in this way as children.

Freeman (1983) concluded that genetic and environmental influences on IQ are unlikely to be in the same proportion for all children. She found that when their environmental support was poor, children, who scored in the top 1% on the (relatively culture-free) Raven's Matrices test of intelligence, sometimes scored at a much lower level on the Stanford-Binet test (contaminated by learning). However, the brightest appear to be relatively more able to extract benefit from whatever environment they are in.

### *Emotional Influences*

Although gifted children are possibly more sensitive than others to emotional nuances in the family, there is no evidence that they are emotionally less stable than other children—even though it is sometimes argued that they are. On the contrary, an American meta-analysis pointed to low intelligence and attention problems as being associated with delinquency (Maguin & Loeber, 1996). Investigators who describe the gifted as having emotional problems have usually taken their data from clinical settings and case-studies, where the population is self-selecting and no comparisons are made with other equally able children (e.g. Silverman, 1993; Gross, 1993). In fact, the gifted appear to be emotionally stronger than other children, with lower levels of anxiety, higher productivity, and higher motivation. Perhaps those who are to be high

achievers need to be stronger than most because their exceptionality makes them more likely to come up against some special problems.

Research, unique in its in-depth approach, was carried out in Britain over 14 years (Freeman, 1991). A target group of 70 children, identified (but untested) by their parents as gifted, were compared with a second group of 70 who were unlabelled—but of equal measured ability—and a third group of 70 randomly selected children. In the target group 82% of parents either reported emotional problems or were expecting them. Typically, the child showed over-activity, clumsiness, tantrums, excessive demands, poor sleep and had few friends of any age. However, the comparison children in the study—of identical high ability—who did not exhibit problem behaviour, were much less likely to be seen as stereotypically gifted, simply outstanding at what they did. Freeman also found that about 10% of the children presented by parents as gifted were only of average ability on IQ tests, and had achieved accordingly at school; this perceived 'failure' was then sometimes blamed by parents on the school, or as teacher discrimination against the child. Ten years later, the parent identified youngsters had often remained the least happy (as measured by rating scales), for which their gifts were sometimes blamed. Labelling appeared to have the effect of putting pressure on children to live up to it in high achievements, notably those who had been wrongly labelled and could not fulfil their parents' ambitions. Whatever problems already exist in the family, these can be intensified when there is an unusual child present.

Emotions help or hamper learning at all levels. German research on gifted young children has found that fear can inhibit the development of curiosity, an important motivator in learning, thinking and creative endeavour (Lehwald, 1990). Boekaerts' (1991) overview of international research on the learning of gifted young children found that those who achieve most highly are not only very curious but have a hunger to learn, often along with a strong urge to control. Canadian research with young children has also found an extra quality of playfulness in the learning of highly able little children (Kanevsky, 1994). Investigating the current work of creative scientists in California and later that of living 'classical' composers, although some of this work was retrospective, Simonton (1994) could demonstrate that above a certain high level, personal characteristics such as independence contributed more than intellect to reaching the highest levels because of the great demands of effort and time needed. Perhaps for that reason, a four-year follow-up investigation of talented American teenagers, Csikszentmihalyi et al. (1993) found that in learning to tackle difficult tasks, the stronger the social support the more developed the youngster's skills, though schools were found to be much less effective in this than parents.

Vygotsky's (in Wertsch, 1990) Dynamic Theory of Giftedness suggests that either giftedness or defectiveness are possible outcomes when a child is faced with emotional barriers to development. Failure to overcome such barriers can lead to a child hiding behind the weakness, which then becomes reinforced. In a six-year experimental study in Moscow (Babaeva, 1999) investigated how to overcome such barriers in 31 children aged 6–7, identified as non-gifted by teachers and conventional tests. Following a specially devised therapeutic educational programme of 6 years, measures of the experimental group's abilities were equal to those of the identified gifted children, and considerably surpassed those of the non-gifted control children.

Even often-referenced studies may have tiny samples which are possibly unrepresentative. In Australia, Gross (1993) used the contentious IQ of 200 to select just three 'profoundly gifted' young children. They were described as exhibiting the 'typical' gifted symptoms of emotional disturbance, such as school-refusal and friendlessness, because for them, Gross wrote, being with normal children was the same as interacting "solely with children who are profoundly intellectually handicapped" (p. 475). But are the described heavy emotional problems a result of subtle messages from home that the child is 'too clever' and thus too sensitive to fit in socially? No comparisons with other children were made.

In fact, some studies of the gifted have found them to be emotionally stronger than others, with higher productivity, higher motivation and drive, and lower levels of anxiety. An Israeli study (Kener, 1993), found that gifted junior-school boys and girls showed significantly higher self-esteem when compared with those of average ability from similar backgrounds. In Italy, a sample of 300 high school pupils were given tests and open-ended questionnaires, although the follow-up only managed to trace 63 of them eight years later (Boncori, 1996). There were three sub-samples, 'highly gifted' (the top 10% of the general population), 'less gifted' and 'average'. The 'highly gifted' not only had far greater academic success than the other two groups, but also right through university enjoyed better social integration, wider interests, less materialism—and more satisfaction.

High achieving learners and labelled 'gifted' children are sometimes susceptible to extra pressure from parents to be continually successful, possibly at the expense of more challenging intellectual, artistic and emotionally satisfying activities (Freeman, 1997). What is more, no individual can perform at a high level all the time, not least because these children's abilities may develop at different and extreme rates, which can bring difficulties of coordination (Terassier, 1985; Silverman, 1993). Additionally, the highly able may suffer from false stereotyping and its expectations—along a spectrum which varies from expecting them to be emotionally handicapped to perfect in every respect.

Fear of failure and feelings of failure and of disappointing others' expectations are likely to develop, with possibly negative emotional consequences for life.

The particular pressures which the very able may experience, usually stem from others' reactions and expectations of them. For example, although the gifted may be expected to be too clever to enjoy normal relationships with ordinary people, in most findings, higher IQ youngsters have better all-round social relationships (e.g. van Leishout, 1995; Boncori, 1996). Other researchers have pointed to the tendency to perfectionism in the gifted (Stednitz, 1995; Robinson, 1996). Nevertheless, we cannot be sure about the causes, or whether this kind of obsessionality is found more among the gifted than other children; certainly the gifted can suffer from adults who mistake the abilities for the child.

### Conclusions

All babies are born with potential, but it is clear that only some develop this to its full, and fewer still to a recognisable level of excellence. What is it that makes the crucial difference in later behaviour between people who start out in life with much the same potential ability? That vital provision starts in the family; parents have to be both willing and able to make the effort if their children are to take advantage of the opportunities that exist around them. However, there is no single type of parent-child interaction which is critical to the development of high level abilities in children; the process is complex because parents and children each have their respective intellectual capacities as well as their own personalities, but genuine and regular interaction between parents and children is decidedly effective.

Good parenting for nurturing and enhancing children's gifts involves the following:

- Interaction between parent and children from birth, which is positive and supportive, providing a structure in which a child can grow with security.
- Meaningful stimulation, which provides opportunities for children's learning, including other people outside the family, especially as the child develops interests which may need specialist help.
- A variety of experiences, which can be followed up by the child if wished.
- Provision of both materials and tuition with which to reach advanced heights of learning and creative production; this includes good relations with the child's school.
- Gifted children need the emotional freedom and materials to play and experiment, both for their mental health and for creative thinking. Would-be artists need far more than a few scraps of paper and a pencil stub, a mathematician needs a teacher, a linguist has to hear the language, and a budding violinist needs the instrument.

- Teaching skills are needed by parents to develop general and specific areas of their children's potentials. This starts with the basic teaching of language, and through it the family culture.
- Sensitivity of parents to their children's potential talents from a very early age is different from attempting to mould them into the image that the adults may prefer. Knowing when to take action and when not to is a matter of sensitivity. Parents also have to be aware of their own feelings, notably to avoid labels and categories such as gender, in bringing up children who can demonstrate their gifts.
- Children need to be taught specific skills and be given the opportunities to practise them.
- Real emotional support is not quite the same as love: parenting in the name of love can be directive and so inhibit the growth of children's gifts where they are not acceptable. Pride and pleasure in children's accomplishments (or efforts), along with suggestions and encouragement to practice, provide excellent feedback for improving performance.

Like other children, the potentially gifted with emotional problems generally achieve less well than those of the same ability who enjoy peace of mind. The best results in human terms are found when children are treated with respect, allowing them enough responsibility to make many of their own discoveries and decisions. There are some, though, especially in the arts, who seem to have an inbuilt impetus—a spark which can light up the world, bringing them great inspiration and success.

# Identifying and Educating Poor and Under-represented Gifted Students

James H. Borland<sup>1</sup> and Lisa Wright<sup>2</sup>

## The Extent of the Problem

### *Historical Indicators of the Under-representation of Economically Disadvantaged and Minority Children*

It has been a commonplace observation, usually accompanied by sincere but ineffectual expressions of concern, that certain children have been and continue to be chronically and systematically, if unintentionally, under-represented in programs for gifted students. In the United States, under-representation has been primarily associated with economic disadvantage and racial and ethnic minority status. This is the situation that we will address in this chapter. Our knowledge of gifted education in other countries is insufficiently comprehensive to permit us to generalize globally, although we would be surprised if the forces that have led to inequities in the identification and education of gifted children in the U.S. were absent or, some particulars aside, radically different in many other countries.

From the very beginning of the field, individuals labeled as gifted, either for educational or research purposes, have deviated significantly upward from population-wide demographic patterns. For example, in *Hereditary Genius* (1869), Sir Francis Galton concluded that eminence in 'mental work' is 400 times as likely to be found among children of upper-class parents than among the children of laborers. Somewhat later, in *Mental and Physical Traits of a Thousand Gifted Children* (1925), the first volume of Lewis M. Terman's *Genetic Studies of Genius*, the author revealed that, whereas 4 to 5% of the adult general population was engaged in occupations denoted as 'professional', 50% of the fathers of his high-IQ subjects were so-classified. Moreover, children of Italian, Portuguese, Spanish, and Mexican descent were statistically under-represented, and the nearly

total absence of African-American children was so much in line with expectations that it was not deemed worthy of mention.

In 1960, Horace Mann Bond, the noted African-American educational researcher, studied the relationship between socio-economic status and the awarding of National Merit Scholarships. His findings revealed a pronounced skewing of awards toward higher SES students, prompting him to ask whether we have "developed a class system that is almost as fixed and immutable as that long established in Western European social hierarchies" (1960, p. 117). In the same anthology on gifted education in which Bond's paper appeared, Martin D. Jenkins, another prominent African-American educator, felt compelled to point out that mean differences in the IQs of Whites and Blacks did not imply that no 'superior cases' would be found among the latter group, nor did it mean that African-Americans were lacking in "the ability to participate in the culture at the highest level" (1960, p. 111; see Kearney & LeBlanc, 1993, for more about the work of Bond, Jenkins, and other 'forgotten pioneers' in the study of gifted African-American children).

### *Contemporary Indicators of the Under-representation of Economically Disadvantaged and Minority Children*

Current data suggest that the under-representation of economically disadvantaged and minority students in gifted programs has not disappeared. For example, the National Educational Longitudinal Study conducted by the U.S. Department of Education (1991) revealed that eighth grade students whose families' socio-economic status placed them in the top quartile of the population were about five times more likely to be in programs for gifted students than were students from families in the bottom quartile. Moreover, almost half of the eighth grade students identified as gifted and placed in gifted programs were from families in the top SES quartile, whereas about 9% were from the bottom quartile.

Ford & Harris (1999) used data from 1978 through 1992 to compute indices of under-representation and over-representation of certain groups by comparing

<sup>1</sup> Teachers College, Columbia University, USA.  
E-mail: borland@exchange.tc.columbia.edu

<sup>2</sup> Teachers College, Columbia University, USA.  
E-mail: lrw22@columbia.edu

their representation in the general population with their representation in gifted programs. Their data show that Hispanic Americans were under-represented by 24% in 1978 (accounting for 6.8% of the school population but only 5.15% of students in gifted programs) and by 42% in 1992. American Indians were under-represented by 62% in 1978 and by 50% in 1992, and the indices for African Americans were 33% and 41% respectively.

The serious and destructive consequences of this state of affairs can be illustrated in the form of a syllogism that we think is valid. Take the two following premises:

- Students typically derive at least some benefits from being placed in gifted programs, benefits that are realized in school and later in life
- Gifted programs disproportionately serve white middle- and upper-middle-class students

If these premises are true, and we believe they clearly are, the following conclusion is a logical necessity:

- Therefore, gifted programs are serving to widen the gap between society's 'have's' and 'have-not's' and between White and minority families.

The existence and the consequences of under-representation are not in doubt. What is less certain is why the problem exists, a question to which we will now turn.

### **Possible Causes of the Problem of Under-representation**

It is useful to distinguish between those causes of under-representation over which we have an appreciable degree of control and those over which we do not. Among the latter, we will identify conditions in the larger society and, among the former, practices in the field of gifted education. This is a bit of a simplification if one views education, including gifted education, as an instrument for social change, but for purposes of discussion, we will maintain this dichotomy. Let us first examine factors outside the field of gifted education.

#### *Social and Cultural Factors*

Poverty, racism, class bias—inequity in all of its ugly forms—are malignant and insidious forces that can damage people, and children are especially vulnerable. Thus, a child who is born into poverty and experiences the consequences of racism for the first five years of his or her life is likely, whatever his or her innate capacity for academic achievement, to enter kindergarten at a disadvantage educationally. In attempting to understand the underachievement and corresponding under-representation in gifted programs of children from certain groups, we sometimes lose sight of the simple and undeniable fact that such things as poverty hurt all but the most resilient children in ways that can

deny them their basic rights in our schools and our society.

How this translates into academic under-achievement and under-representation in gifted programs is a difficult question. Descriptive data are plentiful. For example, Natriello, McDill & Pallas (1990) list five "key indicators associated with the educationally disadvantaged . . . [that are] correlated with poor performance in school" (p. 16). These are: (a) being Black or Latino, (b) living in poverty, (c) living in a single-parent family, (d) having a poorly educated mother, and (e) having limited English proficiency. Useful as this might be, these data are correlational rather than explanatory, so we have to turn elsewhere for possible insights into how what Natriello et al. refer to as 'educational disadvantage' comes about.

*The work of Ogbu and Fordham.* John Ogbu (e.g. 1978, 1985, 1992) and Signithia Fordham (e.g. 1988, 1991; Fordham & Ogbu, 1986) have provided a useful theoretical framework for investigating the causes and mechanisms of educational disadvantage. Briefly (see Borland, Schnur, & Wright (2000), for a more detailed synopsis), Ogbu's explanation rests on a distinction between 'voluntary minorities', those whose minority status results from voluntary immigration in search of a better life, and 'involuntary minorities', such as African-Americans in the U.S., who were originally brought to this country against their will, denied assimilation into the mainstream, and relegated largely to menial occupations. It is the latter group who most acutely and persistently experience educational disadvantage and, as a result, under-representation in gifted programs.

Although voluntary-minority children may initially experience school difficulties, they do not typically fail generation after generation as many involuntary-minority children do. According to Ogbu, this is because, whereas both voluntary and involuntary minorities experience *primary cultural differences*—differences in language, religious practice, dress, child rearing that existed before they came to the United States—involuntary minorities also experience what Ogbu calls *secondary cultural differences*, which arise in reaction to negative contacts with the dominant culture and serve as "coping mechanisms under 'oppressive conditions'" (Ogbu, 1992, p. 10). Whereas voluntary minorities see primary cultural differences as barriers to assimilation that must be overcome, involuntary minorities use secondary cultural differences as protectors of their very identity and "have no strong incentives to give up these differences as long as they believe they are still oppressed" (Ogbu, 1992, p. 10).

One possible form secondary cultural differences can take is *cultural inversion*, "the tendency . . . to regard certain forms of behavior, events, symbols, and meanings as inappropriate . . . because these are characteristic of White Americans" (Ogbu, 1992, p. 8).

In other words, denied opportunities to assimilate into the mainstream culture, involuntary minorities develop a subgroup identity based on values, attitudes, and behaviors that are directly oppositional to those of the White culture. Socializing children thus involves teaching behaviors and values discrepant from those of the mainstream culture, and sanctions are often applied to those who appear to embrace the values and behaviors perceived as being typical of White America, such as employing standard English or striving for academic achievement. Clearly, cultural inversion would militate against involuntary-minority parents desiring placement in gifted programs for their children and could be a cause of the under-representation under examination here.

This creates a dilemma for potentially gifted involuntary-minority students, which Fordham (1988, 1991); Fordham & Ogbu, 1986; refers to as the “burden of acting white.”

Learning to follow the standard academic practices of the school is often equated by the minorities with . . . “acting white” while simultaneously giving up acting like a minority person. School learning is therefore consciously or unconsciously perceived as *a subtractive process*: a minority person who learns successfully in school or who follows the standard practices of the school is perceived as becoming acculturated into the white American frame of reference at the expense of the minorities’ cultural frame of reference and collective welfare (Fordham & Ogbu, 1986, pp. 182–183).

The quandary faced by gifted students from involuntary-minority groups can be a painful one: either adopt attitudes and behaviors that, although facilitative of school success, serve to alienate one from friends and culture, or maintain loyalty to friends and culture by sacrificing one’s prospects for academic and vocational success.

Research by Ford (1992, 1993, 1996) suggests that this is indeed a significant problem for some bright involuntary-minority students. In her sample of 148 African-American fifth and sixth graders identified as either gifted, above-average, or average in academic ability, 97 “reported exerting low levels of effort in school” (1992, p. 134). This included 38 of the 48 gifted students, despite their endorsement of what Ford calls the “American achievement ideology” (p. 11).

The work of these researchers suggests that there is a powerful array of forces that work to lower the academic achievement of involuntary-minority children. Fordham & Ogbu (1986), referring to African-American children, summarize these as follows:

The low school performance of black children stems from the following factors: first, white people provide them with inferior schooling and treat them

differently in school; second, by imposing a job ceiling, white people fail to reward them adequately for their educational accomplishments in adult life; and third, black Americans develop coping devices which further limit their striving for academic success. (p. 179)

Clearly, the under-representation of economically disadvantaged children, especially those from racial and ethnic minority groups, in programs for gifted students is a problem that, in Ford’s words, is “complex and perplexing . . . requiring movement away from traditional theories and paradigms, including those which hold that under-achievement results only from a lack of motivation to achieve” (1992, p. 134). Moreover, it is part of a larger problem, the failure of our educational system to educate economically disadvantaged and minority students, that is the product of persistent structural inequities in our society.

#### *Factors Within the Field of Gifted Education*

Although the under-representation of economically disadvantaged and minority children in gifted programs is in part a function of inequities in our society, we also believe that beliefs and practices within the field of gifted education have contributed to the problem. Among the factors within the field that contribute to the problem are the following.

*Conceptions of giftedness.* Giftedness is context-specific and socially constructed (see, for example, Sapon-Shevin, 1994; Borland, 1996). It is not a fact of nature but rather a concept that was created by human beings because it was thought to be necessary. As a construct, giftedness is inevitably tied to notions of excellence and potential, and these ideas of excellence reflect the society in which individuals live. In fact, some writers, such as Tannenbaum (1983, 1986) in his “psycho-social conception of giftedness,” argue that the environment, the social context, is a component of giftedness. In multicultural societies, conceptions of excellence and giftedness are likely to be shaped by the values of the dominant culture or subculture. In the U.S., for example, intellectual and academic giftedness, as it has traditionally been understood and operationalized, has largely been White middle- and upper-middle-class giftedness.

The point is that giftedness as a concept, as a label in the schools, and ultimately as a descriptor of certain adults is likely to reflect the values and strengths of the dominant culture and to slight those of other cultures, especially those of involuntary minorities who employ such secondary cultural differences as cultural inversion as a means to define and protect their identities. Thus, we would argue that *giftedness*, the very notion that gave rise to this book, has embedded in it the basis for the under-representation of certain groups outside the mainstream of any culture in which the concept is employed.

One need not view this as reflecting malign intent, although some do. According to social or cultural reproduction theory (see, for example, Katz, 1975; Apple, 1982; Spring, 1989), society's inequities, among them racism and wide disparities in wealth, work to the benefit of a wealthy and powerful elite. Society is structured to maintain the dominance of those in power and to perpetuate the subordinate status of those in the underclass, and social institutions, such as the educational system, are designed to perpetuate inequities that benefit the elite by reproducing, in the educational system, the hierarchical stratification found in the larger society.

One way the schools serve to maintain the status quo and the current power structure, according to social reproduction theory, is by denying an adequate education to the poor and the non-White. Gifted education is seen by some as an instrument of social reproduction and one of the means whereby schools perpetuate racism and economic injustice. Sapon-Shevin (1994) writes, "Whether or not the intention of gifted programs is to reproduce existing economic and racial hierarchies or to produce cultural capital held by an elite group of students, these are in fact the consequences of such a system" (p. 192).

Although we do not believe that gifted education is the result of a conscious intention to perpetuate inequities in society, there remains the nagging question of whether the very concept of giftedness necessarily leads to or reinforces racial and economic inequities, whether it might be impossible to conceptualize and operationalize the distinctions at the heart of the concept independent of such factors as race, ethnicity, and SES. The most pessimistic answers to that question hold some troubling implications for the field of gifted education.

*Identification practices.* That White middle-class children are identified as gifted in proportions that exceed their proportion in the general school population is a fact of educational life in the U.S. In part, this is a consequence of the ways we have traditionally identified students as gifted, which are themselves rooted in the values of the white middle class. For example, IQ tests have traditionally played a major role in identifying gifted students. Although no-one in the field of gifted education of whom we are aware advocates using these tests as Terman (1925) and Hollingworth (1942) used them, such tests and other measures that correlate substantially with IQ are still widely used in the schools to identify gifted students.

Standardized tests can play an important role in the equitable identification of gifted students (see, for example, Borland, 1986; Pendarvis & Howley, 1996). However, unless we also use non-traditional methods for identification (Borland & Wright, 1994), inequities will be inevitable. Furthermore, our traditional conception of identification as a method whereby we separate

the gifted students from the rest of the student population has, despite some challenges (e.g. Renzulli, Reis & Smith, 1981), continued to dominate our thinking. As long as this is the case, we may be faced with the problem we address in this chapter.

### **Some Thoughts About How to Address the Problem of Under-representation**

Without pretending to have the answer to the question of how to remedy the problem of under-representation, we will present some of what we learned through our work in Project Synergy at Teachers College, Columbia University. To begin our discussion, let us take the two topics we identified above as being endogenous to the field of gifted education.

*Conceptions of giftedness.* We need to rethink giftedness as a concept and to do so radically, to go to the root of the concept and examine what it means, what it connotes and implies, and what value it actually brings to our field. At the very least, we need to examine our conceptions of giftedness in order to identify whether and how they might lead to the inequities we discuss above. Take as an example Renzulli's three-ring conception of giftedness (e.g. 1978, 1986), probably the most influential conception of giftedness in recent times. Renzulli challenged some well-entrenched, fundamental assumptions about giftedness, including the primacy of high levels of general ability, a legacy of Terman, Hollingworth, et al. This alone makes the definition a significant contribution to our literature. Yet, even this definition, in which giftedness is conceived of as an interaction among above-average ability, creativity, and task commitment, can, contrary to its author's intention, be operationalized in a manner that reinforces social inequities.

Creativity and task commitment are necessarily assessed subjectively, that is, without the use of standardized tests, since valid standardized measures of these constructs do not exist. This is not necessarily a liability; in fact, we strongly advocate the use of subjective measures in gifted education (see, for example, Wright & Borland, 1993; Borland & Wright, 1994). But problems can occur when any conception is applied in the practical sphere. For example, the New York City Public Schools serve 1.1 million students in a system in which the teachers are predominantly White and middle class and the students are not. It is not difficult to conceive of how conceptions of task commitment might be quite discrepant in the cultures in which, on the one hand, the majority of teachers and, on the other, the majority of students live. Teachers might, without any malign intent, conceive of this construct in a manner that predisposes them to see it in children culturally like themselves and not to see it in students unlike themselves.

If this can happen with a conception of giftedness that breaks with a prevailing psychometric tradition

that favors White middle-class students, few if any conceptions are immune to this problem. This seems to leave us with two options. The first is to attempt to develop conceptions of giftedness that are either culture-fair or equitably multicultural. This may prove to be as difficult as the attempt to develop culture-fair tests has been.

A second approach led one of us a few years back to “think the unthinkable: that there might be effective gifted education without gifted programs” (Borland, 1996, p. 144). Perhaps it is time to ask an even more radical question: Can there be effective gifted education without gifted children? By this, we mean to ask whether we can accomplish the goals that gave rise to the field of gifted education without identifying children as gifted or even having recourse to the construct of giftedness at all. This latter course of action would constitute nothing short of a revolution in the field of gifted education. It would, no doubt, be strongly resisted by many of our colleagues, but as a thought experiment it could be a productive exercise. We suggest that it is once again necessary to think the unthinkable.

*Identification practices.* We would like to propose two possibilities for dealing with problems of inequity deriving from identification practices. The first of these is to work within the traditional conception of identification as a sorting process and to make the process more equitable and sensitive to diverse expressions of giftedness. Since we are most familiar with our own work in Project Synergy, we will use that as an example (see Borland, 1994; Borland & Wright, 1994). In this project, we learned that certain features of an identification process can make it more effective for identifying economically disadvantaged students. They include:

- a post-positivistic approach to assessment (see Borland, 1990), including the use of observation and other forms of the ‘human instrument’ (Lincoln & Guba, 1985);
- a focus on ‘best performance’ (Roedell, Jackson & Robinson, 1980) instead of averages of scores and ratings;
- curriculum-based assessment and other forms of ‘authentic assessment’ instead of, or in conjunction with, standardized measures;
- portfolio assessment (Wright & Borland, 1993);
- dynamic assessment, based on the work of Vygotsky (e.g. 1978) and Feuerstein (e.g. 1980), in which assessment is carried out in Vygotsky’s “zone of proximal development”;
- open-ended teacher referrals instead of checklists;
- a case-study approach to identification that relies on human judgment instead of a mechanical approach such as combining scores, which is characteristic of a matrix;

- conceiving of identification as a process, not an event; that is, making the identification process a long-term one, extending at least over a period of months.

We strongly believe that modifying identification procedures as we did in Project Synergy and has been done in other Javits Grant projects (e.g. Baldwin, 1996; Coleman, 1994; O’Tuel, 1996; Feiring, Louis, Ukeje & Lewis, 1997) can improve our field’s performance with respect to equity. However, there is a second possible direction for the field, and this is the course of action we suggested above: the possibility of gifted education without gifted students, or the concept of ‘the gifted student’.

It is often said that, in an ideal educational world, special education, including gifted education, would not be necessary because curricula would be sufficiently responsive to individual differences to make separating children into exceptionality categories unnecessary. We have worked with school districts to move in this direction by helping them plan and implement programs that combine school-wide enrichment; flexible grouping across grade levels in major subjects; and, for a very few truly exceptional students, individual educational plans. The result is a form of gifted education that does not look like traditional gifted education and that requires little in the form of traditional identification, save for those few students who require individual plans (whose identification involves a process that begins with pre-kindergarten screening and continues for two or three years).

In many ways, identification is at the crux of the problem of under-representation, for this is the process whereby more students from some groups and fewer children from other groups are designated as gifted. It seems to us that a major decision has to be made if we do not want to live with the inequities that have plagued the field since its inception. Either we have to make our practice equitable by modifying the way we do the things we have always done, or we have to give these things up while still hewing closely to our core values. In other words, we need to determine whether we can have gifted education, that is, its fundamental goals, without not only gifted programs as we have traditionally known them but without gifted children, labeled as such, as well.

If we give up the processes of conceiving of giftedness as a trait, or even state, possessed by some and not others and also forego the process of sorting children into ‘gifted’ and ‘not gifted’ groups and instead attempt to achieve the goals inherent in the practice of gifted education through curriculum reform and more creative administrative arrangements such as flexible grouping, large-scale equity problems in education will not disappear. However, the problem of under-representation that we are analyzing here would become a moot point, for program placement, the

activity that gives rise to under-representation, would no longer be a concern. Discrepancies in educational achievement would and should, of course, continue to be a concern. However, addressing these as issues of educational achievement instead of gifted or non-gifted status strikes us as a slightly, but significantly, more tractable matter for educators.

*Curriculum.* We will briefly address two issues related to curriculum for gifted students that are germane to the problem of under-representation. The first is the role multicultural education can play in gifted education. Ford & Harris (1999) advance the perhaps controversial idea that gifted education and multicultural education are complementary and point to some practical steps educators can take to effect this synthesis. To the extent that such educational streams as gifted education and multicultural education are seen as having a potential confluence, the goal of remedying the under-representation of economically disadvantaged and minority children in gifted programs will seem less remote.

The second approach derives from our work in Project Synergy. Working with kindergarten children in a severely under-resourced school in Central Harlem, we quickly became aware of two things. The first was that there were potentially gifted students in this school just as there are in any other. The second was that the students were not ready academically for placement in gifted programs. Our approach was to implement what we called 'transitional services', curriculum designed to help young students identified as potentially gifted develop their potential so that subsequent placement in gifted programs would be successful and appropriate. Such a curriculum need not be terribly elaborate. In Project Synergy, the emphasis was on traditional skills of reading, writing, and mathematics. We employed a diagnostic-prescriptive model, along with some cultural enrichment, work on thinking skills, and help developing academic 'meta-skills', behaviors and attitudes that seem to be part of the tacit knowledge of successful students. Parent education was another important emphasis.

We think the concept of transitional services has potential in the field of gifted education for students who have not had the nurturance given to students from more economically favored circumstances. In cases where the only alternatives seem to be benign neglect or placement in a demanding sink-or-swim environment, the effort involved in developing transitional services curricula may be amply repaid. This does not mean that the gap between potentially high achieving poor and minority children and their high achieving age peers would necessarily be eliminated, for we are not advocating that the latter mark time while the former catch up. 'Catching up' is not our concern; the development of potential that is too often frustrated by inequities in our society and our schools is.

### Some Final Thoughts

In this chapter, we have tried to describe the extent of the problem of the under-representation of economically disadvantaged and minority children in gifted programs, to discuss some of the forces contributing to the problem, and to suggest some measures that might be palliative, if not curative. It is our hope that the problem can be addressed and substantial progress can be made. This should be a major priority for the field of gifted education, both as a matter of educational effectiveness and a moral imperative. However, we also need to confront the troubling possibility that a complete resolution of the problem may not be possible.

The philosopher Isaiah Berlin, in an essay entitled 'The Pursuit of the Ideal' (1990; see also, Gray, 1996), advances his notion of 'value pluralism', which, we believe, has relevance here. This is the idea that we might not be able to attain a perfect state in which all goods, all desirable outcomes, are realizable. Some goods, Berlin argues, may be incompatible or incommensurable. That is, *A* may be a good, a desirable, even necessary thing; so, too, might *B*, which is equal in importance to *A*. But it may be impossible for both *A* and *B* to co-exist, for them both to be realized.

Berlin writes, "Values may easily clash within the breast of a single individual; it does not follow that, if they do, some must be true and others false" (p. 12). That is, contrary to what many philosophers, at least since the time of Plato, have argued, there may be no perfect system, no ideal world in which the competing claims of various desirable but incompatible outcomes can be realized. As Berlin argues, "The notion of the perfect whole, the ultimate solution, in which all good things coexist, seems to me to be not merely unattainable—that is a truism—but conceptually incoherent" (1990, p. 13).

It occurs to us to ask whether striving for a world in which the goals of both gifted education and perfect equity are pursued is, in Berlin's sense, a striving for that which is conceptually incoherent and, therefore, impossible. Might it be the case that, in any multicultural society in which there are discrepancies in socioeconomic status, the concept of giftedness and the practice of gifted education inevitably lead to the under-representation of certain groups of individuals and obviate the very possibility of equity?

This is a troubling thought. However, since we have been urging our readers to think the unthinkable, we feel obligated to suggest thinking what may be the most unthinkable thing of all within our field. And this is the possibility that two essential, core values—pursuing the goals inherent in the practice of gifted education and striving for racial, ethnic, and socioeconomic equity—may be incompatible. We may be able to realize one or the other, but not both.

This is, in essence, the question Gardner (1961) confronted in his book *Excellence: Can We Be Equal and Excellent Too?* Gardner raised the issue and expressed optimism over the possibility of a resolution, but he did not show how it could be effected. His concluding line, "But who ever supposed it would be easy?" (p. 161) is certainly more optimistic than the response Berlin's idea of value pluralism suggests: "It is not only far from easy, it is impossible."

Perhaps Berlin was wrong, or, if he was not, this may not be one of those situations in which seemingly competing goods are truly incommensurable. And perhaps, until it can be convincingly demonstrated that excellence and equity are, in some ways relevant to the practice of gifted education, mutually antagonistic, we need to proceed as if they were not. That is, we should not give up on either good, we should strive both for excellence and for equity. But we need to consider the disturbing possibility of their incompatibility and, if all evidence suggests that, in this world at least, incompatible they are, we need to make some extremely difficult choices.

# Counseling Gifted Students<sup>1</sup>

Nicholas Colangelo\* and Susan G. Assouline†

## Introduction

Educating gifted students has focused mainly on meeting their learning needs. Counseling needs, while long recognized, are a relatively recent emphasis. Over the years there have been two main (and conflicting) views regarding psychological well being of gifted students (Neihart, 1999). One view is that gifted children are generally very well adjusted; at least as well adjusted as the general student population. In light of this view, there is little need for specialized school counseling for gifted students. Essentially, what gifted students need most is the typical counseling that is available in schools and their needs for counseling are not dependent on their 'giftedness' but on whatever aspects of their personalities may need attention.

The other view is that giftedness brings with it an array of intrapersonal and interpersonal issues that are unique to their 'giftedness'. Gifted students by their very advanced cognitive abilities and intensity of feelings deal with issues about self and others in ways that are unique from the general population and therefore require specialized understanding. Interpersonally, gifted students are handed the task of adjusting to a peer culture that is often ambiguous if not downright hostile to those with intellectual talent. In this second view, counseling for gifted is seen as a specialty. Counselors need to be aware of those unique needs of gifted students as they try to navigate the challenges of their development and the challenges of an environment of confusing and 'mixed' messages. The assumption in this view is that while the majority of gifted students will and do make satisfactory psychological adjustment, there is a sizeable minority

that are psychologically 'at risk' and need counseling that is focused on their needs.

Our contention is that the latter view is more helpful and accurate. From our experience and research, gifted students do have recurring and significant counseling needs based on their 'giftedness'. The focus of this chapter is on counseling needs of the gifted student and the role of the school counselor in addressing those needs. We recognize that counseling gifted students can take place in private practice and community mental health centers; however, our focus will be on the counseling that can be done in a school setting.

## Historical Overview

A brief historical overview of counseling with gifted students will help set the present-day context. The gifted-child movement in the United States can be traced back to Lewis M. Terman, whose pioneering longitudinal study of 1,528 gifted children formed the project titled *Genetic Studies of Genius* (Terman, 1925; Burks, Jensen & Terman, 1930; Terman & Oden, 1947, 1959). The Terman studies grounded the study of giftedness in an empirical and psychometric tradition. Also, the work dispelled negative myths and traditions regarding the gifted. For example, Terman and his colleagues showed that gifted children were physically superior and psychologically and socially more stable than their intellectually average peers. The studies indicated that giftedness was a 'positive' and initially distracted professionals from issues of a psychological nature.

Because Terman's studies seemed to provide evidence that concern for gifted students' social/psychological needs was not necessary, any initial focus on counseling for gifted students was essentially derailed. However, since the sample from Terman's seminal studies is no longer considered representative of the broader gifted population, it is no longer valid to assume that there is a general absence of concern for the social-emotional well-being of the gifted student.

Terman's sample was identified by use of the Stanford-Binet intelligence test, and his sample was nearly exclusively white and middle-class youngsters (Holahan & Sears, 1995). The original group recommended for the Stanford-Binet testing was picked by teachers, and so some teacher biases probably entered

---

\* The Connie Belin & Jacqueline N. Blank International Center for Gifted Education and Talent Development, University of Iowa, Iowa City, USA.

† The Connie Belin & Jacqueline N. Blank International Center for Gifted Education and Talent Development, University of Iowa, Iowa City, USA.

into the selection process even before the standardized testing. Further, although Terman erased a number of myths, he created others, most notably the myth that gifted children are uniformly well adjusted and therefore do not need counseling services. Thus, counselors and those in related professions were not an integral part of gifted education during its early development (Webb, Meckstroth, & Tolan, 1982; Kerr, 1986).

Leta Stetter Hollingworth (1926, 1942) was the first to contribute evidence indicating that gifted children do have social and emotional needs meriting attention. Hollingworth also emphasized strongly that the regular school environment did not meet the educational needs of the gifted. Rather, she wrote that the school environment was more likely to lead to apathy with these youngsters. She anticipated some of the emotional difficulties and peer problems that receive attention today. Especially, noting that there is often a gap between a gifted student's intellectual and emotional development, she stated, "To have the intellect of an adult and the emotions of a child combined in a childish body is to encounter certain difficulties" (Hollingworth, 1942, p. 282).

The 1950s witnessed some major attention to counseling gifted students and the establishment of research and guidance programs. John Rothney, a counselor educator, founded the Wisconsin Guidance Laboratory for Superior Students (University of Wisconsin-Madison), which was headed by Rothney and later by Marshall Sanborn. The Guidance Institute for Talented Students (GIFTS) was headed by Charles Pulvino, followed by Nicholas Colangelo and then by Philip Perrone (Colangelo & Zaffrann, 1979).

John Curtis Gowan was a major force from the 1950s to 1970s in promoting counseling services for the gifted. A. Harry Passow and his students Abe Tannenbaum and Miriam Goldberg founded the Talented Youth Project in 1954 which had a strong counseling component. The 1960s and 1970s also witnessed increased sensitivity to issues dealing with gifted women, minorities, and disadvantaged students, and to the counseling needs of the gifted.

The 1980s saw the establishment of the Supporting the Emotional Needs of Gifted (SENG) program by James T. Webb at Wright State University after the suicide of Dallas Egbert, a highly gifted 17-year-old. SENGL has continued its focus on addressing the counseling and psychological needs of gifted students. The issues of depression and suicide among the gifted have continued to expand with the work of James Delisle at Kent State University (e.g. Delisle, 1992).

In 1982 Barbara Kerr established the Guidance Laboratory for Gifted and Talented at the University of Nebraska-Lincoln, to extend the work of both GIFTS and SENGL (Myers & Pace, 1986). Linda Silverman (1993), a psychologist, established the Gifted Child Development Center at Denver, Colorado. In 1988, The University of Iowa established the comprehensive

Connie Belin National Center for Gifted Education (renamed The Connie Belin & Jacqueline N. Blank International Center for Gifted Education and Talent Development in 1995) with Nicholas Colangelo as director. The Belin-Blank Center has a strong focus on personal counseling, career guidance, family counseling, and psychological assessment. The clinical programs at the Belin-Blank Center are headed by Susan Assouline, associate director and school psychologist.

In a historical overview of counseling gifted students, Karen St. Clair (1989) divided counseling into several areas which we find useful.

- (1) Early 1900s—recognition of the counseling needs of gifted students focusing on the work of Terman and Hollingworth.
- (2) The 1950s—a non-directive approach to counseling the gifted student which acknowledged the influence of Carl Rogers (Rogers, 1951) to the entire counseling profession.
- (3) The 1960s—the beginning of counseling the gifted in schools where the role of the school counselor was emphasized in the development of all students with some special attention to the gifted.
- (4) The 1970s—program development for counseling gifted students emphasized a full fledged program of counseling in schools focusing not only on counseling sessions, but counseling programs, evaluations, and research related school counseling.
- (5) The 1980s—diversity in counseling the gifted indicated a decade of special issues in counseling including focus on underachievement, females, minority students, and stress. This period was also characterized by diversity in terms of models and approaches to counseling.

To St. Clair's review we add the following:

The 1990s—counseling gifted-special-needs students provided a strong emphasis on gifted students as special-needs learners. There was a focus on gifted students who were double labeled, e.g. gifted/learning disabled. There was also a focus on providing programs (counseling and curriculum) that matched the dual exceptionalities of the students, (see for example Cash, 1999). A focus on families and sexual identity issues were also important trends in this decade.

The year 2000 and beyond—in the next decade we anticipate a sharper focus on ethics and moral issues as well as the continued focus on the 'emotional intelligence' of students. In addition there will be an expanding focus on rural issues and on international issues as the vision of giftedness will include a global perspective.

### **Self-Concept**

The interest in self-concept, which by no means was initiated in the 1990s, has seen a very powerful revival

during that decade. Almost everything 'good' in school life seems related to a positive self-concept and almost all that is 'at risk' has at least an aspect of negative self-concept associated with it. Robyn Dawes (1998) indicated that pop psychology associates positive mental health with self-esteem (i.e. self-concept). His brief review indicates that there are a number of destructive behaviors that are done by adolescents and adults who seem to have quite positive evaluations of themselves. His insightful comments at least give cause to consider that simply having high self-esteem/self-concept does not assure prosocial behavior and that we must consider that students with high (positive) self-concepts may also perform actions with negative consequences.

The self-concept construct has deep historical roots in psychology and education. The self-concept can be viewed as a "powerful system of cognitive structures that is quite likely to mediate interpretation of and response to events and behaviors directed at or involving the individual" (Nurius, 1986, p. 435). The definition of self-concept has evolved from a "collection of self-views" (e.g. Snygg & Combs, 1949; Rogers, 1951) to general good and bad feelings about oneself (Shavelson, Hubner & Stanton, 1976; McGuire, 1984) to recent theory and research on operationally defining the structures and contents of the self-concept (Nurius, 1986; Marsh, 1990; Colangelo & Assouline, 1995). Neihart (1999) states that self-concept is the collection of ideas that one has about oneself, an essential component of what is usually called personality.

Self-concept of gifted youngsters has received considerable attention in the past two decades. Neihart (1999) indicates that a number of studies have concluded that there are no differences between gifted and non-gifted students; however, a number of studies have concluded that there are differences in favor of gifted students particularly when measuring assessment of one's academic abilities. These studies typically have investigated: (1) how gifted and average children's self-concepts compare (Karnes & Wherry, 1981; Kelly & Colangelo, 1984; Loeb & Jay 1987; Hoge & Renzulli, 1993); (2) whether self-concept is a developmental construct (Karnes & Wherry, 1981; Harter, 1982; Hoge & McSheffrey, 1991; Marsh, 1992, 1993; Hoge & Renzulli, 1993); and (3) how programming affects a child's self-concept (Maddux, Scheiber & Bass, 1982; Kelly & Colangelo, 1984; Loeb & Jay, 1987).

Self-concept and giftedness represent complex constructs, and the study of each is made more difficult by theoretical controversies within each field. For example, the developmental nature and processes of self-concept have been debated (Ketcham & Snyder, 1977; Karnes & Wherry, 1981; Harter, 1982). Additionally, there are concerns about the reliability and validity of measures of self-concept (Wylie, 1989;

Marsh, 1990, 1993, 1994). In the area of gifted education, the question of uni-dimensionality versus multi-dimensionality has also permeated almost every aspect of the field.

Our research lends credibility to the multi-dimensional nature of self-concept. In a research study (Colangelo & Assouline, 1995) investigating the self-concept of 563 gifted students spanning grades 3–11, we found support for the general notion that the overall self-concept of gifted students is positive. However, there were peaks and valleys across the grade levels and the various domains as measured by the Piers-Harris Children's Self-Concept Scale. Most importantly for school counselors were the following findings:

- (1) General self-concept scores were high for elementary, middle, and high school students; however, high school students had the lowest scores. High school girls in particular had the most significant drop in self-concept scores.
- (2) As gifted students progress in school they become more anxious and feel more isolated.
- (3) The lowest scores of the 563 students in the study were found in the domains of interpersonal skills and self-satisfaction.
- (4) The highest scores were in the domains of intellectual and school status.

Closely related to self-concept is the attitude that gifted students have toward their own giftedness. Three books—*On Being Gifted* (American Association for Gifted Children, 1978), *Gifted Children Speak Out* (Delisle, 1984), and *Gifted Kids Speak Out* (Delisle, 1987)—present testimonials from gifted children describing the impact of giftedness on their lives.

One conclusion that can be drawn from these testimonials is that these children have mixed feelings about their giftedness. Research has provided some confirmation of this ambivalence. Colangelo & Kelly (1983) found that while gifted youngsters were positive about their being labeled gifted, they perceived non-gifted peers and teachers as having negative views of them. A study by Kerr, Colangelo & Gaeth (1988) indicated that the attitude of gifted adolescents toward their own giftedness was multifaceted. Adolescents reported that being gifted was a positive in terms of their own personal growth and in terms of academics. In terms of social peer relations, however, they reported it to be a negative. In a partial replication of the Kerr et al. study, Monaster, Chan, Walt & Wiehe (1994) supported the finding that attitudes toward giftedness are multifaceted. In addition, Monaster and colleagues found that those who knew the gifted child well had positive attitudes toward the child, and that attitudes became more negative toward 'giftedness' as respondents were removed from personal knowledge of a gifted youngster.

The Kerr et al. and Monaster et al. findings are very relevant for school counselors because the issues focus on human interaction. In individual counseling sessions, counselors can discuss issues such as: What does it mean to be gifted? What do I like about being gifted? What do I not like about being gifted? If I were not gifted, what would be better for me? If I were not gifted, what would be worse for me?

### Career Counseling with Gifted

When gifted students are about to graduate high school and begin to plan for a college and career, parents and educators often get involved to ensure that the student 'does not waste the gift.' From our experience with this phenomenon, not wasting the gift translates into 'making a decision(s) that is reasonable to the adult.' Without articulating specifics, it seems there are a number of adults who believe certain careers are 'worthy' of a gifted student, and that others are not. Medical doctor, lawyer, engineer and physicist typically fall into the category of worthy, while elementary/secondary school teacher, social worker, school counselor, and nurse typically fall into a less worthy category.

Career planning for high ability students has not always been smooth (Kaufmann, 1981; Kerr, 1985, 1991, 1998). Gifted students do not always know what they want to do for the "rest of their lives" and while they may have the academic credentials to succeed in classes, this does not mean that they have the information to 'plan' for a career. Ability and ambition do not always translate into planned or purposeful action.

### Multipotentiality

The most written about aspect of the unique career needs of gifted students is 'multipotentiality'. As the term implies, it refers to individuals who have diverse talents (and interests also) and who could 'succeed' at a high level in a number of different fields. The problem is how to make a decision, how to choose a path, from so many realistic possibilities? While this may seem a problem one would gladly 'suffer' it is a significant problem for gifted students. "Multi-potential young people may anguish over an abundance of choices available to them during career planning unless appropriate interventions are available" (Rysiew, Shore & Leeb, 1999, p. 423). The most useful definition of multipotential comes from Frederickson & Rothney (1972), "the ability to select and develop any number of competencies to a high level" (p. vii). Without the stipulation of developing competencies at a very high level the concept of multipotentiality loses any sense of meaningfulness. Most educators in the field of gifted education adhere to the belief of multipotentiality. While there has been some discussion that the term should be reserved for abilities and not interests (see Rysiew, Shore & Carson, 1994), there has been little

disagreement as to the existence and importance of this concept in understanding giftedness.

Where there has been an absence of empirical data supporting the notion of multipotentiality, there have been considerable anecdotal and clinical reports regarding the concept (Rysiew, Shore & Leeb, 1999). The only serious challenge to the usefulness and existence of multipotentiality has come from Achter, Lubinski & Benbow (1996) and Achter, Benbow & Lubinski (1997). These authors "have challenged the utility of the entire notion of multi-potentiality based on their observation of widely varying patterns of specific abilities and interests in a large sample of gifted adolescents, thereby challenging the ubiquity of low differentiation or high flat interest profiles" (Rysiew, et al., p. 424).

Rysiew et al. (1999) outline some of the main problems or concerns in dealing with multipotentiality, especially as it deals with career choices:

- (1) Students find it hard to 'narrow' to a career since they have so many equally viable options.
- (2) Multipotential students also suffer from perfectionism, thus look for the perfect or ideal career.
- (3) Students feel 'coerced' from parents and others to make decisions based on status and high earning potential.
- (4) Students must make commitments which may have long term schooling (graduate, professional) and a delay of independence in terms of earning a salary as well as starting families. These long term 'training' investments are also difficult to change once a student has embarked for several years towards a particular career, even if there are serious doubts about the chosen career path.

Rysiew, et al. (1999) review a number of writings regarding what counselors can do to help multipotential gifted students with career decisions. Among the recommendations are:

- (a) Career is explored as a way of life, a lifestyle rather than a particular job/position.
- (b) One does not have to limit to one career but that there can be career changes as well.
- (c) Use leisure activities as a way to continually develop areas of abilities and interests apart from one's career.
- (d) Use career counseling as a value-based activity, exploring broad categories of life satisfaction.
- (e) Emphasize peer discussions and group work with other multipotential youth so that one can see that he/she is not alone with concerns.

Since 1988, the students selected for the Belin-Blank Center programs have participated in a Counseling Lab for Career Development. This career development program incorporates the recommendations listed by Rysiew, et al. (1999). In particular, the values-based component of the Counseling Lab for Career Develop-

ment has proven highly successful with secondary students.

### Group Counseling

Gifted students are considerably smarter about course work than about themselves. They have the ability to be insightful about themselves, but seldom the opportunity to articulate and share their insights.

Counselors can offer no more powerful tool for the social and emotional growth of gifted students than group counseling. Group counseling is a rich arena that affords students a rare opportunity to share with one another their struggles and questions about growing up and what it means to be 'gifted'. But simply sitting around talking about feelings and values is not enough. Group counseling is a structured situation with a trained leader (e.g. a school counselor) who has knowledge of both gifted youngsters and group dynamics.

#### Why Group Counseling for Gifted Students?

All students grow by having opportunities to discuss feelings and perceptions in an atmosphere of trust and understanding. Also, students need to share with peers. To think of *peers* as one's age-mates trivializes the concept. A peer is more a "soul-mate than an age-mate," someone who understands what you mean, has experienced what you are talking about, and can respond to you. Gifted students seldom have the opportunity to talk to one another about what it means to be gifted or how it feels to understand things that many age-mates cannot seem to grasp. These are subjects that educators do not encourage for discussion, and gifted students are bright enough to know it's best to keep such things to oneself.

Grouping gifted students for the sole purpose of helping them discuss, in a safe and open atmosphere, issues of a more personal and social nature gives them an opportunity to enjoy and grow from their peers. Most of the time gifted students 'hide' who they are (Colangelo, 1991). Group counseling is a situation in which they are encouraged to share themselves with others who understand and accept. We would guess that if gifted students were given a chance to meet as a small group for the purpose of self-discovery, for most of them this would be their first opportunity to share with true 'peers'. If a rationale is needed for group counseling with gifted students, it is that in the course of school life such a situation will not arise naturally.

#### Topics for Group Counseling

A counselor may wonder what topics are useful or of interest to gifted students meeting for group counseling sessions. These students will not find it difficult to generate discussion. In our experience with groups, the challenge is in ending the discussions rather than in starting them.

A counselor needs to set the atmosphere for a group. He or she must be clear on the ethics, purpose, rules, and norms. The overall purpose is for gifted students to be able to talk about themselves and learn about one another in an atmosphere of safety and respect. The following are some stems that a counselor may use in generating discussions:

- (1) What does it mean to be gifted? We have found exciting and varied discussions generated by such a question. Students will see it in different ways. Questions that help elaborate this topic are:
  - (1a) What do your parents think it means to be gifted?
  - (1b) What do your teachers think it means to be gifted?
  - (1c) What do other kids in school think it means?
- (2) How is being gifted an advantage for you? How is it a disadvantage?
- (3) Have you ever deliberately hidden your giftedness? If so, how?

Colangelo (1991) reported on group discussion with gifted students in which they talked about 'deliberate underachievement'—purposely getting lower grades so that their friends would be more accepting of them. Many gifted students will be able to articulate how they make decisions to avoid demonstrating their giftedness.

- (4) How is your participation in this group different from your regular school day?

Colangelo (1991) also reported that students in groups talked about how, "Finally, I can be myself" or "I can say what's on my mind without someone making fun of me or saying I'm a snob."

In studies reported by Colangelo & Kerr (1990) and Kerr & Colangelo (1988), it is obvious that gender and ethnicity are important variables related to giftedness. A variation of questions we have found useful are:

- (5) Would you rather be a gifted boy? Gifted girl? What does it mean to be gifted and Latino? Students will find it stimulating to discuss such issues. Also, they will achieve much better insight into gender and ethnic issues.
- (6) Is there a time in school (elementary, middle, high school) when it is easiest to be gifted? Most difficult? Why? The foregoing questions are by no means exhaustive and they will lead to other related questions and directions.

#### Dynamics and Techniques

The essence of group counseling is to transform students from *spectators* to *participants*. Although there is evidence of the positive effects of being a spectator in a group, its value pales compared to the value of being a participant (Yalom, 1985). To be a

spectator means to observe and listen, but to be only tangentially associated with the topic of discussion. A group is not effective when the primary role of its members is that of spectator.

A counselor can transform spectators into participants by taking opportunities to make any topic of discussion a connector to each group member. Following is a specific example using the concepts of *vertical* and *horizontal* self-disclosures.

*Let's say a student is talking about her feelings about having been labeled gifted.* The counselor could ask her questions to help her elaborate on these feelings: "How long have you felt this way?" "Is it changing at all for you?" "Who knows that you felt this way?" All of these are good questions that help the student talk more about her feelings. These questions lead to what can be called *vertical* self-disclosure (Yalom, 1985) because they help 'build' more information on how the student feels about labeling. As we build this mound of information, the rest of the students in the group are listening (perhaps nodding in agreement), being empathic, and so on. Their role is primarily that of spectator (albeit sympathetic and interested ones) in that they are observing this interaction between the one student and the counselor.

Using the same incident, the counselor could transform the group members from spectators to participants by moving from *vertical* to *horizontal* self-disclosure. Instead of asking for more information on the feelings about labeling, the counselor asks the student, "Who in this group do you think feels the same way you do?" or "Who in this group do you think feels most different from you about labeling?" These types of questions are *horizontal* in that they connect students to one another (Yalom, 1985). The students in the group are no longer simply spectators, listening to one girl talk about labeling. Instead, they are actively involved in their own feelings and perceptions about labeling. In every group there will be countless opportunities to take what a student says and make *horizontal* connections. Every *horizontal* connection makes better use of group dynamics and generates more energy and participation.

The second technique we want to share is not so much focused on transforming spectators to participants as it is on helping students to pay better attention to the processes in their group. At the end of every group session, the counselor can ask one student to "process for the group." What this means is to take the last three to five minutes of the session to articulate to everyone what he or she thought happened in the group. This group process time is an opportunity to share how the group went about its task for the session. This simple technique accomplishes several important tasks. First, over time, it gives each student a chance to share what he or she 'saw' happening in the group. It also offers other students a chance to hear the perspective of one member on what happened during a

session. To paraphrase T. S. Elliot, you can have the experience but miss the meaning. This technique minimizes the possibility of missing the meaning. Second, ending every session with group process time is a good way to summarize the session. Third, the group process time can often be an excellent stem for the start of the next group session. For instance, it is not uncommon in groups we have led to have a student start a session with, "When Bob did group process, he said some things that I saw very differently. I want to talk about how I saw them. . . ." The group session is off and running.

Group counseling is an effective means of helping gifted students in their social and emotional growth. It is rare that gifted students ever have the opportunities for grouping when the primary purpose is personal growth rather than academics. Group counseling is most vibrant when members are *transformed* from spectators to participants. For a more extensive treatment of group counseling with the gifted, see Colangelo & Peterson (1993).

### Counseling with Families

The family has been recognized as a primary and critical component in the development of talent and the success of children in school. Bloom's (Bloom, 1985; Bloom & Sosniak, 1981) seminal work on talent development made a compelling case for the demands on, as well as the influences of, the family on the development of talent. Although research and writings on families of gifted students have increased in the last two decades (see reviews by Colangelo & Assouline, 1993; Moon & Hall, 1998), counseling with families is still an area of exceptional need and challenge.

In the special anniversary issue of *Roeper Review*, it was emphasized that one of the most significant trends in gifted education over the next ten years would be a focus on families (Colangelo, 1988). Although there has been an increase in counseling families, counselors and therapists who work with families of gifted children rarely have expertise in the area of the gifted (Wendorf & Frey, 1985; Moon & Hall, 1998). Their expertise is in family counseling.

A major review of family issues was done by Colangelo & Dettmann (1983). Recently, the major review on family counseling and family therapy has been done by Moon & Hall (1998). A summary of the findings by Moon & Hall (1998) includes:

- (a) Parents of gifted have unique stressors and concerns brought about by the unique cognitive and personality characteristics of gifted children.
- (b) Parenting styles tend to be child-centered, with high expectations for education and achievement, and a value of cultural and intellectual activities.
- (c) While families of gifted children have been found to have general close relationships, with flexibility and bonding, others have been found to experience

stress, disorganization and dysfunctional interactions.

- (d) Moon and Hall discuss that family therapists, while they are experts in family dynamics, do not have the expertise regarding the unique cognitive and affective characteristics of gifted children. With some parents seeking guidance in family issues, family therapists (and school counselors) will need to complement their clinical expertise with knowledge of giftedness so that they can be effective helpers for these parents.

#### *Sibling Relationships and the Label 'Gifted'*

School counselors should anticipate difficulties in families when a child is first labeled *gifted*. It is at this time that the family needs assistance. First, school counselors need to be certain that parents clearly understand why their child has been identified as gifted. Many counselors hold parent discussion groups to clarify this issue. Second, counselors should help families anticipate changes as they attempt to adjust to the label. For siblings, the *gifted* label throws into question their role and their importance in the family.

Cornell and Grossberg (1986) found that in families with labeled gifted children, the non-labeled children are more prone to personality adjustment problems. Grenier (1985) reported increased competition and diminished cooperation by non-labeled siblings (see review by Jenkins-Friedman, 1992; Moon & Hall, 1998).

The good news is that the family will become accustomed to the label and positive adjustments are likely over time. Colangelo & Brower (1987) reported that, after a while, the negative effects of labeling disappear. Counselors can effectively ease the initial strain and disruption by helping the family communicate openly about the gifted label. Also, families simply alerted to likely changes seem better able to take some strain and disruption in stride and thus appear to adjust even more quickly.

#### *Giftedness as a Family Organizer*

In working with families of gifted children, it is fair to ask, "To what extent is any issue simply what all families must confront, and to what extent is this issue unique because of the presence of a gifted child?" Giftedness in many families becomes an 'organizer'—that is, a rationale for understanding behavior and actions (see Jenkins-Friedman, 1992).

In some families, behaviors are tolerated because the parents perceive that "this is how it is with a gifted child," or not tolerated because, "such behavior should not come from a gifted child." The giftedness of a child can structure how parents relate to him or her as well as siblings (Moon & Hall, 1998). Many families feel they must put greater energy and resources into the development of a gifted child's talents. Negatives from such organizers can occur when a family loses

'balance' with regard to the needs of other children. As in any case of exceptionality (e.g. a child with a disability), the 'exceptionality' can organize the energy and resources of a family, at times to the detriment of other aspects of the family.

#### *A Family Counseling Program*

At The Connie Belin & Jacqueline N. Blank International Center for Gifted Education and Talent Development (Belin-Blank Center), we have established a family counseling program to respond to the needs of families with a gifted child. The brief counseling approach lasts a maximum of five to six sessions per family. The focus is on helping the family develop its own strengths in the resolution of issues. Families receive services at no cost, and in return for these services they participate in research related to family counseling.

The majority of families who participated in the Belin-Blank Center Clinic sought services for their gifted child's perceived underachievement. The perception is an important concept in the work that we do with families. In some cases, there was significant underachievement. In others, however, the notion of underachievement was the 'symptom' that initiated the contact with the Belin-Blank Center's Clinic. It was not so much a case of the student underachieving as an issue of expectations.

We have also found that although a child's 'giftedness' may be the stated reason for seeking counseling, there are often other issues within these families that have been subsumed under giftedness (e.g. marital discord, alcoholism, delinquency). When this is the case, the families are referred to a family counselor who can provide longer-term therapy.

#### **Parent-School Interactions**

One of the most important issues confronting school counselors is the parent-school relationship (Dettmann & Colangelo, 1980; Colangelo & Dettmann, 1983, 1985; Moon & Hall, 1998). The underlying issue regarding this relationship is the role the school should take in providing special educational opportunities for gifted students. Colangelo & Dettmann (1982) developed a counseling model conceptualizing four types of parent-school interactions involving gifted students (Fig. 1).

Type I (cooperation) is an interaction based on the attitude by both parents and schools that the school should be active in gifted education. The tendency here is for open sharing of information about the child and cooperation between parents and schools. Typically, the gifted are identified and given special educational opportunities commensurate with their needs. The underlying assumption by both parents and schools is that the most effective way to develop exceptional ability is through overt special educational considerations based upon objective information concerning the

student's learning needs (e.g. honors classes, advanced classes, resource rooms, independent projects, ability groupings, and grade skipping).

Type II (conflict) is an interaction based on conflicting attitudes by (active) parents and a (passive) school regarding the role of the school. Parents believe that their gifted child needs special programming by the school in order to develop his or her abilities. However, the school believes that the typical school curriculum is adequate to meet the needs of all youngsters, including the gifted. Also, it is typical for the school to believe that special programs should be a priority for students with disabilities. The school in this situation feels that

parents are pushy and demand unnecessary attention for gifted youngsters. The parents feel they must be aggressive, or the school will ignore the needs of their child.

Type II interactions are often the most difficult for parents and school. These schools tend to view gifted education as an albatross. Parents tend not to support the school and often blame the school for problems their child may have with boredom or lack of motivation and achievement. Parents sometimes encourage the child not to accept the school's evaluations and requirements (e.g. report card grades, class work) as accurate assessments of his or her abilities.

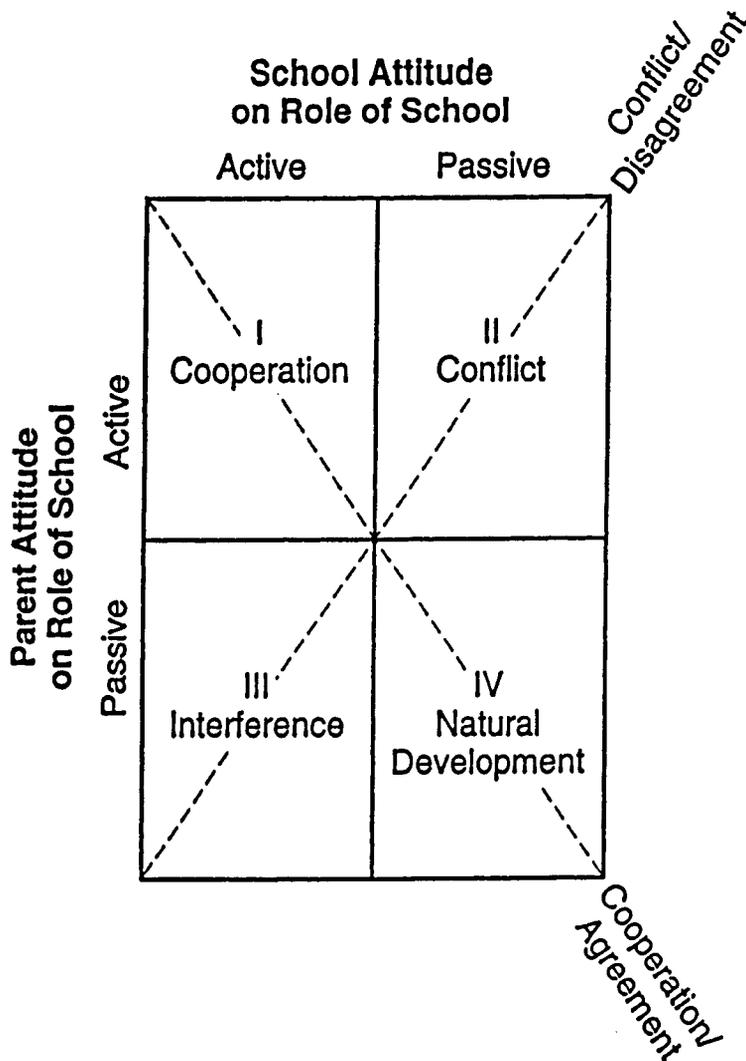

Figure 1. A Conceptual Model of Four Types of Parent-School Interactions

Source: Reprinted by permission of the authors and publisher from N. Colangelo and D. F. Dettman (1982), "A Conceptual Model of Four Types of Parent-School Interactions," *Journal for the Education of the Gifted*, Vol. 5, pp. 120-126

We have found that parents usually take one of three approaches in this Type II conflict. One is that they continually fight the school. They may either demand meetings for further discussion or join forces with other parents to assert their position. In the second approach, parents take it upon themselves to provide the special programs needed by a child. These may include summer enrichment activities, museum trips, college courses, tutors, mentors, and sometimes even private schools. Obviously, this approach is limited by educational background and financial resources of the parents. The third approach occurs when parents feel hopeless. They believe that they can have no real effect and that all they can do is complain. For many parents, the end result is a withdrawal from direct communication with the school.

Type III (interference) interactions are also based on conflict, but with a reversal of the dynamics found in Type II. In Type III the school actively wants to provide for the gifted child but the parents do not agree. Parents are unsure if special programs for the gifted are helpful or necessary. They are concerned about what effect identification and labeling may have on their (gifted) child as well as on siblings who may not be identified. Parents may be concerned that special recognition will damage their child's peer relationships. Parents may also view identification and special programs as an interference in the normal educational development of their child. Meanwhile, the school believes that the child *does* need special consideration and is willing to provide it. Of course, the school is often frustrated by the parents' refusal to let their child participate in the school's special program.

Type IV (natural development) interactions are based on agreement by both parents and schools that the role of the school should be passive. This belief is founded on the premise that high ability will take care of itself ("cream rises to the top") and that very little can be done meaningfully to nourish extraordinary ability. Essentially, both parents and schools view the typical school curriculum and extra-curricular activities as providing enough challenge and variety to stimulate the development of high potential and ability. In Type IV interactions, parents and schools recognize and support the youngster's efforts but believe that the natural development of talent will take its course, if the talent is truly there.

#### *Implications of Parent-School Interactions*

The model in Fig. 1 accounts for both *process* and *outcome*. The process relates to the nature of the interactions—that is, cooperative or conflictual. The outcome relates to the four possible types of content and results of the interactions when parents and school communicate about the school's role in gifted education.

The model can be used as a diagnostic instrument for helping both parents and school staff understand their interactions. The model also provides counselors with a framework for understanding their interactions with parents and other school staff—thus gaining insight into *how* they will deal with issues regarding programming for gifted children. Counselors can use this model not only to determine the type of interaction that *exists* between the school and parents, but also to assess what type of interaction would be *preferred*.

#### **Underachievement**

Perhaps the most intense counseling focus has been on the underachieving gifted student. In the Family Counseling program at The Connie Belin & Jacqueline N. Blank International Center for Gifted Education and Talent Development, underachievement has been the number one presenting problem. The issue of underachievement is confusing because of disagreement about its definition and the inconsistency of results from interventions (Whitmore, 1980; Dowdall & Colangelo, 1982; Delisle, 1992; Peterson & Colangelo, 1996; Reis, 1998).

Underachievement is seen as a discrepancy between assessed potential and actual performance. The discrepancy may be between two standardized measures (e.g. IQ and achievement tests), or between a standardized measure and classroom performance (e.g. teacher expectation and performance on daily assignments). The label 'gifted underachiever' implies a learner with a high level of potential (Reis, 1998). There are some measures, usually a standardized test, where a student meets the criteria for giftedness, while actual school performance is well below the assessed potential.

There have been a number of attempts to categorize underachievers. Reis (1998) distinguished between chronic and temporary (situational) underachievement. Temporary underachievement is often in response to a situational stress or event (e.g. divorce, loss of a friend, problems with a teacher). A chronic underachiever is one who has a 'history' and pattern of underachievement which appear to cut across a particular incident or circumstance.

Whitmore (1980) proposed three types of underachievers: aggressive, withdrawn, and combination. Aggressive students demonstrate disruptive and rebellious behaviors; withdrawn underachievers are bored and uninvolved. The third type is a combination of aggressive and withdrawn and the underachiever vacillates between aggressive and withdrawn behaviors.

Delisle (1992) proposes the categories of underachiever and a non-producer. Delisle makes an extensive comparison between the two categories. For counselors, however, the most important distinction revolves around the counseling needs of the student. The non-producer has minimal counseling needs and is

the type of student whose non-productive behaviors can be reversed with minimal intervention. Underachieving behaviors require a strong counseling program that may include family counseling. Most significantly, underachievement, according to Delisle is a problem that demands a long-term solution.

To a school counselor, technical definitions and categories are not as critical as the interpersonal dynamics involved in underachievement. Rather than looking at it as a psychometric event, we see it as a relationship between the gifted student and teachers, parent(s), and sometimes peers. For some gifted students underachievement is a way to express either a need for attention or a need for control over a situation. Underachievement brings considerable attention from both teachers and parents, in extreme cases almost doting behavior. Adults are so concerned that the gifted youngster will not make good use of his or her gifts that they give a great deal of energy and time to the student.

Counselors can often break the attention-getting cycle by having parents and teachers avoid responding too strongly to the underachieving behavior or even ignoring it. They can give attention when the child achieves well and minimize attention when the child is not achieving. The equation is simple. If the child wants attention, he or she will soon learn that the attention is forthcoming only when certain achieving behaviors (and attitudes) are present. The child will want to do more of these kinds of behaviors because the reward is the attention.

A gifted youngster who uses underachievement as a means to gain control of a situation offers a more difficult challenge. For such youngsters, poor achievement is a way to show teachers and parents that they (the students) can do what they want. A typical reaction by teachers and parents to this kind of defiance is to attempt to force the student to do the task and do it at levels comparable to expectation. This situation can lead to a vicious and non-useful cycle of 'power struggle'. The counselor can work with teachers and parents to help them quit the fight. It is likely the student will diminish the fight relationship if there is no one to fight with.

Minimizing the power struggle will allow more opportunity for the student to perform because he or she is more free to do so. Again, we propose that group counseling can help gifted students better understand their behaviors and motives and learn new patterns of interactions. It is in the rich atmosphere of a group of peers with a trained leader (school counselor) that a gifted youngster can explore motives and consequences of underachieving behavior.

Finally, it is important for the school counselor to use school records as a source of information in understanding gifted underachievers, especially at the secondary level. In a comprehensive study of 153 gifted underachievers, grades 7-12, Peterson and

Colangelo (1996) found data on attendance, tardiness, course selection and course grades, by gender and by age, that provided differential patterns that distinguished gifted students who achieved from those who underachieved. Peterson and Colangelo reported that patterns of underachievement established in junior high school, though not impossible to alter in high school, do tend to persist through high school. The school records are ubiquitous in schools and are a good resource for counselors.

While the issues surrounding underachievement are complex and research findings inconclusive and even contradictory, Reis (1998) provides a good summary of the current research on underachievement in the following eight points:

*First*, it appears that the beginnings of underachievement in many young people occur in elementary school.

*Second*, underachievement appears to be periodic and episodic, occurring some years and not others and in some classes, but not others.

*Third*, a direct relationship seems to exist between inappropriate or too-easy content in elementary school and underachievement in middle or high school.

*Fourth*, parental issues interact with the behaviors of some underachievers, yet no clear pattern exists about the types of parental behaviors that cause underachievement.

*Fifth*, peers can play a major role in keeping underachievement from occurring in their closest friends, making peer groups an important part of preventing and reversing underachievement.

*Sixth*, busier adolescents who are involved in clubs, extracurricular activities, sports and religious activities are less likely to underachieve in school.

*Seventh*, many similar behavioral characteristics are exhibited by bright students who achieve and underachieve in school.

*Eighth*, there are some students who may underachieve as a direct result of an inappropriate and unmotivating curriculum.

#### *Dual Exceptionalities*

Much of the literature on underachievement either states or implies psychological undercurrents (e.g. intrapersonal, interpersonal, and family dynamics). While the psychological issues have clearly been shown to play a role in underachievement, it is critical to note that not all underachievement behaviors have a psychological root. The presence of learning and developmental disabilities have been shown to be associated with both giftedness and underachievement.

The later 1980s as well as the 1990s brought a new awareness to the field of gifted education: gifted students who also have disabilities, especially learning, developmental, and social-emotional disabilities. Dual exceptionalities may include: autistic savant syndrome; developmental delays in speech, language and motor coordination; disruptive behavior (including conduct and oppositional-defiant disorders); anxieties, and eating disorders (Moon & Hall, 1998). Gifted children may also have specific learning disorders (LD), and attention deficit/hyperactivity disorder (AD/HD) (Moon & Hall, 1998).

The most common behavior disorder in gifted children is AD/HD (Moon & Hall, 1998) which can interfere with academic and social functioning. For gifted with LD or AD/HD, individualized testing will reflect patterns of inconsistency across talent areas (Moon & Hall, 1998). Multiple testing methods are typically needed to pinpoint areas of giftedness and disability (Moon & Dillon, 1995).

Dual-exceptionality students are at risk for underachievement because they will have barriers to achieving at their level of giftedness. Such students can become easily frustrated (and frustrating) since their inability to perform or 'behave' can bring about questions regarding their motivation and commitment. From observation, it seems dual exceptionalities are more common than most educators may think.

We strongly recommend a battery of individualized tests to determine exceptionalities in cases where gifted students are underachieving in academics and unable to function effectively in the classroom. Dual exceptionalities require a 'team' approach. School psychologists are in the best position to test and diagnose exceptionalities while the school counselor (and at times a school social worker) has the expertise for counseling the student and family regarding the dual exceptionalities.

### School Counseling Programs for Gifted Students

There are two ways to envision a school counseling program for gifted students: as *remedial* or as *developmental*. In the remedial approach, the emphasis is on problem solving and crisis intervention. In this approach, the counselor is primarily a 'therapy expert' who intervenes in problem situations either to help solve the problem or to minimize the difficulty. The counselor is involved in staffing, referrals, and one-on-one counseling. Where there is group counseling, the students are selected because they share a common problem (e.g. underachievement, behavior problems), and the purpose is to correct the problem.

In the developmental approach, the counselor does use his or her expertise to serve a therapeutic function and is available for problem solving, but therapy and problem solving are not their primary purpose. The real work of the developmentally oriented counselor is to establish an environment in school that is conducive to

the educational growth of gifted students. Such an approach is predicated on knowledge of both affective and cognitive needs of gifted youngsters. The focus of individual counseling is to get to know students and help them better understand their own strengths and weaknesses as decision makers and formulators of their lives.

Group counseling focuses on sharing perceptions and learning more effective interpersonal skills. Group members do not necessarily have a common problem to resolve. Work with families is based not on a problem with their child, but on the recognition that gifted children pose a unique challenge to parents. Family work is based more on discussion groups with parents in which the parents share information and connect with other families.

We strongly advocate a developmental approach to counseling with gifted students; giftedness is not a problem to be solved but a unique challenge to be nourished. In a therapy model, evidence of a problem would be necessary to justify having a counselor with expertise in working with the gifted. However, a developmental approach does not depend on research evidence that gifted youngsters are 'at risk'.

A developmental counseling program requires the following components:

- (1) An articulated and coherent rationale.
- (2) A program of activities based on the affective and cognitive needs of youngsters.
- (3) Trained counselors who are well grounded not only in counseling but also in giftedness.
- (4) A minimum of attention to rehabilitative (therapy) services, but a strong component of individual, family, and teacher consultations.
- (5) Input and participation from teachers, administrators, parents, and the youngsters who are served.
- (6) A component for the continued professional development of the counselor so that he or she may keep pace with the latest research and practices on the counseling needs of gifted youngsters.

### Summary

Although concern for the counseling needs of gifted students can be traced back to Leta Stetter Hollingworth's work of nearly seventy years ago, the emergence of counseling as a major force in the education of the gifted and talented is a phenomenon of the last two decades. Individual, group, and family counseling are predicated on the assumption and evidence that youngsters with exceptional ability and talents also have unique social and emotional needs.

These unique needs exist and interact in the successful or unsuccessful development of talent. Counseling is a necessary component in the successful development of talent. For counselors to be successful, they need knowledge and expertise both in counseling

and in giftedness. A developmental counseling program in a school will foster both the cognitive and the affective growth of gifted youngsters.

# Underachievement in Gifted Children and Adolescents: Theory and Practice

Willy A. M. Peters<sup>1</sup>, Helga Grager-Loidl<sup>2</sup> and Patricia Supplee<sup>3</sup>

## Introduction

One of the risks that gifted students face is underachievement. According to Richert (1991) there is reason to assume that "at least 50% of students identified through IQ have been designated as academic underachievers" (p. 140). This figure does not include students who were identified as gifted on a basis other than an IQ-test, so the problem seems widespread among the population of gifted students.

The most basic definition of underachievement is a discrepancy between actual achievement and intelligence. In the famous study by Terman, it appeared that gifted individuals did not achieve as well as could be expected on the basis of their intelligence scores (Terman & Oden, 1947). Durr (1964) defined underachievement as a difference between IQ-score and actual school achievement, measured in grades or achievement tests. However, the measurement of ability or the potential to achieve is problematic according to Raph, Goldberg & Passow (1966). For that reason, many attempts have been made to operationalize underachievement in ways that minimize the three problematic measurement issues: ability, performance and the discrepancy between them. Despite the difficulty, according to Tannenbaum (1991) one should try to define underachievement because there are few teachers who would deny the existence of students who exhibit this phenomenon. He cited Thorndike (1963, in Tannenbaum, 1991) who warned researchers to be careful and keep psychometric theory in mind while operationalizing underachievement.

There have been many descriptions of ability domains. Tannenbaum (1993) gives several examples, with the Marland report being of historical interest for its influence on provisions for gifted students in the USA. Supplee (1990) cites the Education Consolida-

tion and Improvement Act (PL 97-35) which defines gifted children as those "who give evidence of high performance capability in areas such as intellectual, creative, artistic, leadership capacity, or specific academic fields, and who require services or activities not ordinarily provided by the school in order to fully develop such capabilities" (Sec. 582). This text implicitly suggests that some children will not develop their potential if special support is not given, thus becoming underachievers. Gardner (1983) is currently influential in enumerating domains of ability.

The achievement-oriented and socio-cultural/psychosocial oriented models of giftedness (Mönks & Mason, 1993) include other variables in addition to general intelligence that must be present to allow gifted potential to develop and lead to high level achievement (e.g. Renzulli, 1978; Tannenbaum, 1983; Heller 1992). By default, this model of giftedness implicitly recognizes the fact that ability does not automatically imply achievement of the same level. Intervening factors can lead to lower achievement.

The lack of a widely accepted model of giftedness or consensus about the nature of intelligence implies that every theory about underachievement must be evaluated within the framework of a specifically defined theory of intelligence. This chapter deals with underachievers in the realm of logical-mathematical and verbal intelligence as Gardner (1983) would describe it.

Among the factors that contribute to underachievement, motivation can be regarded as one of the most important. Loss of motivation accompanies a decrease in achievement (Terman & Oden, 1947; Rimm, 1986; Butler-Por, 1993). Kaufmann (1999) has a different approach, seeing underachievement as a result of discouragement. Kaufmann's position might lead to a different view on interventions, but also recognizes the role of the environment in bringing about underachievement.

In this chapter, first the identification of underachievement is discussed. Assessing underachievement is viewed in two strands. The first type of assessment is through the practice of education and counseling. It is a task for teachers and counselors to recognize

<sup>1</sup> Center for the Study of Giftedness, University of Nijmegen, Netherlands. E-mail: wpeters@psych.kun.nl

<sup>3</sup> Center for the Study of Giftedness, University of Nijmegen, Netherlands.

underachievement when it happens. Researchers carry out the second strand. They assess underachievement in order to be able to study the phenomenon and develop strategies to overcome it. Groups at risk are discussed before factors that induce underachievement are presented. These factors include family and school factors, the influence of peers, and personality characteristics of the individual. To conclude, programs and intervention strategies are presented.

### Identification of Underachievers

#### *In Research*

Due to the lack of consensus regarding the nature of the discrepancy, it appears nearly impossible to create standards. The empirical literature reveals a number of different approaches to the problem of distinguishing between achievers and underachievers, each using criteria that are to some extent arbitrary (Ziegler, Dresel & Schober, 2000). An early attempt to set a standard was carried out by Shaw (1964). It was proposed that in those cases where the IQ-score belonged to the top quartile while achievement scores were below average, one might truly speak of underachievement. However, as Span (1988) stated, achievement scores can be on or above an average level and still the difference between achievement and ability can be so great that it is appropriate to speak about underachievement. Hanses & Rost (1998) believed that a relative criterion alone would not be sufficient. A student with an IQ score of 160, for example, and school results at the 95th percentile could be underachieving. Of course, one could argue that the reliability of the measurement of IQ scores at that level is so very low that the argument does not hold in practice.

Ziegler, Dresel & Schober (2000) proposed an assessment procedure in four phases. It is the first phase that is of interest here. The discrepancy between actual and expected achievement has to be determined. According to these authors, there are so many ways to measure actual achievement in the school as well as in other domains, that this part would not be problematic. The measurement of expected achievement is another matter. The diagnosis of what can be expected from a student has to be determined from several variables that predict achievement. The decision of which variables to include depends on the framework of the specifically defined theory of intelligence in which the concept of underachievement is couched, the theoretical perspective. When sound criteria in the form of standardized tests are not available to measure ability, so-called Delphi-criteria may be used. These are estimations of experts in the field, e.g. a sports trainer, who can estimate the possible level that a pupil might attain. However, this type of assessment yields great problems in the case of academic underachievers. Prejudice may arise in the minds of raters due to long

lasting underachievement, and an intelligence test seems to be essential in order to counteract it.

It must be clear that intelligence is not the only variable that would predict achievement. Ziegler et al. (2000) pointed to the criterion proposed by Hanses & Rost (1998) who formulated the significant discrepancy as the difference between ability at the top 5% and achievement below 50%. A similar criterion was formulated by Colangelo, Kerr, Christensen & Maxey (1993). Unfortunately, using these criteria, students who attain school results on or a little above average are not considered to be underachievers. As Ziegler et al. (2000) noticed, this criterion as well as the use of one standard deviation are both arbitrary; they suggest that everyone should establish criterion of their own.

Thorndike (1963, in Tannenbaum, 1991) warned of methodological problems in the determination of underachievers. He suggested the following questions as guidelines:

- (1) Have I an appropriate procedure for determining expected achievement?
  - (a) Have I taken account of statistical regression?
  - (b) Have I used the best team of predictors to establish expected achievement? Have I included aptitude? Initial achievement? Other appropriate factors?
- (2) Do I have a criterion measure of achievement that has the same meaning for all cases?
  - (a) Have I procedures to check for criterion heterogeneity?
  - (b) Have I a plan to deal with heterogeneity if it is found?
- (3) Am I aware of the effect of errors of measurement on my study?
  - (a) In reducing sensitivity?
  - (b) In producing bias? (p. 65).

Thorndike's questions remain a solid basis on which to develop criteria that have greater authority, if only because of the psychometric standards that are set. Similar to these guidelines, Van Boxtel, Mönks, Roelofs & Sanders (1986) developed a methodologically sound procedure to identify underachievers. This procedure is based on psychometric theory and takes into account the psychometric properties of the measurement procedures that are used. Basically, their approach focuses on the discrepancy between obtained test scores for intelligence and school results that are reflected in grades. The first step is to transform both test results and school grades to standardized scores ( $\bar{X}=100$ ,  $s=15$ ). In assessing the intelligence score, one has to deal with the regression effect. This means that extreme scores usually reflect a true score that lies closer to the mean. So, the intelligence score has to be corrected for this regression to the mean. The school grades consist of repeated measures, since the grades should be obtained not from one test only, but preferably by taking the average results over a longer

period of time. The next step would be to determine the regression equation for the 'prediction' of school results on the basis of the intelligence score. This regression equation is needed to determine the reliability of the difference between the 'predicted' and the actual school results. With the reliability coefficient, it can be determined whether a difference between actual and 'predicted' school results is significant (p. 171–176). This procedure was used in later empirical research (Van Boxtel & Mönks, 1992, p. 175–176).

Another procedure was proposed by Lupart & Pyryt (1996). In their approach, the first step was to determine the correlation between the IQ and school achievement, as expressed in the last report form from the school. Next, the expected achievement was determined in different school subjects on the basis of the IQ-score. The standard error of estimate for predicting grades in each school subject was determined and the actual achievement score was subtracted from the predicted achievement scores. Finally, individuals with a discrepancy beyond one standard error of estimate for the grades were nominated as underachievers. The rationale for this approach can be found in Thorndike (1963, in Tannenbaum, 1991).

### *In Practice*

As in research, the assessment of underachievement in practical settings such as education and counseling does not have fixed standards. The procedures described above are hard to apply in practical settings such as schools.

A completely different approach was used by Baum, Renzulli & Hébert (1995). In their investigation, underachievers were assessed by asking the teachers to determine who was underachieving. These assessments were made by the classroom teachers and the teachers of special programs for gifted students.

Hany (1991) compared intricate scientific procedures with teachers' judgement. Although the standardized procedures yielded results, Hany suggested that teachers' judgements can be improved by informing them about aspects of giftedness and underachievement. The level of reliability of their judgement could then come close to the quality of standardized procedures.

Butler-Por (1993) also emphasized the importance of training teachers. She proposed a procedure for use in schools that is applicable when teachers possess a minimal understanding about underachievement. This procedure has five steps:

- (1) Identification of discrepancies between cognitive abilities expressed in formulating questions and hypotheses and normal school performance in the accomplishment of assignments, homework, and tests.
- (2) Identification of great differences between general and expert knowledge derived from extensive

reading at home, yet failure to complete reading assignments at school.

- (3) Comparison between a student's wide interests outside the school with minimal effort invested in school projects.
- (4) Combined student and teacher evaluation of academic strengths and weaknesses, academic personal choices and effort invested in the different subjects.
- (5) Consulting parents, previous teachers and professional personnel at school on student's learning habits and social behavior. A consistent drop in scholastic performance of approximately two years indicates that the student is underachieving. (p. 651).

In comparison to the meticulous psychometric way of dealing with the identification problem in research, this practical approach gives criteria for teachers to use, teachers whose task is to work with children and improve their situation, not merely study them.

Other approaches to identifying underachievers in school settings have been reported in the literature. Peterson & Colangelo (1996) suggested that data from school files could be used to determine which students were underachieving. Variables that could be used were: attendance, tardiness, and course selection. Redding (1989) argued that (verbally gifted) underachievers lack task commitment and appreciation for detail. In the assessment procedure, the educator would be wise to focus on the possibility of partially high test scores. This means that full-scale scores such as IQ are not the only, maybe even not the most important, variable to consider. Attention should be paid to the pattern of subtests across domains to identify the areas in which strengths of the individual are to be found.

### *Underachievement in Testing Situations*

A phenomenon that has attracted little explicit attention so far, is underachievement in testing situations. Of course, test anxiety is a known phenomenon, but it seems that investigators seldom take the implications into account. In addition to test anxiety, other factors may play a negative role during testing: high expectations of others, specific learning problems that are related to the testing procedure (e.g. multiple choice exams) and fear of failure due to unsuccessful experiences with tests (Kerr, 1991). Research of error patterns in test responses, shows that 'illogical' mistakes may point at certain characteristics of students that: (a) evoke underachievement behavior and (b) result in lower test scores than would have been appropriate (Peters & Van Boxtel, 1999). Investigators should keep in mind what Kaufman (1994) wrote about this:

When an examiner is able to relate observations of the child's behaviors in the testing situation to the profile of obtained scores (e.g. by noting that the

child's anxiety disrupted test performance on all timed tasks), two things occur: (a) The examiner learns important information about the child that can be translated to practical educational suggestions, thereby enhancing the value of the intelligence test; and (b) the actual IQs earned by the child may become gross underestimates of his or her real intellectual abilities. In general, the actual IQs are valuable because they provide evidence of a child's mental functioning under a known set of conditions and permit comparison with youngsters of a comparable age. The value of the scores increases when the examiner functions as a true experimenter and tries to determine why the child earned the particular profile revealed on the record form; the IQs become harmful when they are unquestioningly interpreted as valid indicators of intellectual functioning and are misconstrued as evidence of the child's maximum or even typical performance. (p. 9).

### Groups at Risk

There is ample evidence that certain groups of individuals are more prone to underachievement than others. When dealing with these groups, educators and counselors should be more open for signals that could indicate underachievement. A number of groups can be found in the literature to be at risk for underachievement. Feger & Prado (1998) and Butler-Por (1993) described a number of groups that can be distinguished:

- (1) Geographic—ecological factors: Living in areas that offer few challenges due to geographic or ecological reasons.
- (2) Ethnic factors: Being member of a nation that is discriminated against on the basis of ideological or religious reasons.
- (3) Economic factors: Living in poverty or lacking the means to develop abilities.
- (4) Gender factors: In many cases girls are in disadvantaged positions.
- (5) Educational deprivation: Often due to the factors mentioned above, but also due to other reasons, such as the school providing too few opportunities.
- (6) (Sub)-Cultural factors: Growing up in a subculture that is deviant from the dominating culture.
- (7) Physical or psychological problems: Physical or psychological illness will have a negative effect on achievement.
- (8) Family factors: Disturbed relations between parents and their children, e.g. when a child is unwanted or rejected, or when family stressors such as divorce or separation are present.
- (9) Active disrespect for societal norms: Taking part in delinquent activities.

- (10) Being highly creative: Children in this category may be pressed to become more conforming.

### Gifted Girls

Gender is a returning theme in the search for factors that contribute to underachievement. Just as in giftedness in general, researchers have tried to learn from successful women how their development was shaped (Arnold, Noble & Subotnik, 1996). An important issue to be dealt with is whether girls themselves take an underachieving position due to certain personality or other factors, or whether the environment in which they grow up puts them in a vulnerable position.

There is evidence that personality characteristics play a role in turning girls into underachievers. Non-assertiveness, fear of success, perceived low social competence, and perceived negative self-concept could be identified as such (Hollinger & Fleming, 1984). Highly able girls are more at risk to develop psychosomatic illnesses such as anorexia nervosa, in comparison to girls with an average ability (Detzner & Schmidt, 1985). Girls show less ambition than do boys (Freeman, 1993) and hide their abilities (Kerr, 1991). In programs for science and maths, girls tend to be underrepresented (Wieczerkowski & Prado, 1992; Feldhusen & Jarwan, 1993), which might be due to a different value-system in girls which does not include pursuing academic achievement. The differences between girls and boys become more visible at the onset of adolescence, when the priority changes to social approval instead of academic achievement (McCormick & Wolf, 1993). Case studies have shown that gifted girls need an accepting and stimulating environment which supports their academic activities (Reis & Diaz, 1999).

Of course, these characteristics of girls do not exist in a social vacuum. The social environment influences the genesis of these characteristics to a large extent. One could argue that most, if not all, characteristics mentioned above are induced through environmental influence. Probably because of this, some authors have shifted their attention more explicitly to environmental influence on the (under)achievement of girls. Often the academic ability of girls remains unnoticed (Heinbockel, 1996). Parents, together with their daughters, tend to choose a lower form of higher education for girls than they do for boys (Freeman, 1993). Also participation in gifted programs is rejected more frequently for girls than for boys (Butler-Por, 1995). Academic success can lead to negative responses because it is not part of the set of characteristics expected of girls (Gallagher & Gallagher, 1994). It is the environment that urges girls to give up aspirations in the fields of science and maths (McCormick & Wolf, 1993). The phenomenon, which encourages girls not to accelerate, is called 'fear of success': the negative effects outweigh the positive. A stimulating environment for girls

should offer them support to achieve and follow their own aspirations (Reis & Diaz, 1999).

### *Cultural Minorities*

Another group that is prone to underachievement consists of children from cultural minorities. It is widely reported that these groups are under-represented in programs for gifted students (Butler-Por, 1993; Ford & Webb, 1994; Butler-Por, 1995; Ford & Thomas, 1997). One of the factors that may cause children from cultural minorities to appear to underachieve would be the fact that curriculum activities do not match their cultural competencies (Hébert, 1998). (Sub)cultural differences in values and beliefs influence achievement. If a (sub)culture does not acknowledge success at school as important, children from this background have to deal with different standards and expectations in the school and non-school worlds in which they live (Kitano, 1991; Ford, 1992, Ford & Harris, 1992). Another important factor that contributes to underachievement is the lack of early appropriate academic experiences (Diaz, 1998), yet different cultures hold widely different beliefs about the importance of formal preschool. These differences may affect the daily activities of children such as reading books and time usage.

Many children live the first years of their life in their own (sub)culture then enter school, an entirely different culture. An example of this is Turkish children in Berlin, Germany (Feger & Prado, 1998). The differences between cultures will yield differences in personality structures. The value conflict may affect their sense of self-worth (Ford & Thomas, 1997).

### *Children in Critical Situations*

Environmental disadvantages that may lead to underachievement are connected with critical events that might take place within the family or within the direct living environment of the child. Such critical events might be: marriage problems between the parents or divorce, unstructured family relations, early separation of the child from the parents, especially the mother, birth of siblings, illness and death of family members, having handicapped siblings, and violence and/or sexual harassment within the family. No-one will wonder that these experiences will have a negative effect on the achievement potential of a child (Friedrich, 1998). Typical behaviors that follow such trauma could be a drop in achievement, concentration problems, memory gaps, and perceptual difficulties (p. 91). Other events may also have an effect that could be underestimated. Webb, Meckstroth, & Tolan (1982) noticed that gifted children are more sensitive than their peers. Because of this, they may experience more of an impact from stressful events. Typically results include avoiding contact and even more, being unable to concentrate simply because one's mind is some-

where else. Children might even unconsciously ask for help by dropping achievement. "The gifted student, aware of his or her reputation as an excellent scholar, may be counting on the counselor to notice the change in his or her grades, to comment upon them, and to offer help and support" (Kerr, 1991; p.62). Butler-Por (1993; 1995) asked for attention towards children in a divorce situation.

### **Etiology of Underachievement**

Research on etiological factors of underachievement has made clear that it is unlikely that only one factor will be the cause. Usually, several factors come together to contribute to sudden drops in achievement or in a slow decline in achievement scores. In determining what factors would be most important, Baker, Bridger & Evans (1998) distinguished three etiological models: individual, family and school. In their report, all three models turned out to predict significantly whether or not an individual student would develop into an underachiever. Yet, the combined model gave the best goodness-of-fit. This means that underachievement is best predicted when all three models are taken into account.

Mönks' triarchic model of giftedness (Mönks & Mason, 1993) included peers as a separate area of influence. Since this achievement-oriented model was also concerned with how ability can be realized, it seems logical to combine the factors from these two models. Therefore, the factors that evoke underachievement behavior can be ordered as follows: family, school, personality, peers.

### *Family Factors*

The relationship between children and their parents is of the utmost importance. Butler-Por (1993) described the situation of these children: "Rejected children who are not receiving appropriate nurturing, reinforcement, and support are unable to understand what is happening to them and what is expected of them. They are unable to acquire coping skills, to gain confidence and build a realistic self-concept" (p. 653). Children from divorced parents are at risk as well, as described before. Nevertheless, Lee-Corbin & Evans (1996) described that parents may diminish the negative influence of the divorce situation by investing time and effort in their children and by avoiding involvement of the children in the conflict between the partners. Another factor of influence is the expectations that parents hold; high expectations seem to support achievement. Richert (1991) also stressed parental influence and described that the difficult task for parents would be to model the behavior that they wish to stimulate in the child. It may be hard for parents to tune their expectations to the level that is appropriate for the child. In many cases, parents expect too little from the child (Stapf, 1998), e.g. when parents try to hold back the young child from

reading because he may get bored later in school. The result may be that pleasure in reading, arithmetic, thinking will be gone.

But expectations can also be too high. In many cases the child is being pushed "to be continually successful in examinations, possibly at the expense of more challenging intellectual, artistic and emotionally satisfying activities" (Freeman, 1998; p. 7). In some cases, these parents see a second chance for themselves in their children. They wish to compensate for their own unfulfilled wishes. The children's achievements and successes become more important than the abilities and needs of the children themselves (Webb, Meckstroth & Tolan, 1982; Mönks & Ypenburg, 1998). Children will hesitate to show school results to their parents if they do not meet the high standards of the parents (Perleth & Sierwald, 1992; Zielinski, 1998). This will occur even more so if the affective relationship between parents and child depends on the achievement of the child. When parents overvalue achievement, gifted children who are already at risk of becoming perfectionists will get an even greater push in that direction (Freeman, 1997; Mönks & Ypenburg, 1998).

The best parents can do is demonstrate the behavior that they want the child to display. The consistent and thorough style of working that is necessary for success in the academic realm, especially, can best be learned from models within the family (Winner, 1996). When children grow up in an environment where it is normal to read books, go to museums or experience other ways of exploring the world, they regard it as normal to adopt these behavioral patterns. Not only the activity per se, but also the pleasure in exploring can be handed down to the children by their parents. One has to start showing the joy in exploration while the children are as young as possible (Freeman, 1992). The parents not only function as models, but also as partners that can help to get access to resources.

As a background variable, the achievement goals that parents hold for their children may influence achievement behavior. Achieving children tend to have parents whose achievement goals are more in learning rather than in performing (Ablard & Parker, 1997). When parents and child join in this type of behavior on a basis of mutual interest, an important basis for understanding adequate achievement will be formed. This may be easier said than done, since the exploration need that is displayed by some children will get on the parents' nerves. Children need supportive parents and teachers, but must also have qualities of their own, such as concentration and presentation skills, task commitment, a positive self-concept and social abilities. Achievement is negatively influenced when various combinations of these factors are missing (Lee-Corbin & Denicolo, 1998).

The parenting style that is used should be neither authoritarian nor too permissive (Zielinski, 1998). A

good optimum between these two extremes offers the best possibilities for children to develop explorative behavior in a safe environment. When parents hold the right amount of control over their children, the urge to discover new things will be maintained in the child (Butler-Por, 1993). However, with too few guidelines, there is a risk that children will grow up with too little sense of responsibility, or 'caring' (Webb, 1995).

#### *School Factors*

School is the place where most underachievement behavior becomes visible. But as research indicates, it cannot be the only place where underachievement is overcome, since the etiological factors can also be found outside of the classroom (Baker, Bridger & Evans, 1998). In many cases, a latent underachievement pattern may become visible when the child enters school; an example could be creative thinking. When a child notices that parents have some problems with 'creative initiatives' that are taken by the child, the child may conclude that it is better to try as much as possible to adapt to the standards that are set. This will lead to a loss of creative potential. Problems may also arise for the child in trying to adjust: "The inability of highly creative children to satisfy the demands of parents and school may lead them to choose to psychologically 'opt-out' and adopt underachievement behaviors" (Butler-Por, 1995; p. 253).

According to Heller (1992) the organization of teaching and the personality of the teacher were the two main factors that influenced the achievement of children in the classroom. Butler-Por (1993) added to this the attitude that the pupil has towards school; this may be displayed in less care for their schoolwork, e.g. with a sloppy handwriting (Lee-Corbin & Evans, 1996). Underachieving students tend to have peers with more negative school-attitudes (Ziv, 1977). This effect is strong, because peers among each other influence their mutual attitudes; when the students are not actively involved in their work, it will be impossible to recognize abilities (Drewelow, 1992). Inactivity and boredom not only hinders the teacher in observing capacities in students, it also induces underachievement (Freeman, 1993). In the classroom, the student needs to find impulses that strengthen his motivation; in order to respond to student needs, the learning situation should, as much as possible, allow students to delve into areas of their own interest. In so doing, motivation increases and the students actually work and develop their learning skills. This development of learning skills, especially self-regulating skills, is an important factor in preventing or overcoming underachievement (Redding, 1990; Baum, Renzulli & Hébert, 1995; Lee-Corbin & Evans, 1996). Effective goal setting for academic achievement and appropriate instruction and curriculum are interventions that can reverse underachievement (Emerick, 1992).

On the other hand, teachers' lack of awareness of aspects of giftedness and underachievement may evoke underachievement in students (Gross, 1999). Teachers' low expectations for children can encourage underachievement in three ways: (1) the mechanism of self-fulfilling prophecy will make students behave according to the expectations of the teacher; (2) perceptual bias will give the teacher wrong ideas about the abilities of students; (3) incompatibility of teaching and learning styles of teacher and student may also mislead the teacher about students' capabilities.

Grading practices, e.g. when teachers give lower grades as a punishment for rule-breaking classroom behavior, also encourage underachievement because students may feel rejected by the teacher (Kolb & Jussim, 1994). When teachers' conceptions are changed, it alters the negative impact on the students. There is evidence that preconceptions can be altered which in turn will positively affect the achievement (Ribich, Barone & Agostino, 1998).

Teacher characteristics may reverse underachievement. One teacher characteristic that has a very positive influence on underachieving students is what Renzulli (1992) calls "romance with the profession." Being actively and emotionally involved with their own discipline, teachers function as powerful role models. Feldhusen (1986) listed characteristics that are useful if not necessary for teachers of gifted students: (1) good organization of their teaching; (2) self confidence; (3) flexibility; (4) capable of enthusing students; (5) positive attitude towards excellence; and (6) extensive general knowledge. Next to these more or less formal characteristics, good teachers of the gifted need the knowledge to be able to generate questions. They need to feel free to raise questions, and they need the courage to question the answers (Webb, 1995). These characteristics make teachers supportive or cooperative (Lee-Corbin & Denicolo, 1998).

Of course, it cannot be expected that teachers will understand (gifted) underachievers without any help; a support system, may be in the form of in-service training, is needed to teach them how to deal with underachievers (Freeman, 1997). It is known that teachers have a limited capability to recognize gifted potential without any training, yet this ability can be improved (Hany, 1991; 1997; Rost & Hanses, 1997). Teachers also need to know what characteristics describe underachievers. Because of the hidden character of underachievement, it may be hard for teachers to recognize underachievement when it is taking place. Information about students that comes from other sources may help them; an example would be the school files that are gathered during the years that students are at school (Peterson & Colangelo, 1996). Information that may be found could include school attendance and tardiness, course selection, and onset and duration of underachievement.

Another aspect of teacher behavior is praising. Kaufmann (1999) considered underachievement to be a matter of discouragement, claiming that praise has especially negative results on discouraged students. Praise may strengthen the notion that one is valued only for the achievement that has been reached. It will "foster the dependency, conformity and external motivation at the heart of the underachievement phenomenon" (p. 9). On the other hand praise can be regarded as advantageous when it is used properly. Winner (1996) underlines that it is necessary to praise when work of substance has been done; the repeated acknowledgment of good work and effort should help to overcome underachievement behavior (Freeman, 1998).

#### *Personality Factors*

When gifted children experience extreme boredom, when they cannot develop and train their thinking skills, and when they do not develop satisfying social relations, their self-concept will deteriorate (Gallagher, 1991; Heller, 1991; Van Boxtel & Mönks, 1992; Gallagher & Gallagher, 1994; Freeman, 1998; Hanses & Rost, 1998; Lee-Corbin & Denicolo, 1998). The nature of the relationship between achievement and self-concept is under debate. Does achievement develop a positive self-concept? Or can one achieve better when the self-concept is positive? Both seem to be true, although there seems to be some evidence that achievement should have priority over the self-concept (Helmke & Van Aken, 1995). This would mean that leading students to greater achievement changes their self-concept more than vice versa.

Closely related to self-concept is the notion of control. Individuals who possess a positive self-concept tend to believe that they, themselves, are in control of what happens to them (Laffoon, Jenkins-Friedman & Tollefson, 1989). Individuals with a more positive self-concept are more motivated and believe that they are responsible for their success, e.g. in maths (Vlahovic-Stetic, Vidovic & Arambasic, 1999). However, this relationship between locus of control and achievement is not clear. It seems that gifted children in general tend to have a more internal locus of control. There seems to be no clear relationship between underachievement and locus of control (McClelland, Yewchuk & Mulcahy, 1991; Peters & Van Boxtel, 1999). Yet, gifted students who undergo so-called attributional retraining do gain in achievement (Heller, 1999). Could it be that an internal locus of control can increase achievement, but does not have the impact to overcome underachievement?

As can be expected, motivation is a part of the underachievement problem. It is obvious that underachievers possess less motivation than their more successful peers (Baum, Renzulli & Hébert, 1995). The discouragement notion of Kaufmann (1999) implies this notion. Underachievers are reported to have lower

expectations of themselves, but also of what their teachers and peers could offer them (Colangelo, Kerr, Christensen & Maxey, 1993). A training program which includes volition as one of the targets proved to be successful in improving achievement in a non-academic setting (Teo & Quah, 1999).

Behavioral problems, overt or more concealed, were reported by many authors. Stapf (1998) describes signs of protest behavior in children in kindergarten, such as school refusal, disturbing play and classes, motoric restlessness, emotional disturbances, aggressive behavior, psychosomatic complaints and daydreaming. Behavioral problems will not always be displayed in school; on the contrary, parents have to deal with this problem most of the time at home (Freeman, 1994).

Among other variables, self-regulation and interaction with an appropriate peer-group may have a positive effect on underachievers (Baum, Renzulli & Hébert, 1995). One factor that influences behavior is the extent to which the individual is resilient (Bland, Sowa & Callahan, 1994); resilience enhances achievement (Ford, 1994).

One reason for problems in the realm of personality development or behavior, could be the lack of metacognitive and strategic skills; for example, underachievers are less capable of transferring skills from one situation to another (Muir-Broaddus, 1995). It seems, that underachievers can do well on holistic and divergent tasks, where no strategy has to be selected, in comparison to analytical and convergent tasks (Redding, 1990). The selection of strategies turns out to be a difficult issue for this group.

This lack of metacognitive ability in underachievers may have a cause that can be traced. It is commonly assumed that the process of learning must be learned, or trained, as well as the content of a curriculum. For this reason, the curriculum needs to offer instruction in how to learn as well as enough challenge on the level of difficulty of the content. Learning skills may not develop when the content of the curriculum does not match the level of cognitive functioning of the child (Perleth & Sierwald, 1992; Ulbricht, 1998).

### *Peer Influence*

The influence of peers on gifted children gets special attention, due to the fact that it might be difficult to actually find peers for this group. Problems arise when the gifted child tries to adapt to the behavior of the peer group when this behavior does not match the interests and needs of the gifted child himself. One reason for underachieving has been known for a long time already: simply lower the results so the peer group will not let one down (Colangelo & Dettmann, 1983; Perleth & Sierwald, 1992; Baum, Renzulli & Hébert, 1995). In some cases, not doing homework can become a condition of being accepted in the peer group. Winner (1996) also recognizes this phenomenon. Finding the balance between receiving social acceptance and

excelling in school is a major task for gifted students; this problem is especially present for girls. Luftig & Nichols (1991) discovered that there seemed to be a huge difference in the way peers perceive gifted girls and boys. Gifted boys were more popular in comparison with boys of normal ability. For girls, this phenomenon was just the opposite; this could be a good reason for some individuals to adopt underachieving behavior—to find oneself accepted again. Winner (1996) argued that the typical image of the gifted student was more in line with an acceptable image for boys. For girls a role conflict arose between the pursuit of excellence and the demonstration of feminine behavior to adapt to the standards of the peer group and gain social acceptance.

### **Furtherance and Interventions**

Underachievement is a persistent phenomenon that is not easily overcome. Several approaches have been developed and tested, all of them based in different theoretical and practical backgrounds. This makes comparison difficult; nevertheless one can learn from the work done by others.

As a start, it has to be said that intervention programs for underachievers still have to prove their effectiveness (Baum, Renzulli & Hébert, 1995). In the last decade, more and more programs have been presented. In these interventions there is a tendency to address not just one element, but to regard underachievement as a complex problem that needs to be worked on at several levels (Emerick, 1992).

As a prerequisite, parents need to give their consent for their child to participate in a program to overcome underachievement. It is better to include the parents in the program and show them ways in which they can help their child become a more effective learner (Colangelo & Dettmann, 1983; Rimm, 1991; Emerick, 1992). An important role for parents is to enhance the self-esteem of the child. Another is to become aware of stereotypical patterns of interaction that hamper achievement behavior.

An approach to reversing underachievement is to distract the attention of student, parents and educators from all that is not functioning well and to emphasize and elaborate on the strengths that are present in the individual (Willings, 1998). This enables the personal growth that is necessary to give the individual the strength to direct his own behavior again. Redding (1989) stressed the importance of paying attention to self-initiated successes gained by the children themselves. Furthermore, one could avoid continuously looking at school records to evaluate the development of the child. In the 'prism-metaphor', underachievement behavior is seen as an intertwined set of problematic factors that need to be understood, and separately addressed within the context of an intervention program (Baum, Renzulli & Hébert, 1995). This focus on broader programs is shared by other

authors (e.g. Redding, 1989; Emerick, 1992). Such an approach will be more effective than focusing on just one aspect of the behavior.

General psychological well-being, brought about through guided discussion in groups, can be targeted as a goal for underachievement programs (Peterson & Espeland, 1995). This program offers ready-made hand-outs and other materials to encourage discussion among peers. The goals that can be reached with this method are a better understanding of themselves with more self-awareness and self-esteem, a feeling of being more in control of their lives and having more confidence in the future.

A school program that involves parents and offers a broad variety of activities was developed by Supplee (1990). It focused on activities that can be programmed in school in different subject areas. Underlying the program for pupils in kindergarten through grade 8 was a focus on working and study skills. The training was made more attractive by transferring the assignments as much as possible to real-life situations and inviting the students to think about different solutions themselves. This program offered a holistic approach, yet was organized within the context of school; a similar type of program can be found in Kerr (1991). In some cases, the help of a counselor is included in the program (Fehrenbach, 1993).

The opposite can also be found; sometimes emotional problems reach a severity that requires psychological counseling. Focusing on these problems could turn out to be symptom-curing while allowing the underlying problem to continue. A behavioral approach can be better, giving insight through cognitive therapy (Golden, 1993) or family therapy using a narrative approach (Thomas, 1999). Another entry on a more psychological level would be attributional retraining (Heller, 1999). A program was developed to help students take responsibility for their own behavior based on attributional and achievement motivation theories. The program was designed for use in a school setting. One important aspect of underachievement behavior that can be changed in this way would be helplessness.

Aspects of the underachievement syndrome can be addressed with good results. A program that gave writing process instruction to gifted, learning-disabled and low achieving 2nd grade pupils proved to be successful in improving their attitudes towards writing, but also in the achievement that was realized in this area (Zaragoza & Vaughn, 1992).

Another example of focusing on an aspect of the underachievement syndrome is the training of meta-cognitive skills in early childhood (Manning, Glasner & Smith, 1996). This approach was successful in enabling young gifted pupils to develop their meta-cognitive skills and, in so doing, prevent underachievement; this type of training is also valuable for older pupils (Redding, 1989).

For secondary school pupils, a possible approach to reducing underachievement would be to individualize the goals that are set for educational provisions (Fehrenbach, 1993). This might enhance motivation and it supports the students in those areas where they need it. Another specific way of trying to overcome or prevent underachievement is grade skipping (Rimm & Lovance, 1992). Parents reported that the decision to skip a grade was successful, and in many cases, they even regretted not having taken this measure earlier. Early entrance however, does not seem fruitful in preventing underachievement (Sweeney, 1995). A comparison between gifted students who did and did not enter school before the regular date did not show meaningful differences in achievement between these two groups. The small difference that was found, though, was in favor of the early-entrance group.

If underachievement is mainly due to lack of motivation, a program from Singapore may be helpful (Teo & Quah, 1999). This 'Knowledge/Volition/Action'-program tries to foster the will to achieve in students. The result that achievement in the non-academic area seemed to benefit most from this program was striking.

The APOGEE-program brought students from different backgrounds together who were identified as gifted, but belonged to underprivileged groups such as handicapped or underachieving students (O'Tuel, 1994). In the program group work, projects and self-regulation were encouraged; results showed increases in critical thinking ability, self-esteem, and school attendance. Behavioral problems decreased and the students reported more positive attitudes towards themselves as learners.

A specific group that needs attention are gifted girls. For them, maths and sciences programs have been created, without boys present, to let girls develop skills in these areas where they tend to be underachieving (Lupart & Wilgosh, 1998). The content of the program is designed, among other things, to bridge the gap between school maths and science and post-secondary settings, such as college or business. Other programs focus on this group at another point in time. Early intervention and strengthening the ability of girls in the realm of maths and science is necessary to prevent the loss of ability and motivation in these subject areas (McCormick & Wolf, 1993).

Within a group of underachievers, one can distinguish subcategories that might need different types of programs (Richert, 1991; Schneider, 1998). Four categories of underachievers are the conformist, the rebel, the withdrawn, and the transceiver (Richert, 1991). Each of them needs support in six areas: (1) strengthening self-concept; (2) learning to cope with failure and success; (3) learning to unleash creative potential; (4) learning how to plan; (5) developing ways to evaluate results; and (6) providing role models.

The way this is done differs for every subcategory. A similar system is provided by Schneider (1998). Contrary to Richert (1991), the system of Schneider (1998) does not seem to be based on personality characteristics, but on behavior patterns.

### In Conclusion

Underachievement among the gifted appears to be a widespread phenomenon. Identification of these children has been attempted both psychometrically and informally, with many issues remaining in this area. Certain groups appear to be at greater risk, with risk factors cited including geographic, ethnic and gender, economic, educational deprivation, sub-cultural, physical, psychological and sociological factors. A number of interventions have been described that attempted to reverse underachievement with the most successful programs involving parents and addressing students' individual affective and cognitive needs in a manner appropriate for their age and the circumstances of their life.

# Attention-Deficit/Hyperactivity Disorder in Gifted Students

Felice A. Kaufmann<sup>1</sup> and F. Xavier Castellanos<sup>2</sup>

## Introduction

The issue of Attention-Deficit/Hyperactivity Disorder (ADHD) among gifted students poses challenging questions for researchers and practitioners. The most fundamental is the question of validity. Some authors (Lind, 1993; Cramond, 1995; Baum, Olenchak & Owen, 1998; Rimm, 1999) have questioned whether ADHD in high ability students is just a misinterpretation of gifted, creative or 'overexcitable' behaviors or a mismatch between school curriculum and child. Others (Kohn, 1989; Reid, Maag & Vasa, 1993; Armstrong, 1995; Freed & Parsons, 1997; Breggin, 1998; Diller, 1998) have argued that the concept is more reflective of society's ills than an actual medical condition.

In this chapter, we will present information about the co-occurrence of giftedness and ADHD with the assumption that the combination is real. We must acknowledge at the outset that much of the following material is based on our experiences as an educator and pediatrician/child psychiatrist, respectively, because to date there are no controlled and peer-reviewed studies on ADHD in gifted students. The bulk of the scientific information, therefore, will focus on what is known about ADHD in the general population but will be augmented by our speculations concerning the application of the material to gifted students.

## What is ADHD?

Attention-Deficit/Hyperactivity Disorder is the most common neuropsychiatric disorder of childhood (American Psychiatric Association, 1994). It is not a single disease, but a 'syndrome', i.e. a grouping of symptoms that typically occur together. The core symptoms of ADHD are impulsivity, inattention, and hyperactivity. These symptoms and related problems can be mild, moderate or severe, and may manifest in different combinations within familial, academic and social contexts.

Estimates of the prevalence of ADHD among school age children vary from 0% to 16% (Lahey et al., 1999), a range that reflects differences in research methodology as well as the heterogeneity and complexity of the condition. The median estimate across all definitions of ADHD and all types of studies is 2% in boys and girls combined (Lahey et al., 1999). The symptoms typically emerge in early childhood and frequently continue into adulthood, although the manifestations of the condition usually change over time (Biederman, 1998).

## What Causes ADHD?

A comprehensive review of the literature on the causes of ADHD is well beyond the scope of this chapter; a more extensive discussion of the empirical research on the topic is presented in another version of this chapter (Kaufmann, Kalbfleisch & Castellanos, 2000).

The question 'nature or nurture?' which underlies so much discussion about giftedness, also applies to ADHD. On the 'nature' side, family studies have confirmed that the chances that an individual will have ADHD is at least five times higher if he or she is closely related (sibling, parent, or child) to someone who also has ADHD (Faraone & Biederman, 1998). Moreover, recent research (Barkley, 1997) has revealed that a child of a parent with ADHD has up to a 50% chance of having the condition. Adoption studies also found greater similarities between children with ADHD and their biological parents than between those children and their adoptive parents (Castellanos & Rapoport, 1992). Furthermore, studies comparing the degree of similarity (concordance) between identical twins and fraternal twins have consistently converged on estimates of the heritability of ADHD ranging from 75% to 90% (Faraone & Biederman, 1998). Taken together, these investigations confirm that genetic factors strongly influence the development of ADHD.

Environment also contributes to the etiology of ADHD. Such factors as premature birth (Lou, 1996), head injury (Max et al., 1998), fetal alcohol syndrome (Streissguth et al., 1994), pre-natal cocaine (Levitt et

<sup>1</sup> 6520 Lone Oak Court, Bethesda, Maryland, USA.

<sup>2</sup> National Institute of Mental Health, Bethesda, Maryland, USA.

al., 1997), pre-natal smoking (Milberger et al., 1996), and high levels of psychosocial stress (Mayes et al., 1992; Richardson & Day, 1994) have all been linked to ADHD. Although diet has been implicated in popular literature, placebo-controlled studies of refined sugar have failed to reveal an association (Wolraich, Wilson & White, 1995). However, there continues to be interest in the possibility that dietary causes may be etiologically important in some fraction of cases (Breakey, 1997; Arnold, 1999; Baumgaertel, 1999; Jacobson & Schardt, 1999).

To summarize, there is no one cause of ADHD, any more than there is one 'cause' of giftedness. Both genetics and environment contribute to the condition as they interact with a child's growth and development.

### What is the Role of Development in ADHD?

Children with ADHD trail about 2–3 years behind age-peers in social development (Dykens et al., 1990) and in cognitive tests of prefrontal brain functions (Amin et al., 1993; Chelune et al., 1986). While children with ADHD and children without ADHD progress at the same rate, the developmental lag between them remains relatively constant. This gap is more evident in childhood when an individual is less able to exert control over his or her circumstances than in later life (Mannuzza et al., 1998).

Other social and neurodevelopmental changes occur as a child matures. Locomotor hyperactivity, which is the most visible characteristic of ADHD in young children, eventually decreases whether or not the condition is treated (Frick et al., 1994). Symptoms of inattention, by contrast, remain relatively constant (Hart et al., 1995) and in time become increasingly identifiable. Thus, many cases of Predominantly Inattentive Type ADHD (see Table 1) are not identified until the middle grades, or later.

Changes in brain anatomy and chemistry also are evident over time. Studies of brain chemistry have suggested that changes in the brain chemical dopamine may contribute to the physiology of ADHD (Castellanos, 1997). A recent study (Ernst et al., 1998) found evidence of decreased dopamine and/or norepinephrine neurons in the frontal lobes of the brain of adults who have ADHD. Researchers have also found that portions of the frontal lobes are smaller in children who have ADHD (Castellanos et al., 1996; Filipek et al., 1997). These neurochemical and neuroanatomic findings are consistent with the theory that the underlying cognitive deficits in ADHD are impairments in *executive functioning* (Denckla, 1989; Barkley, 1996; Denckla, 1996) which includes such processes as task analysis, strategy control and strategy monitoring. Impairments in these operations affect an individual's ability to inhibit and delay responses, initiate and sustain activity, set priorities, and organize, which are among the most salient traits of ADHD (Barkley, 1997).

While researchers have not yet definitively shown "what ADHD is," they have learned "what it is not." This distinction is crucial to the diagnostic process. Among the many psychiatric and medical conditions that may co-exist with ADHD or be confused with it are oppositional defiant disorder and conduct disorder (Quay, 1999), substance abuse and dependence (Biederman et al., 1997), learning disorders (Pliszka, 1998), tic disorders (Freeman, 1997), mood or anxiety disorders (Angold, Costello & Erkanli, 1999), post traumatic stress disorder (Famularo et al., 1996) and sleep disorders (Bowen, Fenton & Rappaport, 1991; Stein et al., 1996).

That such a broad array of conditions can mimic or accompany ADHD makes the assessment and diagnosis of the disorder problematic. In the next section we will present some of the best known assessment and identification instruments used for ADHD.

### How is ADHD Assessed and Diagnosed?

The current criteria for ADHD, taken from the fourth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV), the diagnostic 'bible' of the American Psychiatric Association (1994), are presented in Table 1. That these behavioral descriptions are inevitably subjective means that, even under research conditions, the repeated application of the criteria does not result in the same diagnosis 100% of the time. It is important to note that these criteria, like all those included in DSM-IV, are provisional and like any single diagnostic assessment, have an appreciable chance (at least 20–25%) of being incorrect (Lahey et al., 1994).

While this level of inaccuracy is undesirable, uncertainty has and always will accompany medical or psychological diagnoses. Errors in diagnosis, however, are bi-directional. Thus while some children have been misdiagnosed and treated for ADHD that was *not* present (false positives), many others have ADHD or specific learning disorders that have not been diagnosed (false negatives). For example, in a county-wide Tennessee sample, less than a third of children who were diagnosable with ADHD by teacher ratings had been so identified, and less than one quarter had been treated for the condition (Wolraich et al., 1998).

Gender also appears to affect identification. Epidemiological studies have confirmed that while most children with ADHD are male, a substantial fraction (25–30%) is female (Lahey et al., 1999). Yet the proportion of children who are referred for evaluation and treatment has remained 70–90% male (Gaub & Carlson, 1997).

We believe that the diagnosis of ADHD is also affected by giftedness. Silverman (1998) noted that some professionals erroneously assume that a child who demonstrates sustained attention, such as a gifted child who is occupied with an activity in a high-interest area, cannot have ADHD. The state of rapt attention,

Table 1. Diagnostic Criteria for Attention-Deficit/ Hyperactivity Disorder..

---

A. Either (1) or (2):

(1) six (or more) of the following symptoms of inattention have persisted for at least 6 months to a degree that is maladaptive and inconsistent with developmental level:

*Inattention*

- often fails to give close attention to details or makes careless mistakes in schoolwork, work, or other activities
- often has difficulty sustaining attention in tasks or play activities
- often does not seem to listen when spoken to directly
- often does not follow through on instructions and fails to finish schoolwork, chores, duties in the workplace (not due to oppositional behavior or failure to understand instructions)
- often has difficulty organizing tasks and activities
- often avoids, dislikes or is reluctant to engage in tasks that require sustained mental effort (such as schoolwork or homework)
- often loses things necessary for tasks or activities (e.g. toys, school assignments, pencils, books or tools)
- is often easily distracted by external stimuli
- is often forgetful in daily activities

(2) six (or more) of the following symptoms of hyperactivity-impulsivity have persisted for at least 6 months to a degree that is maladaptive and inconsistent with developmental level:

*Hyperactivity*

- often fidgets with hands or feet or squirms in seat
- often leaves seat in classroom or in other situations in which remaining seated is expected
- often runs about or climbs excessively in situations in which it is inappropriate (in adolescents or adults, may be limited to subjective feelings of restlessness)
- often has difficulty playing or engaging in leisure activities quietly
- is often 'on the go' or often acts as if 'driven by a motor'
- often talks excessively

*Impulsivity*

- often blurts out answers before questions have been completed
- often has difficulty awaiting turn
- often interrupts or intrudes on others (e.g. butts into conversations or games)

B. Some hyperactive-impulsive or inattentive symptoms that caused impairment were present before age 7 years

C. Some impairment from the symptoms is present in two or more settings (e.g. at school and at home).

D. There must be clear evidence of clinically significant impairment in social, academic or occupational functioning.

E. The symptoms do not occur exclusively during the course of a Pervasive Developmental Disorder, Schizophrenia, or other Psychotic Disorder and are not better accounted for by another mental disorder (e.g. Mood Disorder, Anxiety Disorder, Dissociative Disorder, or a Personality Disorder).

*Code based on type:*

314.01 Attention-Deficit/Hyperactivity Disorder, Combined Type- if both Criteria A1 and A2 are met for the past 6 months

314.00 Attention-Deficit/Hyperactivity Disorder, Predominantly Inattentive Type- if Criterion A1 is met but Criterion A2 is not met for the past 6 months

314.01 Attention-Deficit/Hyperactivity Disorder, Predominantly Hyperactive-impulsive Type: if Criterion A2 is met but Criterion A1 is not met for the past 6 months

---

sometimes referred to as 'flow' (Csikszentmihalyi, 1990), may also be described as 'hyperfocus', which individuals with ADHD frequently experience (Hallowell & Ratey, 1994a; Kaufmann, Kalbfleisch & Castellanos, 2000).

Activities that are continuously reinforcing, and 'automatic', such as video or computer games or reading for pleasure, do not distinguish children who have ADHD from controls, whereas effortful tasks do (Borcherding et al., 1988; Douglas & Parry, 1994;

Wigal et al., 1998a). By the nature of their giftedness, the range of tasks that are perceived as 'effortless' is broader for gifted children. However, ADHD is not characterized by an *inability* to sustain attention, but rather, by the inability to appropriately regulate the application of attention to tasks that are not intrinsically rewarding and/or that require effort. Such tasks are characteristic of much of the work that is required in school.

### Types of ADHD

Four subtypes of Attention-Deficit/Hyperactivity Disorder are recognized in the DSM-IV: Predominantly Hyperactive/Impulsive, Predominantly Inattentive, Combined, and Not Otherwise Specified (American Psychiatric Association, 1994). The criteria for each of these subtypes are presented in Table 1. In order to meet the criteria for one of the specific subtypes, at least six of the nine symptoms of hyperactivity/impulsivity, or at least six criteria from the nine symptoms of inattention must be present. (Combined type means both sets of criteria are met.) The symptoms must occur *in more than one setting*, must persist for *at least six months*, and must affect the individual "to a degree that is *maladaptive and inconsistent with developmental level* (p. 83).

We have italicized parts of the previous sentence to emphasize that attention deficit disorders cannot and should not be diagnosed on the basis of a few fleeting observations. That a child occasionally shows symptoms of hyperactivity at home or inattention in the classroom is insufficient to warrant a formal diagnosis. The diagnostic label ADHD should only be applied when many factors are considered over time in multiple settings and then, only with deliberate consideration.

### Impairment and Age-of-Onset

The diagnostic criteria for ADHD emphasize that "there must be clear evidence of *clinically significant impairment* in social, academic, or occupational functioning" (p. 84). Moreover, some impairing symptoms must be present before the age of seven. Several researchers (Applegate et al., 1997; Barkley & Biederman, 1997, 1998) have criticized the age criterion as being too limiting. Until this issue is resolved, however, the age criterion remains a requirement for the diagnosis.

### Diagnosis by Team

While the DSM-IV criteria can be used by anyone as a simple checklist, a diagnosis reached in this way has uncertain validity. In optimal circumstances a team, *including a qualified clinician*, such as a pediatrician, family physician, psychiatrist, neurologist or psychologist, should make the diagnosis because only specialists can assess the aforementioned physical and psychological problems that mimic ADHD. Informa-

tion about all these conditions is rarely available to school personnel, no matter how observant, experienced or well trained they may be.

Clinicians cannot function in a vacuum and therefore need assistance from parents and school personnel. A recent study (Barbarese & Olsen, 1998) revealed, however, that teachers receive only minimal information about ADHD in their undergraduate education. Therefore, until pre-service education programs offer more comprehensive training, school systems must assume responsibility for providing the relevant information. Opportunities to learn about such crucial issues as identification, assessment, legal rights, and educational interventions should be made available to school personnel, parents, and the community at large to ensure the effectiveness and efficiency of assessment and diagnostic procedures.

### The Teacher's Role in Assessment and Identification

Although most children with ADHD display their symptoms prior to reaching elementary school, the majority can be identified only when their behavior is observed and compared to other children over a sustained period of time. The classroom teacher, therefore, is professionally best suited to this task. When the child in question is gifted, an individual who specializes in giftedness should also be included in the process so the child's behavior can be compared to children of comparable abilities (Silverman, 1998). In all settings, however, appropriate identification instruments such as well-researched behavioral rating scales must be employed.

There are two types of rating scales for ADHD (Dykman, Ackerman & Raney, 1993). One type, which includes such instruments as the Child Behavior Checklist (for parents) and the Teacher Report Form (Achenbach & Edelbrock, 1983), is designed to assess a wide range of behaviors and symptoms. The strengths of these instruments are that they have large normalization samples, and require open-ended observations about the child's strengths and the adult's areas of greatest concern. Their weakness is that they are not constructed with reference to any particular diagnostic system.

The other category of rating scale focuses on a narrower range of behaviors or symptoms. The earliest of these, devised by Conners (Goyette, Conners & Ulrich, 1978), has been widely used in research and clinical settings for over two decades. The most recent revisions have been re-normed and are now compatible with DSM-IV diagnostic criteria for ADHD for children, adolescents, and adults (Conners, 1997). Other rating scales that are widely used to diagnose ADHD and to track treatment progress include the Attention Deficit Disorder Evaluation Scale (ADDES) (Bussing et al., 1998), the SKAMP (Wigal et al., 1998b), the Behavior Assessment System for Children

(BASC) (Vaughn *et al.*, 1997), and the Adolescent Behavior Checklist (Adams, Kelly & McCarthy, 1997).

All rating scales include separate age-related norms for males and females because the population means differ for boys and girls (Gaub & Carlson, 1997). Also, within the Conners normalization sample, teacher ratings of African Americans are higher than for comparison subjects (Epstein *et al.*, 1998). Unfortunately, no normalization samples among other sub-populations, including the gifted, exist. Although rating scales can identify ADHD, they are inherently subjective and minor differences in rating scales can lead to different results. Trained personnel, therefore, remain the crucial component in the evaluation process.

New neuroimaging tools such as positron emission tomography (PET) (Zametkin *et al.*, 1990; Ernst *et al.*, 1998), single photon emission computed tomography (SPECT) (Lou *et al.*, 1998), and magnetic resonance imaging (MRI) (Castellanos *et al.*, 1996; Filipek *et al.*, 1997; Vaidya *et al.*, 1998) are currently being used in research studies and may eventually generate new means of diagnosing ADHD. But even these sophisticated techniques are insufficient to address the key issue of ADHD in relation to giftedness that is the focus of this chapter.

### ADHD or Gifted?

In recent years, several authors (Lind, 1993; Webb & Latimer, 1993; Cramond, 1995; Freed & Parsons, 1997; Tucker & Hafenstein, 1997; Baum, Olenchak & Owen, 1998) have expressed concern that giftedness is often misconstrued as ADHD. In the absence of relevant data, we accept the possibility of occasional over-diagnosis among gifted children. However, it is worth noting that there is no evidence of substantial over-diagnosis of ADHD among the general population (Goldman *et al.*, 1998).

While a misdiagnosis of ADHD is clearly undesirable, another diagnostic error may be even more prevalent among gifted students. This difficulty occurs when a student's over-reliance on strengths inadvertently obscures the disability. While this strategy may highlight a student's gifts, it does not eliminate the reality of the impairment, which is likely to reveal itself at some point in the student's development. On the other hand, if a student is allowed to acknowledge and experience the disability, he or she may learn appropriate compensatory or coping skills. Accepting that a child can be both gifted and ADHD and exploring the ways in which these conditions interact in each individual would seem to be a more productive way of looking at the problem than agonizing about a false dichotomy.

Sternberg's (1986) componential theory of intelligence, though not intended for this purpose, provides one way of describing the interaction between gifted-

ness and ADHD. This model suggests three components related to mental processes: knowledge-acquisition components (processes used in learning new material), metacomponents (higher-order processes used in planning, monitoring and decision making), and performance components (processes used in executing a task.)

For the purposes of this discussion, we have adapted this triarchy into the three stages of *input*, *processing*, and *output*. In this model, the *input stage* refers to the processes required for taking information in—listening, reading, kinesthetic learning, etc.; this stage corresponds to knowledge-acquisition. Learning disabilities, such as reading disorder (often called dyslexia), presumably have their greatest effects at this stage.

*Processing* refers to what happens 'in the head' of the thinker and would be roughly analogous to some metacomponents. While definitions of intelligence are controversial, most theories acknowledge that gifted individuals have an exceptionally rich set of mental links within which to embed new knowledge. It is at this stage, then, that giftedness has its greatest impact.

While ADHD can influence the input and processing stages, the most pronounced effect of the symptoms typically occur in the *output* or performance stage (Sergeant, Oosterlaan & Van der Meere, 1999). Until this stage, gifted/ADHD students may appear similar to other gifted students in terms of the amount of information they take in and process. Unlike other gifted students, however, they cannot summon their resources effectively and consistently at the output stage. This causes problems for the student who tries to produce written work because he or she is unable to process linearly the large amount of disparate information that were previously acquired. Oral communication, on the other hand, enables students with ADHD to reveal the extent of their knowledge through multiple channels such as tone of voice, facial expression, body and hand gestures, eye contact and intensity.

The contention that ADHD is merely misdiagnosed giftedness is likely derived from prematurely assessing the gifted student during the input and processing stages. Therefore, when evaluating ADHD in a student who is gifted, teachers should observe the quality and effectiveness of *all* stages of a student's learning.

Given the realities of the co-existence of giftedness and ADHD, 'ADHD or gifted?' is a less critical question than 'how impaired is a student by ADHD?' Some children are able to compensate in most situations for their susceptibility to ADHD; others are seriously handicapped. The former would not be diagnosed with ADHD as per the DSM-IV if they did not manifest impairment. Therefore, the single most relevant element that must be considered in evaluating ADHD is the degree of *impairment* a child experiences as a result of his or her behaviors.

A child who is far enough on the continuum of ADHD-like behaviors to be impaired academically, interpersonally, or in the development of sense of self, should be examined from a clinical/medical perspective to exclude treatable conditions and to distinguish ADHD from more benign 'overexcitabilities' (Silverman, 1993; Piechowski, 1997) and other temperamental or psychological traits. However, this does not mean that every child who may be somewhat impaired needs medical evaluation. As many authors (Hartmann, 1993; Lerner, Lowenthal & Lerner, 1995; Diller, 1998; Flick, 1998) have noted, non-medical interventions can be used within the school and home and should be tried before more intrusive interventions are employed.

### What is the Treatment for ADHD?

A comprehensive treatment plan for children with ADHD includes counseling, behavior management, educational modifications and, in cases where these do not suffice, medication. For the purposes of this chapter, however, we will limit our discussion to those issues that are most relevant to education and to gifted students in particular.

#### *Educational Interventions*

Once again, we must acknowledge the lack of data pertinent to gifted children. We also must limit our review of general educational accommodations. However, several resources (Hartmann, 1993; Hallowell & Ratey, 1994b; Lerner, Lowenthal & Lerner, 1995; Diller, 1998; Flick, 1998; Wiggins, 1998) provide more in-depth information about classroom organization, curriculum modification, behavior management, listening and memory techniques, social skills training and time management.

Generally speaking, the best educational programs for students with ADHD are based on structure, stimulation, and individualization (Lerner, Lowenthal & Lerner, 1995; Flick, 1998). While these are similar to qualities found in programs for the gifted (VanTassel Baska, 1997), this does not mean that a student's placement in a gifted program precludes further accommodations. In a program that stresses gifts, talents, and creativity (Renzulli & Reis, 1997), the student's need for ancillary services may be inadvertently camouflaged. An optimal program, therefore, should provide *complexity* and *challenge* to nurture a student's gifts and *support* and *structure* to accommodate the ADHD.

This duality presents immense challenge to educators, especially in light of the dearth of well-researched models designed specifically for this purpose. Of the models currently available in general education, we believe that those emphasizing diverse types of learning and production (Gardner, 1991; Renzulli, 1994; Kaplan & Gould, 1995; Sternberg et al., 1996) are the most promising for gifted students with ADHD

because they acknowledge and support many ways in which students can be productive and successful.

The information in the following chart demonstrates how common instructional practices from the lexicon of gifted child education might be modified for ADHD (Kaufmann, Kalbfleisch & Castellanos, 2000). The strategies listed in column one are representative of those frequently recommended for students with ADHD; column two specifies techniques and activities commonly used in gifted child education. The third column suggests ways in which the two might be combined to effectively teach gifted children with ADHD. While these suggestions cannot be construed as a curriculum or program, they do provide a springboard for application and research.

Although classroom modifications are important, the most significant school-based adjustment must be in the attitudes of educators. Teachers and students alike must learn to cope with giftedness (Galbraith & Delisle, 1996; Colangelo, 1997) and ADHD (Stern & Ben-Ami, 1998) and learn how each condition can enhance or inhibit the other. Educators should also be willing to substitute multi-modal assessment tasks for traditional evaluation techniques to more accurately identify a child's true range of abilities and interests (Renzulli, 1994; Wiggins, 1998). Finally, educators must change their definitions of success to reflect process and diversity in addition to conventional indications of achievement (Tomlinson, Callahan & Lelli, 1997; Flick, 1998).

Even in the best educational environment, however, with the most informed and flexible teachers, most students who have ADHD, including gifted students, require additional help. While non-medical interventions have their strong proponents (Lerner, Lowenthal & Lerner, 1995; Flick, 1998), medication remains the most well-researched and commonly recommended mode of treatment for ADHD in the United States.

#### *Medical Interventions*

The issue of medications and attention deficit disorders is too complex and contentious to be adequately addressed in a chapter, especially in light of the present emphasis on giftedness. However, certain information about stimulant medications, their possible benefits, and side effects should be mentioned.

Extensive research has repeatedly shown that psychostimulants such as methylphenidate (Ritalin) and the amphetamines (Dexedrine and Adderall) (Swanson et al., 1993) are remarkably safe and effective treatments for ADHD in the short-term. These drugs, which act by increasing the amount of the neurotransmitters dopamine and norepinephrine, have significant short-term benefits in about 70% to 80% of children who have ADHD (Spencer et al., 1996) with a slightly lower positive response rate in children who have Predominantly Inattentive Type ADHD. The benefits of these

Standard Modification for Students with ADHD	Standard Instructional Strategy from Gifted Child Education	Modified Instructional Strategy for Gifted Students with ADHD
To increase sustained attention, break complicated tasks into smaller parts to be completed at different times.	Synecotics (Gordon, 1960; Gordon, 1974; Gordon & Poze, 1972)	Present Synectics stages in isolation rather than teach the entire process at one time.
To improve listening ability, use visual aids.	Creative/Future Problem Solving (Eberle & Stanish, 1985; Isaksen & Treffinger, 1985; Torrance & Sisk, 1997)	Write the rules and vocabulary of CPS/FPS on a poster or cue cards and refer to them often rather than rely solely on verbal instructions.
To minimize distractions, announce transitions in advance of their occurrence.	Creative/Future Problem Solving, Synectics	Announce each stage of the process before moving to the next.
To promote performance, use a buddy system in which students assist each other in concluding the day's work and reviewing the requirements for the next day.	Enrichment Clusters (Renzulli, 1994; Renzulli & Reis, 1997)	Assign buddies within each enrichment cluster, as well as in the student's regular classroom.
To cultivate organizational skills, provide a schedule so that the student knows exactly what to do for each class period.	Curriculum Compacting (Reis, Burns & Renzulli, 1993; Renzulli, 1994)	Create and identify daily compacting procedures in addition to or instead of longer-term goals.
To encourage performance, promote the use of tape recorders, computers, word processor and other technological advances.	Mentorships (Clasen & Clasen, 1997; Noller & Frey, 1994)	Employ alternative types of mentorships, e.g. on-line, correspondence, video, etc., rather than rely exclusively on in-person relationships.
To improve listening ability, eliminate extraneous noise and visual stimulation whenever possible.	Independent study (Betts, 1991; Kaplan & Gould, 1995; Schlichter, 1997)	Create a 'quiet area' for student-teacher conferences rather than hold meetings at the teacher's desk or in other high-traffic area.
To promote socialization, teach students effective communication skills that will generalize to a variety of situations.	Type III activities (Reis, Burns & Renzulli, 1993; Renzulli, 1994)	Encourage students to present their work to a variety of audiences rather than limit themselves to one type of audience.
To develop pro-social behavior, create a list of behaviors to be ignored as well as alternative behaviors.	Bibliotherapy (Frasier & McCannon, 1999; Schlichter, 1997)	Present biographies of eminent persons and fictitious gifted characters focusing on learning and problem solving instead of emphasizing success, e.g. process vs. product.
To encourage persistence, help students identify environmental distracters.	Guided fantasy (Eberle, 1996; Torrance & Safter, 1999)	Guide students through a Perfect Day Fantasy, allowing them to identify those factors that interfere with their goals.
To help students understand the consequences of their behavior, use appropriate reinforcers.	Interest inventories (Renzulli, 1977)	Allow students to select challenging, high-interest rewards such as reading or puzzles as well as standard reinforcers such as food or stickers.

medicines include a reduction of the core symptoms of inattention, impulsivity and hyperactivity, as well as improvement in motor, social and emotional functioning.

When these symptoms are reduced or eliminated, other improvements in classroom learning and productivity (Douglas et al., 1988; Balthazor, Wagner & Pelham, Jr., 1991), short term memory (Swanson et al.,

1978), interactions with parents, teachers and peers (Barkley et al., 1984; Pelham et al., 1985), and perceptual efficiency (Rapport et al., 1986), can also occur. At the same time, the most robust effects are on behavioral symptom ratings (Swanson et al., 1993). Although stimulants produce mild to moderate side effects, such as appetite suppression, headaches, irritability and trouble falling asleep, these usually subside when the prescribing physician changes the timing, dosage or formulation of the drug (Miller & Castellanos, 1998). For most children, however, the benefits of improved functioning in school, at home and with peers outweigh the temporary discomfort of side effects.

The recent increase in the prescription of stimulant medications, particularly in the U.S., has caused alarm and incited headlines worldwide. Studies of trends in prescriptions indicate that this pattern is not due to unscrupulous prescribing or illegal diversion but to increased treatment of previously neglected groups such as girls and children with Predominantly Inattentive ADHD (Goldman et al., 1998). Other explanatory factors for the increase in prescriptions are that treatment with medications is now being extended longer into adolescence and young adulthood and is more likely to be administered daily and year round, instead of just during school hours (Safer & Krager, 1994).

The long-term effects of stimulants appear to be relatively benign, although one longitudinal study raised the possibility that childhood use of stimulant medications may be associated with a later increased risk of smoking and stimulant abuse beyond that expected from ADHD alone (Lambert & Hartsough, 1998) although other investigators found that stimulant medications decrease the later risk of substance abuse (Biederman et al., 1999; Paternite et al., 1999). Since stimulant medications do not 'cure' ADHD and are not absolutely risk-free, their use should be reserved for those individuals who are significantly impaired and for whom psychosocial and behavioral programs and significant academic accommodations have not provided adequate benefit (Overmeyer & Taylor, 1999). Based on the most extensive randomized controlled trial of treatment modalities in ADHD (Jensen et al., 1999), Taylor argued that even in a low-medication culture, such as in most European countries, "children with suboptimal responses to behavioral approaches should be offered medication as well" (p. 1097, Taylor, 1999).

### Conclusion

Clearly, this chapter must conclude with a plea for empirical research on giftedness and attention deficit disorders as no such data currently exist. A simple but profoundly important question such as the incidence of DSM-IV subtypes of ADHD among the gifted must be investigated. If research were to show that current

DSM-IV criteria identify significantly different proportions of gifted students compared to the general population, subsequent studies would be able to explore the sources of such discrepancies. The existence of data would in turn facilitate and encourage the development of strategies for appropriate identification and curriculum development.

Although we have focused on the negative aspects of ADHD in this chapter, we do not believe that ADHD is a defect that must be 'cured'. In fact, we have often observed that ADHD can enhance as well as inhibit the realization of gifts and talents.

Educators of gifted students with ADHD face a formidable task in that they must provide opportunities for students to apply their strengths while ameliorating their deficits. Although the same might be said of any sound educational program, this is more daunting for gifted students with ADHD because of the disparity these conditions can create. Only through consistent attention, immeasurable creativity and patient understanding by educators, parents and students, coupled with substantive research will these challenges be adequately addressed.

# Gender Differences in Engineering and the Physical Sciences Among the Gifted: An Inorganic-Organic Distinction

David Lubinski<sup>1</sup>, Camilla P. Benbow<sup>2</sup> and Martha J. Morelock<sup>3</sup>

## Introduction

Beginning in 1968 and essentially complete by 1972, there was in the U.S. a legal revolution in women's education and employment rights (Rossiter, 1995); it promised in the U.S. broad ramifications for women's careers across a wide range of professions. Over the ensuing three decades, many of the unenlightened barriers preventing women from achieving educational credentials and occupational status commensurate with their abilities were removed. In many educational programs, gender representation began to approach parity. Just as the protagonists urging the removal of the aforementioned barriers had predicted would occur, women entering the field of Law, for example, exhibited exceptional performances on bar exams and achieved high grades and honors in their classes. In 1995, 29.5% of the doctorate degrees earned in Law and legal studies in the U.S. went to women, up from less than 1% of doctorate degrees awarded to women in 1971 (U.S. Bureau of the Census, 1998).

The health and social sciences also saw striking gains in the U.S. Of the doctorate degrees awarded in health sciences in 1995, 58.1% went to women—up from 16.5% in 1971. Of the doctorate degrees awarded in social sciences in 1995, 37.7% went to women; whereas only 13.9% went to women in 1971. In psychology, women accounted for 62.6% of the doctorates awarded in 1995, up from the 24% of awarded doctorates credited to them in 1971.

This trend served to reinforce further the well-grounded arguments for removing gender-discriminating educational barriers. Arguments originally stemming primarily from political-ideological concerns now became buttressed by economic and psychological justification: not only were women

performing admirably in these areas, the disciplines themselves were benefiting from a more able student population. The optimism spawned by these changes is reflected in a 1988 text: "A transformation is underway . . . fueled by feminist concerns and by the entry of increasing numbers of women into the scientific professions" (Lips, 1988).

When one looks at inorganic scientific fields, however, a marked winnowing of the male/female ratio is not observed. Despite gains, the participation of women in the physical sciences, mathematics, and engineering reflects a persistent gender disparity (National Science Foundation, 1999). For example, 1 in 6, or 17%, of engineering *bachelor's* degrees were awarded to women in 1995 (still, an increase from the less than 1% of the total in 1966). And women were awarded 35% of the *bachelor's* degrees in mathematics and computer science in 1995—only a slight increase over 1966.

At the graduate level, 23.5% of awarded Doctorates in physical sciences and science technologies went to women in 1995, up from 5.6% in 1971. In mathematics, women accounted for 22.1% of the awarded Doctorates in 1995, having been credited with 7.6% in 1971. The smallest proportion of women doctorate recipients in any broad field was in engineering. While men earned 5,313 engineering doctoral degrees in 1995, women earned 694 engineering degrees—just 12% of the total engineering doctorates. Even so, this represented a notable increase over the 7% of engineering doctorates awarded to women in 1985 (National Science Foundation, 1999) and the 0.6% of doctorates in engineering and engineering technology awarded to women in 1971 (U.S. Bureau of the Census, 1998).

Why has such gender disparity persisted in engineering and the physical sciences? Have we completely removed from these disciplines the barriers that previously prevented women from entering other fields, such as law and medicine? Are there factors unique to engineering and the physical sciences that discourage women from entering and excelling within

them? These questions, among many others, are being investigated through our research. Here we focus specifically on factors related to educational/vocational choice, exceptional educational/vocational achievement, and gender differences in educational and vocational outcomes within the gifted population. Our research, however, is also aimed at experimentation with and refinement of well-known educational interventions. That is, in working with intellectually talented students, individually and in groups, we attempt to find and provide environments wherein their talents can best blossom and come to their full fruition. Understanding what constitutes those environments and learning how to create them are two of the more central goals of our applied research (Lubinski & Benbow, 2000); we shall draw upon that work as well.

Our work with mathematically and verbally precocious youth is particularly relevant to exploring the critical determinants of gender differences in advanced achievement. Noteworthy professional achievements in the sciences tend to be within the exclusive purview of the highly able—people located within the top few percentage points of the distribution of intelligence. Thus, our Study of Mathematically Precocious Youth (SMPY) provides a data bank especially well suited to speak to male/female differences in educational achievement and vocational choice, inasmuch as it contains large proportions of individuals, of both genders, who possess the intellectual potential for achieving excellence in engineering, mathematics and the physical sciences, as well as for a variety of other intellectually demanding careers.

Our empirical studies have indeed revealed unique factors operating to preserve gender-disparities in inorganic vs. organic disciplines. Instead of stemming solely from external, culturally imposed barriers to vocational and educational opportunities, however, these factors appear to be more related to personal choice. Our empirical findings lead us to propose here that gender differences in achievement are a reflection of such choices. Furthermore, these choices naturally emerge from a number of longitudinally-stable, gender-differentiating attributes critical for a commitment to, and excellence in, contrasting careers.

It is the thesis of this chapter that the theoretical model guiding our research on the optimal development of intellectual talent (which we will explicate) has implications for analyzing and better understanding gender differences in various careers. Our model addresses why some intellectually demanding disciplines and occupations are over-represented by women, while others are over-represented by men. We suggest that it might be profitable to reconceptualize the professional and the public view of gender differences in maths/science achievement, namely, as consequences of the different perspectives and personal qualities those males and females bring to situations. It is our view that too much negativity has been attached

to the under-representation of women in the physical sciences, as if women possessed a deficit of some kind because, naturally, more females should be interested in such career possibilities. It is our position that young adults (particularly intellectually gifted young adults) are in a better position to make informed decisions on their personal development than some theorists give them credit for. To be sure, educators and policy makers should ensure opportunities for all students to develop as fully as their abilities and motivations take them. But if this results in some disciplines being over-represented by men, while others are over-represented by women, we are not as concerned, especially when the overall proportion of advanced educational degrees are comparable for men and women (Benbow et al., 2000; Lubinski et al., in press).

To illustrate how this might be accomplished, we shall draw on findings from SMPY to document gender differences in key antecedents to educational and vocational choice. We shall first describe the design of our study and its theoretical framework; this is followed by a discussion of gender differences in particular kinds of achievement among the mathematically talented. Some empirical findings involving gender differences on familiar as well as neglected variables critical for choosing contrasting educational and vocational paths are reviewed. Finally, we close with a brief discussion of the implications of our current state of knowledge and how these implications might be used to both guide and organize the direction of future research on the intellectually gifted.

### **Study of Mathematically Precocious Youth (SMPY)**

SMPY was founded by Julian C. Stanley in September 1971 at Johns Hopkins University and predicated on the philosophy of conducting research through service to intellectually talented students. SMPY was interested in first identifying adolescents who possess exceptional intellectual abilities and, then, to ascertain factors that contribute to their optimal educational and vocational development. Yet, special attention has always been devoted to maths/science disciplines. One intervention, implemented from the start, was to provide these students, through acceleration and special classes, with better opportunities to develop their already exceptional quantitative skills, which we have now referred to as *appropriate developmental placement* (Lubinski & Benbow, 2000). To facilitate the uncovering of other beneficial interventions and to answer basic research questions about intellectual giftedness more generally, SMPY established in 1972 a planned 50-year longitudinal study, now being conducted at Vanderbilt University. Through this study, which currently includes over 5000 talented individuals identified over approximately a 20-year period, SMPY is beginning to bring into focus the factors contributing to gifted students' educational, intellectual, personal, and vocational development (Lubinski & Benbow,

1994, 2000; Benbow, Lubinski & Suchy, 1996; Stanley, 1996).

Participants in SMPY were identified through a talent search, a concept developed by Stanley and initially limited to mathematical talent (Keating & Stanley, 1972; Stanley, 1973; Stanley, Keating & Fox, 1974; cf. Cohn, 1991). The concept of a talent search has been refined over the past three decades and extended from 450 students in 1972 to well over 200,000 on an annual basis and from a focus on mathematics only to include verbal and overall intellectual abilities. Yet the basic premise of the talent search has remained the same: students in 7th or 8th grade (12- to 13-year-olds) who are already known to have scored in the top 3% on national norms on standardized achievement tests (e.g. the Iowa Test of Basic Skills) administered routinely by American schools are invited to take the College Board Scholastic Aptitude Test (SAT) [now the Scholastic Assessment Test] or, in some places, the ACT at regular administrations. The SAT measures mathematical reasoning (SAT-M) and verbal reasoning (SAT-V) ability and is designed for 11th and 12th graders who plan to attend college. This form of assessment is known as above-level testing (Stanley, 1990; Benbow & Stanley, 1996), inasmuch as the SAT was designed for students 4 to 5 years older than SMPY participants. Nonetheless, the score distributions manifested by these gifted 7th or 8th graders are similar to those observed in random samples of high school students (Keating & Stanley, 1972; Benbow, 1988). It is through this mechanism—the talent search—that the SMPY subject pool for the longitudinal study was formed. All 5000+ subjects, except for one group, were selected for high SAT scores placing them in at least the top 1% in intellectual

ability. Although several 'types' of gifted students are being studied, a dominant emphasis has remained on the maths/science disciplines.

Four SMPY cohorts of gifted students, initially identified at age 13, are being tracked longitudinally, as well as a fifth cohort comprised of graduate students in this nation's top math/science departments (see Table 1). Each cohort is separated by a few years. Collectively, the five cohorts span 25 years. Because the students in the first four cohorts were identified over a 25-year period, using the same criteria, our design allows us to assess historical influences to a degree (cf. Grinder, 1985). This is a great advantage; lack of historical control is a problem associated with most longitudinal studies.

Thus, over 5000 students are currently participating in the SMPY longitudinal study; all of the students in the five cohorts are being surveyed at critical junctures throughout their youth and adult lives. Moreover, each cohort will be surveyed at the same age to ensure developmental comparability of our cross-cohort findings. This serves as a rough sketch of the SMPY database and how it was constructed. Let us conclude this section by saying that, alas, SMPY is becoming more of a misnomer with time, inasmuch as many of our participants are now approaching age 40 and, since the early 1980s, just as much emphasis has been placed on identifying verbally talented youth as mathematically talented youth. Time is demanding that we do something about our initially appropriate but no longer descriptively apt name of SMPY.

### Theoretical Structure Guiding SMPY Research

The conceptual framework for our research is explicated in (Lubinski & Benbow, 2000); it draws heavily

Table 1. The SMPY Longitudinal Study.

Cohort	N	When Identified	Age when Identified	SAT criteria	Ability level %
1	2188	1972–1974	12–13	Verb $\geq$ 370 or Math $\geq$ 390	1
2	778	1976–1979	12	Top 1/3 of Talent Search Participants	0.5
3	423	1980–1983	< 13	Math $\geq$ 700 Verb. $\geq$ 630	0.01
		1983	12	SAT-M + SAT-V $\leq$ 540	5
		Comparison Groups			
		1982	12	500–590 SAT-M 600–690 SAT-M	0.5
4	$\approx$ 1500	1987	12	Math $\geq$ 500 or Verb. $\geq$ 430	0.5

Note. A fifth cohort, Cohort 5 includes 750 students enrolled in top-ranked graduate departments in the U.S. in various math-science disciplines; they were surveyed at age 23–25 in 1992 (Lubinski et al., under review).

from findings on individual differences, which cut across educational, counseling, and industrial psychological contexts. Primarily, our work is based upon a well-known model of vocational adjustment (Fig. 1), the Theory of Work Adjustment (TWA), a model that has been developed by Rene V. Dawis and (the late) Lloyd H. Lofquist (Lofquist & Dawis, 1969, 1991; Dawis & Lofquist, 1984). An especially attractive feature of TWA is that it extends to critical antecedents of vocational adjustment (e.g. choosing a college major).

According to TWA, to assess optimal learning and work environments it is useful to parse an individual's work personality and the environment into two broad, but complementary, subdomains. An individual's work personality is primarily defined by two components: (1) repertoire of specific skills or abilities and (2) personal preferences for content found in contrasting educational/vocational environments. Similarly, different environmental contexts (educational curricula and occupations) are defined by: (1) their ability requirements and (2) the nature of their reinforcement capabilities. Optimal learning and work environments are then viewed as requiring two levels of correspondence, *satisfactoriness* and *satisfaction*.

Satisfactoriness denotes correspondence between abilities and the ability requirements of a particular environment (viz., occupation or educational curriculum), whereas satisfaction denotes correspondence between the preferences and the types of reinforcers provided by an occupation or educational track. Collectively, satisfactoriness (how the environment

will respond to the individual) and satisfaction (how the individual is likely to respond to the environment) are useful for predicting the length of time individuals remain in various educational or career tracks. They are continuous as opposed to discrete concepts and one's psychological adjustment to any given environment at any point in time is, to a large degree, a joint function of these two broad correspondence dimensions (see Fig. 1). One implication of the model is that assessing the environment (for its requirements and reward capabilities) is just as important as assessing the individual's learning and work personality (i.e. abilities and preferences). TWA also stresses the importance of assessing *both* abilities and preferences *concurrently* to ascertain the readiness of a given individual for a particular educational or career track (Lubinski, 1996, 2000). Next we turn to the particulars of the individual-differences constructs relevant to this model (see Fig. 1).

*Personality Structure: Critical Dispositions for Learning Readiness and Efficient Work*

**Abilities**

How are intellectual abilities best conceptualized? There is actually a remarkable consensus that intellectual abilities are nicely outlined by Guttman's (1954) early formulation of the Radex (Humphreys, 1979; Snow et al., 1984, 1996; cf. Ackerman, 1987; Lubinski & Dawis, 1992; Carroll, 1993); a Radex representation of intellectual abilities, taken from Snow's work, is provided in Fig. 1 (upper left). In this organization, cognitive abilities are differentiated along two dimen-

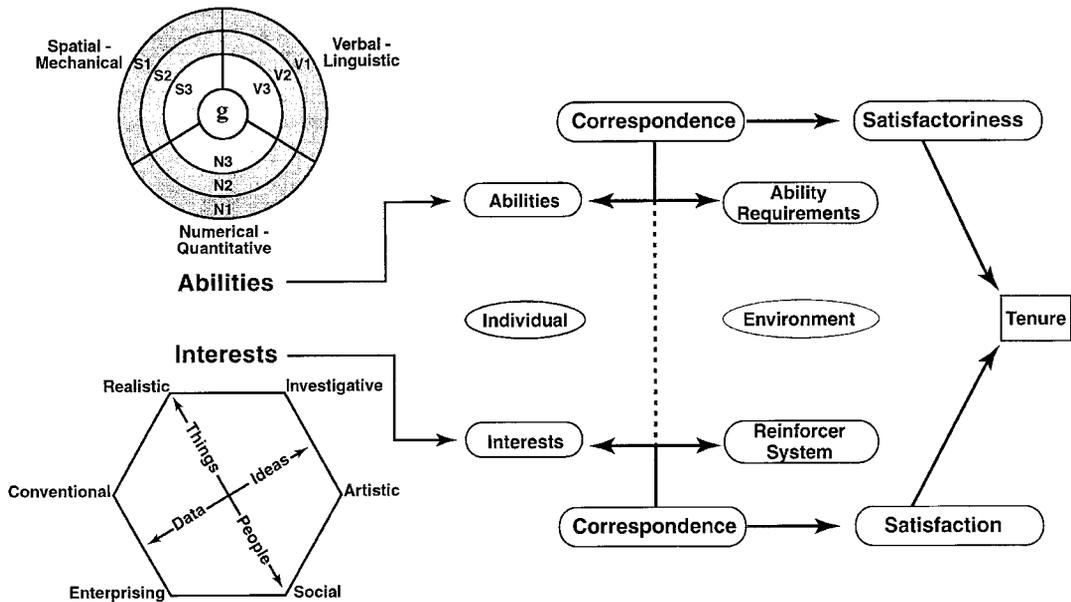

Figure 1. Theory of Work Adjustment

sions, *complexity* (viz., sophistication of the intellectual repertoire, general intelligence, or *g*) and *content* (viz., lower-order factors composed of three relatively distinct symbolic systems: verbal/linguistic, numerical/quantitative and spatial/pictorial). Both level and pattern are important to assess. In our work with the gifted, for example, we have found it useful to assess the complexity dimension to determine the extent to which educational acceleration is warranted (to provide a more correspondent learning environment), plus lower-order factors to ascertain the precise nature of the *appropriate developmental placement* required (thus providing a more individualized and optimal learning environment, responsive to students' unique strengths). Different 'types' of gifted students, for example, verbally vs. mathematically precocious, assimilate certain course work at different rates and more learning occurs when curricula are responsive to such individual differences (Benbow & Stanley, 1996; Lubinski & Benbow, 2000).

#### Preferences

In our research (and as part of our summer programs), the assessment of personal preferences is teamed with ability assessment to paint a more comprehensive picture of the unique aspects of each student; and counseling is based on how these distinct personality dimensions might form constellations, which factor into educational and career decision-making. Often students find this information useful in considering educational and career possibilities with counselors, teachers, and parents. Probably the most useful model for analyzing educational/vocational preferences is Holland's (1985) hexagonal structure, consisting of Realistic, Investigative, Artistic, Social, Enterprising, and Conventional interests (see Fig. 1, lower left). RIASEC is certainly the most widely used model in educational-vocational practice and research (Savickas & Spokane, 1999), and its cross-cultural generality has recently received empirical support (Day & Rounds, 1998).

We assess these normative attributes for identifying optimal learning environments (those likely to be most enjoyable and rewarding) for gifted students of comparable abilities, but who differ in non-intellectual attributes ultimately related to career choice. Our use of preference assessments is supported by empirical investigations, showing that preferences are sufficiently crystallized in the gifted by early adolescence to carry some applied utility. Lubinski, Benbow & Ryan (1995) provided evidence for the longitudinal stability of the Strong Interest Inventory (Hansen & Campbell, 1985) over a 15-year interval (ages 13–28); and, using an independent sample, Lubinski, Schmidt & Benbow (1996) documented the longitudinal stability of Allport, Vernon & Lindzey's (1970) Study of Values (SOV) over a 20-year interval (ages 13–33). Schmidt, Lubinski & Benbow (1998) added to this literature by

documenting the construct validity of the Strong for intellectually talented young adolescents. A wide range of individual differences is displayed by gifted young adolescents on the Strong (Harmon et al., 1994), which incorporates Holland's hexagon (Achter, Lubinski & Benbow, 1996). This suggests that these instruments—like the SAT used to sort out the wide range of abilities represented within the upper 1% of mathematical talent among 13-year-olds—might be useful for sorting out individual differences in motivational attributes among this special population.

Finally, additional empirical support for preference assessment with this special population was provided through a discriminant function analysis of educational outcomes (Achter, Lubinski, Benbow & Sanjani, 1999). A sample of 432 SMPY participants, assessed with both the SAT and the SOV during the 1970s, at or before age 13, were followed up 10 years later and asked about the areas in which they had earned their 4-year degree. These majors were then categorized into three groups: 'humanities', 'maths-science' and 'other'. Two discriminant functions significantly discriminated these three groups, with both the SAT and the SOV adding incremental validity relative to each other (Fig. 2). These two discriminant functions accounted for 23% of the variation between the three groups, which is amazing given the amount of within group heterogeneity. When abilities were initially entered, they accounted for 11% of group membership variance; when the SOV measures were added, an additional 12% of the variance was accounted for. Moreover, the functions clearly reveal support for the psychological reality of C. P. Snow's (1967) 'two cultures', the humanists (high-verbal abilities, high-aesthetic preferences) and the scientists (high-mathematical abilities, high-theoretical, low-social, low-religious); the authors discuss these functions in some detail. The point here is that abilities and preferences can be coordinated to better tailor learning opportunities (or select more correspondent learning niches) for each student based on the salient features of their (intellectual and motivational) individuality.

#### *Environment Structure: Assessing Critical Features of Environmental Ecologies for Learning and Work*

Up to this point we have talked about the personality structure of the individual (abilities and preferences); school and work environments can also be analyzed using analogous dimensions. Educational/vocational environments may be construed as molecular ecologies defined by: (1) their capability to reinforce certain preferences, and (2) the response requirements (or the abilities) that they demand of individuals. In engineering and the physical sciences, the response requirements particularly involve high mathematical and spatial/mechanical reasoning abilities, while investigative interests and theoretical values are among the most salient personal preferences for gravitating

toward scientific environments, finding the content of these disciplines reinforcing (for developing one's intellectual talent) and maintaining a commitment toward such disciplines (Roe, 1953; MacKinnon, 1962; Southern & Plant, 1968; Dawis & Lofquist, 1984; Holland, 1985; Lubinski & Benbow, 1992). These environments require intense abilities and preferences for manipulating and working with sophisticated things and gadgets for lengthy periods of time. Individuals with pronounced or relatively higher social values (or stronger need for people contact), in contrast, are not as readily reinforced in such environments.

The above is what many have found to be the person-environment correspondence structure for engineering and the physical sciences (Roe, 1953; Dawis & Lofquist, 1984; Holland, 1985; Dawis, 1991; Lubinski & Benbow, 1992; Lubinski et al., under review). Although students are not formally selected for advanced scientific training based on their theoretical values, their investigative interests, or their spatial and mechanical reasoning abilities (but they are on mathematical reasoning ability), they appear to self-select scientific careers based on all of these attributes, whether they are explicitly aware of their abilities and preferences or not (Humphreys, Lubinski & Yao,

1993). Moreover, an individual will remain in the sciences to the extent that congruence is established between: (1) his/her abilities and preferences, and (2) the skill requirements and reinforcers provided by the scientific environment, respectively. Satisfaction (need-reinforcer correspondence) and satisfactoriness (ability-ability requirement correspondence) are essential for optimal intellectual development; helping individuals achieve both is the central goal of SMPY's programmatic work with gifted youth.

**Optimal Educational Correspondence for the Extremely Gifted**

A proper response to this topic requires, first of all, a full appreciation of the range of interventions that need to be considered when creating optimal learning environments for the exceptionally gifted (Benbow & Stanley, 1996; Lubinski, Webb, Morelock & Benbow, in press). That is, if giftedness is arbitrarily defined as being in the top 1%, individual differences in IQs among the gifted range from approximately 135 to over 200 (roughly one-third of the entire IQ range). Paralleling this vast ability range is an equally wide spectrum of ideal learning environments. Because learning environments can range from discorrespon-

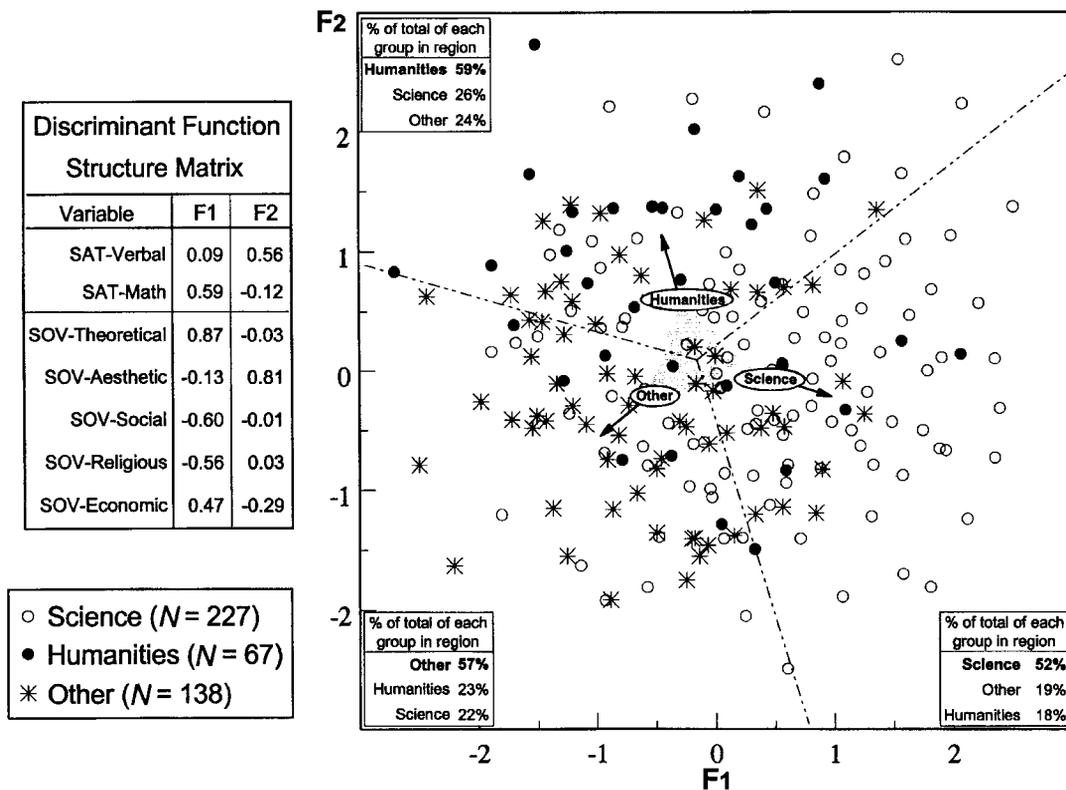

Figure 2. Discriminant Function Analysis

dent to optimally correspondent, a key component of our research is designed to uncover unique ways to enhance the learning experiences and intellectual development of the *exceptionally* able-to make it as optimally correspondent as possible. We suggest that Harriet Zuckerman's (1977) work provides clues for how to enhance educational correspondence among the exceptionally able, and this corresponds highly with what earlier writers have suggested (Seashore, 1922; Hollingworth, 1926, 1942). For this part of our thinking, we blend Zuckerman's hypothesis on the accumulation of advantage with Tannenbaum's (1983, 1986) work on the critical elements for world-class achievement. Considering exceptional achievement is important for purposes here, because it is this population that provides the intellectual leadership and role models for subsequent generations.

Zuckerman (1977) studied the career paths of Nobel Laureates and occupants of the 'forty-first chair' (scientists generally acknowledged to have done research of Nobel prize quality, but not awarded the prize). These individuals almost universally show promise extremely early in their careers and this evidenced precocity appears not only to respond to but also to create greater opportunities for intellectual development. For example, most Laureates receive an advantage in graduate work by attending the most distinguished universities (10 universities produced 55% of the laureates) and by studying with the best minds of the day—other Nobel Laureates or occupants of the 41st chair—thereby begetting a pattern of eminence's creating eminence. Zuckerman claims that the development of scientific taste, standards and self-confidence are the most beneficial results of the Laureate's apprenticeships (Stanley, 1992).

Moreover, future Nobel Laureates obtain degrees and start publishing earlier and more copiously than other scientists. Soon, by the quality of their scientific contributions, they become distinguished from their age-equivalent peers; this opens up further opportunities for their development. Zuckerman suggested that the descriptions of Nobel Laureates' careers fits well with the model of "the accumulation of advantage: the spiraling of augmented achievements and rewards for individuals and a system of stratification that is sharply graded" (p. 249). Moreover, almost all future Nobel Laureates were 'active' in creating this beneficial environment (Scarr & McCartney, 1983; Scarr, 1996; Bouchard, 1997).

Thus, among the gifted, it would seem that those who have the personal potentialities for manifesting exceptional achievement require special encounters with the appropriate environment to facilitate the emergence of world-class accomplishments (Lubinski et al., under review). Consistent with this view, Bloom (1985) noted from interviews of talented performers in a variety of disciplines that special experiences, sometimes interventions, are important for the develop-

ment of talent. Moreover, Tannenbaum (1983, 1986) postulated that great performance or productivity results from a rare blend of superior general intellect, distinctive special aptitudes, the right combination of non-intellectual traits, a challenging environment and the smile of good fortune at crucial periods of life. (The first three components seem to parallel the abilities and preferences discussed in the Theory of Work Adjustment and the latter two the work of Zuckerman.) According to Tannenbaum, success depends upon a combination of facilitators, whereas failure may result from even a single deficit. By virtue of its 'veto' power, then, every one of the five qualifiers is a necessary requisite of high achievement and none of them has sufficient strength to overcome inadequacies in the others.

The above discussion presents the scaffolding for our work on the dispositional determinants of contrasting educational/career paths of the gifted and, thus, leads to the conclusion that individuals who are ideally suited for careers in the physical sciences are gifted individuals with highly developed mathematical and spatial/mechanical reasoning abilities and intense investigative/theoretical preferences. It is these individuals who will *choose* careers in the physical sciences and engineering and remain committed to them. Gifted individuals with other ability and preference profiles will choose careers in other areas. Given this line of reasoning, to the extent that the sexes differ on specific abilities and preferences relevant to educational and career choice, disparate males/female ratios in certain academic and vocational domains will result. This will not only occur in math/science disciplines, but other disciplines as well; males would be expected to remain over-represented in some areas, whereas females would be anticipated to remain over-represented in others. Moreover, these differences should intensify at the higher educational levels; empirical evidence supporting these expectations is presented next.

### **Gender Differences in Abilities/Preferences: Their Implications According to TWA**

#### *Abilities*

Over the past two decades reports seem to indicate that certain gender differences in cognitive abilities are steadily diminishing in normative samples (Feingold, 1988; Hyde, Fennema & Lamon, 1990). That is, males and females appear to be converging toward a common mean on a variety of intellectual abilities. These trends, however, have not been noted among the most able (Stumpf & Stanley, 1998). Among the gifted, there are sizable gender differences at age 13, favoring males, in mathematical reasoning and in spatial and mechanical reasoning abilities (abilities required for engineering and the physical sciences). Moreover, at the end of high school and college, these differences remain and

accompany gender differences favoring males in maths/science achievement test scores (as well as other test scores), whereas females tend to do slightly better than males on a number of verbally oriented achievement tests (Stanley et al., 1992; Hedges & Nowell, 1995; Stumpf & Stanley, 1998). Before profiling these differences in some detail, we will first address the question: how can normative male/female means be converging while gender differences among the gifted remain pronounced? There are at least two possible explanations (and probably both operate to a degree): test construction practices and gender differences in ability dispersion.

First, Stanley et al. (1992) point out that it is difficult to assess group changes in performance on cognitive tests over the last few decades, inasmuch as a number of test publishers have routinely culled from their instruments items that characteristically generate the most conspicuous gender differences. This procedure is referred to by some as correcting for 'gender bias' or 'equity in testing'. Thus, it is possible that the apparent convergence of male/female group means is due to test construction practices as much as, or perhaps even more than, a genuine change in the cognitive attributes assessed by these measures.

Second, if meta-analytic reviews are indeed detecting a degree of genuine gender-convergence, consumers of meta-analytic reviews must keep in mind that this methodology provides information only on group differences in *overall level* of the attribute under analysis. Meta-analytic reviews do not provide information on group differences in other statistics such as those indexing ability dispersion. There are other parameters on which the genders can differ and a critically important one is *variability* (cf. Benbow, 1988).

Many lines of evidence suggest that males are more widely dispersed than females on a variety of intellectual variables. This phenomenon has been observed over several decades in normative samples (Lubinski & Humphreys, 1990a, 1990b; cf. Feingold, 1992; Lubinski & Benbow, 1992; Lubinski & Dawis, 1992; Hedges & Nowell, 1995; Halpern, 1997). Moreover, this phenomenon appears to hold even for variables on which females have superior means; an example of how this works might be helpful. Stanley et al. (1992) noted that the largest gender difference favoring females on the Differential Aptitude Test (DAT) is observed in DAT-Spelling. Grade 12 females score approximately 0.5 standard deviations above the males on this measure. Alternatively, one may state that only 30% of males score above the female mean; yet, because of greater male variability, male/female proportions are relatively uniform among students within the top 1% in 'spelling talent'. This finding and the general phenomenon of gender differences in ability dispersion has important implications for understanding male/female differences at exceptional levels of

achievement (Feingold, 1995). When assessing gender differences in achievement among the gifted, it is the upper tail of the ability distribution that is being examined; and this upper tail contains an inordinate number of males. Moreover, gender differences in dispersion and level often operate in concert to produce especially disparate male/female ratios at the extremes, as we will illustrate next by returning to SMPY's work with the mathematically talented.

In nationwide talent searches in the U.S., discussed previously, gifted students taking the College Board Scholastic Aptitude Test (SAT) have consistently generated the following pattern of scores. Gender differences in SAT-V are typically small. Yet, on SAT-M the difference between means approximates 0.4 standard deviations, favoring males, and males are more variable than females. Together, these differences in level and dispersion produce the following male/female ratios among 12- to 13-year-olds: SAT-M—500 (average score of college-bound 12th-grade males), 2:1, SAT-M—600 (83rd percentile of college-bound 12th-grade males), 4:1, and SAT-M—700 (95th percentile of college-bound 12th-grade males), 13:1 (Benbow & Stanley, 1983). Comparable ratios have been replicated across the U.S. in a number of talent searches across several years (Benbow & Stanley, 1996), as well as in other cultures. Score ranges beginning at SAT-M—500 are important for a 12-year-old to consider. They reflect important individual differences in quantitative sophistication (Benbow, 1992) and mark the level at which successful graduate work in engineering and the physical sciences at the very best universities becomes probable (Lubinski et al., under review).

The above gender difference in mathematical reasoning ability does not operate in isolation, however, to produce the profound gender disparities in educational attainment and pursuits along the maths/science pipeline. Gender differences in other abilities required by quantitatively demanding inorganic disciplines, especially spatial and mechanical reasoning, amplify the disparities. These abilities are frequently overlooked by investigators trying to come to grips with the underrepresentation of women in engineering and the physical sciences. Table 2 contains data that bear on this issue. They were collected on Cohort 4 by SMPY over a 6-year period (1992–1997). In addition to the SAT, students in Cohort 4 were administered a variety of non-verbal tests including Raven's Advanced Progressive Matrices, three-dimensional spatial visualization and mechanical reasoning. (A number of personal preference questionnaires were also administered, see below.) Gifted students at or above the cutting score for the top 1% in overall mathematical reasoning ability display trivial gender differences in not only SAT-V but also in Advanced Raven scores; yet significant gender differences were revealed for spatial ability and mechanical reasoning.

Table 2 also parallels the findings of Stanley et al. (1992). These investigators analyzed gender differences on the Differential Aptitude Test (DAT) in effect-size units, taken from a national sample of over 61,000 students. The most pronounced gender difference in this battery was observed in Grade 12 on the Mechanical Reasoning measure, the male-female effect-size difference was almost a full standard deviation (.89) favoring males. These gender differences in spatial and mechanical reasoning ability (Halpern, 1997; cf. Jensen, 1998), combined with the well-known gender differences in mathematical reasoning ability (Benbow, 1988), help explain why disparate male/female proportions are observed in inorganic scientific disciplines. Jensen (1998) has pointed out that in spite of these types of differences in specific abilities, there is a near-zero sex difference in overall general cognitive ability (*g*). This recalls Tannenbaum's assertion, discussed earlier, that success depends upon a combination of every one of his five qualifiers, two of which are general and specific abilities—and none of them has sufficient strength to overcome inadequacies in the others.

We conclude that because of sex differences in the configuration of specific abilities, the satisfactoriness criterion for engineering and physical science is less frequently met by gifted females compared to gifted males. This is only part of the picture, however. There are gender differences in *non-ability* personal attributes (vocational interests and values), in addition to life style preferences, that exacerbate disparities stemming from gender differences in satisfactoriness for the physical sciences. We turn to these next.

### Preferences

As noted earlier, physical scientists are characterized primarily by their high theoretical/investigative preferences (Humphreys et al., 1993; Humphreys & Lubinski, 1996; Achter et al., 1999) coupled with a *relatively* low need for people contact. Table 4 contains

some typical findings from talent search participants collected by SMPY during the 1990s. Both mathematically gifted males and females have, relative to their own sex norms, strong theoretical values and investigative interests. Yet, there are prominent gender differences in critical preferences for maintaining a commitment to careers in the math/science pipeline that mirror the aforementioned spatial/mechanical abilities among the gifted at age 13. Mathematically talented males are more theoretically oriented on the SOV (see Table 3). Further, their primary interests lie in the investigative and (secondarily) the realistic sectors of Holland's Hexagon (Achter et al., 1996; Schmidt et al., 1998). In contrast, mathematically talented females are more socially and aesthetically oriented and have interests that are more *evenly divided* among investigative, social and artistic pursuits (Achter et al., 1996; Schmidt et al., 1998). Females are more balanced and less narrowly focused in terms of their interests and values. (One could also say this about their abilities.) Consequently, the TWA satisfaction criterion is less often achieved for females than males when considering the physical sciences.

Thus, at age 13 more males than females possess ability and preference profiles that are congruent with choices to pursue highly focused careers necessary for distinction in the physical sciences. Due to their more evenly distributed preferences and abilities, the career choices of mathematically gifted females and the amount of time they devote to scientific careers will be less marked than their male counterparts. Males will be more exclusively committed to the sciences, while females will have competing interests and will tend to develop their talents in relatively equal proportions across artistic, social, and investigative educational/vocational domains (Achter et al., 1996). That is exactly what is found in our educational programs designed for adolescents in the top 1% in ability. Females enroll in courses in maths/science and English/foreign language in essentially equal proportions,

Table 2. Ability Profiles of Mathematically Gifted Students (Top 1%) Attending a Summer Academic Program (1992–1997) by Gender.

	N	Males $\bar{X}$	SD	N	Females $\bar{X}$	SD
Age-Adjusted SAT-M	238	519.5	82.9	141	517.0	72.6
Age-Adjusted SAT-V	226	434.7	90.0	137	445.3	82.8
Advanced Raven's	229	25.2	4.6	133	24.4	4.7
Mental Rotation Test	229	30.5	8.0	133	24.0	9.2
Mechanical Reasoning	229	50.9	6.9	133	44.6	6.3

Note: All SAT Scores are reported on the original scale. Any scores from the recentered scale have been converted back to the original scale using tables provided by the College Board. Scores from testers greater than the age of 160 months (13 years, 4 months) at the time of testing have been adjusted down by a factor of 5.4 points on the SAT-M and 4.6 points on the SAT-V per month for every month of age beyond 160.

Table 3. Interest and Values Profiles of Mathematically Gifted Students (Top 1%). Attending a Summer Academic Program Across Six-Years (1992–1997) by Gender.

whereas males were approximately six times more likely to enroll in maths/science areas than in English/foreign languages. TWA would predict that the same pattern will reveal itself when career choices, made at a later age, are examined. Indeed, this is the case.

This can be seen in the secured educational credentials that mathematically gifted students in Cohort 1 achieved (or were intending to achieve) 10 years following their identification at age 13 (Lubinski & Benbow, 1992): Less than 1% of the females in the top 1% of mathematical ability are pursuing doctorates in mathematics, engineering, or physical sciences (Lubinski & Benbow, 1992); eight times as many males are doing so. Benbow & Lubinski (1992) presented similar data just collected for SMPY's Cohorts 2 and 3. Finally, in our 20-year follow up of Cohorts 1 and 2 (Benbow et al. 2000), both males and females achieved uniformly high and commensurate numbers of advanced degrees. However, they did so in contrasting disciplines: males were more likely to choose engineering and the physical sciences, while females were more likely to choose the humanities, law, social science, and life science.

An alternative way to capture the essence of these gender-differentiating outcomes takes us back to Thorndike (1911) and one of the most celebrated dimensions of individual differences, "people vs. things." In normative samples, females tend to gravitate towards the former, while males gravitate towards the latter (cf., Lubinski & Humphreys, 1990a) and this parameter of individual differences operates among the gifted as well (Achter et al., 1996; Schmidt et al., 1998). Given the male-female comparability within medicine and the biological sciences, however, com-

pared to the physical sciences, perhaps it would be more precise to state that gender differences in vocational preferences and outcomes are structured around 'organic' vs. 'inorganic' content domains (Benbow et al., 2000; Lubinski et al., under review). It is not science, per se, that turns off many females but, rather, its inorganic nature (coupled with competing interests for other areas).

*Life-style choices.* Before leaving the domain of preferences, there is one critical gender difference in lifestyle preference that is essential to document (and one that is typically not assessed on standardized interest or values questionnaires). This gender difference is likely to exert a huge effect on gender differences even in disciplines in which male/female ratios in achieved educational credentials are comparable: commitment to full-time work as young adults. In our first three cohorts, for example, about 95% of mathematically talented males vs. less than 60% of such females plan to work full-time until retirement. This latter statistic would indicate that females, as a group, tend to devote less time to their vocational development relative to males. They tend to prefer a more balanced life. Females prefer to devote more time to family and avocational pursuits, relative to males. Further, in most research in this area, questions to respondents are typically framed in terms of full-time vs. various part-time options, not in terms of how much they are willing to work. Thus, we are currently assessing how the gifted feel about 50- to 70-hour work weeks, schedules more in line with people at the cutting edge of their discipline; this reveals further gender disparities. Males are much more likely than

females to be willing to work more than a 40-hour work week (Lubinski & Benbow, 2000, Figure 2, p. 143), whatever the reasons and their validity.

In sum, therefore, mathematically gifted females, in addition to having a more multifaceted interest profile and a more complex mixture of value orientations for evaluating their experiences and structuring their lifestyle, prefer to devote less time to vocational pursuits. They have more to balance, or more competing needs at comparable intensities. Mathematically gifted males, however, are more focused on a theoretical/investigative style of life with fewer competing pulls, and they prefer to devote a greater amount of time to vocational pursuits. Their lives are less balanced.

### Contemporary Research Trends: Viewed From the Context of TWA

We have illustrated above how the personal attributes of females compared to males will lead them to *choose* inorganic scientific careers less frequently, as a group, and to distribute their educational development across artistic, investigative, and social areas more evenly. Of course, conventionally purported barriers (Kerr, 1985; Silverman, 1986; Noble, 1989; Reis & Callahan, 1989; Eccles & Harold, 1992) might still remain. Our work does not address that issue. We suggest, however, that these and other purported barriers be evaluated from a broader context using TWA and its key components, satisfaction and satisfactoriness, to establish expectations on the degree to which comparable gender representation might be anticipated. According to TWA, because of their differing ability and preference profiles, highly able males and females achieve, as a group, satisfaction and satisfactoriness through different means. Consequently, they respond to the environment differently, as does the environment to them. Gender differences as a reflection of choice need to be factored into existing models and perceptions, and taken into consideration when thinking about how best to meet educational needs (Benbow & Lubinski, 1997). Failure to do so can result in inaccurate assumptions about 'multipotentiality' in the intellectually gifted (Achter et al., 1996), with less than cautious educational and vocational decisions leading to dissatisfaction and loss of productivity for males or females. Seeking equity in educational provisions by ignoring gender-associated patterns of choice will, paradoxically, result in *inequity* of educational opportunity (Benbow & Stanley, 1996). In contrast, considering each individual's unique constellation of talents and preferences (Lubinski, 1996, 2000) and the way these may interact to structure and direct adult intellectual development (Ackerman, 1996; Ackerman & Heggestad, 1997) bodes well for the possibility of excellence in achievement (Lubinski & Benbow, 2000).

Satisfactoriness and satisfaction baselines might also be useful for appraising theoretical explanations of gender differences in achievement more generally. For example, Eccles et al. (1983) introduced the expectancy-value model of motivation, which they proposed as a framework for understanding the relationship between values/personality attributes and academic achievement, as well as gender differences therein. This popular model describes two primary factors affecting achievement behavior: (1) expectations for success and failure, and (2) subjective task value. Moreover, it conceptualizes gender differences in achievement, just as we do, from a *choice* perspective rather than a *deficit* perspective. It also views choices as being made from a variety of options presented within a complex social reality, wherein gender roles and stereotypes operate (see Eccles & Harold, 1992, for a discussion of this model as it pertains to the gifted). Yet to what extent do expectations and subjective task value reflect realistic personal estimates of the degree to which TWA's correspondence dimensions, satisfactoriness and satisfaction, respectively, are achievable in contrasting educational and work environments? Is self-confidence and self-efficacy, for example, a reflection of the extent to which one is in a correspondent environmental ecology in the TWA sense?

Inadequate maths/science preparation is another factor often mentioned as curtailing women's career options. Sells (1980), for example, perceived mathematics in high school as a 'critical filter', screening out females from engineering and science majors. Indeed, the number of mathematics and science courses taken in high school is found to relate to choice of college major as well as career (Berryman, 1985; Ethington & Wolfe, 1986); gifted females, even mathematically gifted ones, do take somewhat less mathematics (and science) in high school compared to such males (Benbow & Stanley, 1982; Benbow & Minor, 1986). Consequently, it has been suggested that more females would enter and remain in the maths/science pipeline if they were required to take more mathematics and science courses in high school. But to what extent is course-taking among mathematically gifted females a reflection of their preferences and abilities? Preference and ability profiles are in place long before high school. Can they be changed appreciably as a function of course-taking? Would *requiring* mathematically gifted females with intense preferences for social and artistic content to take more mathematics, chemistry, physics, and computer science in high school increase their representation in the maths/science pipeline? Would *requiring* mathematically and spatially gifted boys with intense preferences for building and manipulating physical materials to take more high school courses in English increase their representation in the humanities? We do not have answers to these questions. To be clear, however, we are not arguing that

such course-taking is not beneficial in and of itself; we are certain that it would be. We simply do not know whether (or how much) it would change the direction of a student's development (e.g., see Holden, 2000; Kleinfeld, 1998–1999).

Some of the other factors thought to attenuate the professional development of women include those that women 'do to themselves'. These are, among others, the Queen Bee Syndrome (Staines, Tavis & Jayaratne, 1974), the Great Impostor Phenomenon (Machlowitz, 1982; Clance, 1985; Warschaw, 1985), the Cinderella Complex (Kerr, 1985) and the Perfection Complex (Reis, 1987). The Queen Bee and Perfection Complex are similar in that females feel that they have to be perfect in every way and in how they handle the multiple roles of professional, mother, and wife. The Great Impostor Phenomenon captures how many successful women feel they achieved their success-not through their hard work and ability but rather through luck: and they are waiting to be found out. To avoid being 'found out' they get caught in a circle of working even harder, achieving greater success and developing greater fear of being detected as the impostor they truly believe they are (Kerr, 1985, 1991). To what extent is this depiction characteristic of a gifted female with several competing interests at comparable intensities? These questions and others like them will be pursued in our future research. In all of our research, however, detailed assessments of well-known personal attributes critical for satisfaction and satisfactoriness in specialized careers and advanced educational tracks are conducted, not only to establish expectations for gender representation in the maths/science pipeline, but also the degree to which the self-perceptions of our students are reality based. Investigators in other areas of educational/vocational development, as well as theorists interested in indexing the magnitude of social psychological influences, might find this strategy profitable too.

### Conclusions

In this chapter, using TWA, we have organized data collected at SMPY with data of other investigators on key gender-differentiating attributes that channel the nature and degree of educational/vocational achievement among the gifted. We feel that this model is useful for conceptualizing and better understanding many different kinds of gender differences surrounding the manifestations of intellectual talent. We conclude with three points: one intended for researchers, another for theoreticians, and finally one for educators and applied psychologists. Although the expressed thoughts shared by these three categories possess appreciable overlap, they also reflect a unique emphasis.

First, for the researcher, if one thing is apparent from the last 30 years of research on the gifted and the gender differences therein, it is the need to conduct

multi-attribute assessments of key characteristics relevant to criterion behaviors of interest. Our particular area of interest involves the determinants of educational and career excellence in engineering and the physical sciences. It behooves us, therefore, to incorporate measures of spatial and mechanical reasoning into our correlational and experimental designs, in addition to assessing critical vocational interests and values and life-style preferences. We simply cannot restrict investigations solely to abilities, preferences, or attitudes (or any 'favorite' class of personal attributes) and expect findings to generalize with fidelity. There are simply too many gender differences observed in key variables relevant to multiple educational/vocational paths to make one-shot, one-variable designs unquestionably defensible.

Second, theoretical formulations must at least attempt to genuinely embrace all available evidence before casting highly integrative frameworks for interpreting research findings. Theorists certainly should not ignore relevant auxiliary data that speak to the tenability of certain conclusions. In another context, we have suggested that researchers employ the Total Evidence Rule for evaluating the verisimilitude of competing theoretical formulations. This rule of induction was formulated by Rudolph Carnap (1950). It maintains that consideration of all relevant information is essential when evaluating a proposed scientific assertion. There are multiple examples in the gifted literature for the relevance of this important rule, but the following two involving gender differences will suffice to illustrate its significance. First, if social influences are operating in isolation to attenuate the development of exceptional levels of mathematical reasoning abilities in females (as some have suggested), theorists must address why it is that females are superior to males in arithmetic computation and also tend to get better grades than males in high school math courses (cf. Benbow, 1988; Kimball, 1989). A second example involves sex-role identification. The masculine identification hypothesis has been used to explain the relative superiority of males compared to females in mathematical reasoning ability. This formulation must come to grips with the fact that regardless of how giftedness is defined (e.g. by selecting subjects based on exceptional levels of verbal, spatial, or mathematical ability), gifted adolescents of all 'types' are less gender stereotyped than their average-ability peers in a variety of interests (Lubinski & Humphreys, 1990a). Moreover, Lytton & Romney's (1991) meta-analytic review, covering the literature on parents' differential socialization practices as a function of their child's gender, uncovered many insignificant effect sizes for a number of abilities and social behaviors.

Finally, we, like most vocational psychologists working with young adults, feel it is important that gifted adolescents are provided with the opportunity to

develop in ways commensurate with their unique abilities and personal preferences (Lubinski & Benbow, 2000). If this means that more gifted females choose to become biologists, lawyers, and physicians, relative to physical scientists, electrical engineers, or computer scientists, as long as they are aware of their full potential we are not concerned. We view gifted students as individuals first, and try to be as responsive to their individual differences and uniqueness as possible. One can never be all that one has the potential to become, because life is too short and developing expertise requires much time. But people do possess wide variation for how readily expertise development is likely to take. As the great counseling psychologist, Leona Tyler (1992) noted: The important life decision is not what you can be as much as it is choosing what you would like to become from an array of possibilities. We only have one life to develop, and we don't have time to actualize all of our possibilities.

To paraphrase Maslow's, one must be responsive to one's true nature, a theme that cuts across many fulfillment theories and formulations aimed at construing optimal forms of human development and positive psychological states, including those of Gordon Allport, Carl Rogers & Carl Jung. It might be advisable for counselors and educators to keep such wisdom in mind when working with clients and students searching for direction in their educational and vocational development, and, perhaps also, to remind clients of Jane Loevinger's (1976) observation (contained in her treatment of ego development) that "personality develops by acquiring successive freedoms." All of this is actually encompassed by various models of educational and vocational development stemming from individual differences research (Dawis, 1992; Tyler, 1992; Williamson, 1965; Lubinski, 1996) and, in particular, TWA. TWA is an empirically based model of personal fulfillment within the world of work (Lofquist & Dawis, 1969, 1991; Dawis & Lofquist, 1984).

# Guiding Gifted Girls and Young Women

Barbara Kerr<sup>1</sup>

## Introduction

One of the most profound transformations in human society has taken place in the last three decades as women's roles have changed throughout the world. In the United States, girls have pulled even with boys in many ways. Eighth grade girls have caught up in maths achievement, belying hypotheses from a mere ten years ago that biological differences would preclude girls from the highest attainments in mathematics. Bright girls enroll in challenging biology, chemistry, and physics classes in almost the same numbers as bright boys. Strong efforts to help girls to raise their career aspirations, to attempt course work of greater rigor, and to claim leadership positions have been strikingly successful. As many young gifted women as gifted men now plan careers in medicine, law, and many other fields once dominated by males (Campbell & Clewell, 1999). About 80% of high school leadership positions are now held by girls, and girls' and women's athletics have captured the nation's imagination. Similar trends have been noted in England and Australia, as well as other developed nations.

## Changes in Girls' and Women's Roles

In industrialized countries, optimism about the gains that have been made by bright girls and women must be tempered by the fact that new problems have emerged. As girls and women become more assertive and enter leadership positions, they often take on the problems that have traditionally been the province of males: substance abuse, violence, and self-destructiveness (Phillips, 1998). In addition to these newly acquired difficulties, achieving girls and women are oppressed more than ever by societal images of the 'perfect' woman. Eating disorders are rampant as women try to achieve impossible ideals of physical beauty. Ninety per cent of people with eating disorders are women, and eating disorders have the highest mortality rate of any mental illness (National Institute of Mental Health, 1993). Finally, many of the gains that have been made in female achievement have been at the middle and high school level.

Gifted women in college and in young adulthood apparently still face both internal and external barriers to the attainment of their goals (Le Roux, 1994.) The gap in mathematics achievement test scores, particularly at the top range, have remained intractable, excluding gifted women from colleges and academic opportunities (Campbell & Clewell, 1999). College women encounter a virulent 'culture of romance' that forces them into competition for relationships with high prestige males (Holland & Eisenhart, 1990). Once in the workplace, bright women often face subtle forms of discrimination that prevent them from moving ahead. Young professional women face barriers not only in the workplace, but in their own homes, where the men they marry often do not support their ambitions or goals. As a result, gifted women continue to subvert their own dreams, compromising their goals and aspirations in an attempt to compose a lifestyle that will work for all the members of their families (Tomlinson-Keasey, 1999). Many of the conditions that make gifted women vulnerable to pressures to under-achieve as college students and adults begin to take effect in early childhood (Eccles, 1987).

In developing countries, there have also been striking changes in the condition of women that have directly affected the lives of gifted girls. In many countries where girls once received little or no education, the benefits of educating girls are becoming apparent; societies that educate their girls find that they marry later, have fewer children, contribute to the economic well being of their communities more than uneducated women. New efforts are being made to identify and nurture the talents of girls. However, girls' education still lags behind boys' education in much of the world, and worldwide, the economic and social status of women remains inferior to that of men. Bright women in many cultures still face forced marriage, prohibition from owning property, and legal and social support for emotional and physical abuse (Kitano & Perkins, 1996).

Therefore, the radical changes in women's roles in both the developed and developing countries have brought about some dramatic improvements in the

education and guidance of gifted girls in the last three decades; but much remains to be done to help bright females overcome the internal and external barriers to the achievement of their goals.

### Changes in the Construct of Intelligence

In addition to changes in the role of women, there have also been extraordinary changes in the ways in which psychologists, teachers, and counselors view the construct of intelligence (Morelock, 1996). Twenty years ago, the construct of general intelligence reigned supreme; it was an unquestioned premise of psychology that intelligence was a unitary phenomenon. Intelligence was considered so indivisible that school psychologists were cautioned to avoid at all costs the interpretation of separate scale scores for the WISC-R; so that verbal and spatial scores were always combined to create one intelligence score. There was indeed considerable data to support the notion of *g* or general intelligence: factor analyses of ability tests have inevitably shown an overall tendency for most of the major talents to cluster together (Anastasi, 1998). An advantage of this way of construing intelligence is that the tests devised to measure this set of general intellectual abilities have been good predictors of academic achievement. That is, intelligence tests have done a good job of identifying children who can benefit from increased academic challenge. Another advantage of this construction of intelligence is that the tests based on *g* were constructed to identify as many girls as boys and continue to identify girls equitably.

The major disadvantages of this construction of intelligence are the consistent failure of intelligence tests to identify children from cultures with world views that diverge from that of the test developers. Therefore, girls from non-competitive cultures as well as girls with limited English ability have not been able to display their superior reasoning abilities as well as white or Asian middle class children who have been brought up to value test-taking and academic achievement. Another disadvantage of this construction of intelligence is that children with specific extraordinary abilities in music and art—and even maths and linguistic areas are less likely to be labeled gifted. At the highest levels of performance, the concept of *g* breaks down: few child prodigies are gifted across domains of talent, and adolescents at the highest levels of achievement in specific talent areas are unlikely to be more than above average in other talent areas (Morelock & Feldman, 1993; Colangelo & Kerr, 1991). Therefore, it is conceivable that brilliant girl artists, musicians, mathematicians, and writers will be left out of gifted programming because they do not score brilliantly across the board.

Finally, although intelligence tests show asynchronous development fairly clearly, they are not reliable predictors of academic achievement until children are at least nine years old. However, precocious intellec-

tual behavior may be manifested in girls earlier than boys. If girls are not tested until nine because that is when the tests become useful for prediction of achievement, then many gifted girls whose cognitive complexity outstrips their social development may be missed (Silverman, 1995).

Gardner's (1983) theory of intelligence, which has led to many investigations of specific abilities and which has been enthusiastically embraced by many educators of the gifted, would seem to address many of the criticisms of the construct of general intelligence. His theory of seven intelligences does indeed account for the existence of both child prodigies in specific talent domains as well as for the evidence that specific abilities can exist in isolation in damaged brains. This theory is also useful in that it is much more inclusive; it brings many more young people into the 'gifted fold' who previously would have been left out. Because the theory is largely tested by the observation of achievement in talent domains rather than by paper and pencil or interview based testing, it can be argued that it provides a more practical and direct means of predicting future eminence in a talent domain. Proponents of this view of intelligence point out that eminent individuals are nearly always people with specific extraordinary talents, whereas many eminent people have only above average scores on tests of general intelligence (Gardner, 1993).

Silverman's perspective on this issue is that the newer theories of specific intelligences have clear gender biases. She says, "Current thinking in the field . . . from a masculine perspective—rejects IQ tests because the tests fail to predict who will win acclaim in specific domains in adult life. However, the tests do manage to locate approximately equal numbers of gifted girls and boys in early childhood . . . In fact, 47% (31) of the 66 children we have found above 180 I.Q. are female compared to less than 2% of the eminent! It is ironic that the very instrument that proved females to be equal or superior to males in intelligence is falling into disrepute. It has been replaced by a more vigorous emphasis on performance, achievement, and accomplishment in the new National Excellence report . . . the potential for eminence in another disguise—and educators are being warned not to 'label preschool and primary students as gifted and talented' despite the fact that gifted girls tend to go underground by the middle grades."

These changes, taken together, mean that our very definition of the gifted girl is in flux, as well as the attitudes of societies around the world toward the development of talent in women. Are gifted girls those who are asynchronous in their development, those whose overall intellect and capacity for perceiving the world seem to be developing out of pace with their age peers, or are gifted girls those whose talents combine with personality traits in such a way as to promote them toward eminence? Despite the suggested 'rap-

prochement' of the two models by Morelock (1996), research and theory on the education and guidance of girls has not reflected an integrative approach. The model of female talent development proposed by Noble, Subotnik & Arnold (1997) may hold hope for more synthetic understanding of giftedness in girls. This model, developed to provide an understanding of giftedness in women, takes into account intelligence, achievement, and distance from the center of power within the domains of human activities. In addition, it assumes that achievement and self-actualization are possible on many levels, ranging from personal to societal. In applying this model to girls, it may be possible to construct a means of identification of giftedness that assesses girls' innate abilities, their motivation and record of achievement, and the characteristics that put them closer or farther from the center of power in the dominant culture. In this model, a Navajo girl living on an isolated reservation who converses in both Navajo and English, who can read at the average level for urban white children, and who can perform at an average level on achievement tests normed on people with a world view entirely at odds with her own is gifted. The white, upper class suburban girl who scores in the 90th percentile on achievement tests and gets a B average may be less gifted than the tests say she is.

With regard to societal attitudes, we are in a time of ambivalence, when gifted girls are being urged to actualize their talents, particularly in maths and science, but discouraged at the same time from inconveniencing their families, communities, and society as a whole. The work of Kitano & Perkins (1996), Kitano (1998), Napier (1995), and Martinez-Thorne (1995) with international women, women of color, and indigenous women are illustrative of gifted females' struggle with societal ambivalence toward their giftedness. Kitano & Perkins (1996) found that the extraordinary achievement required extraordinary determination for international women. In many cases, women had initial support of their families for education only to learn that they are still expected to marry a man of their parents' choosing and to subjugate their goals to that of their husband. One of the women in Kitano's study told of escaping into education because her family wished to marry her to an old man she hated. Napier tells of Native American women leaders who struggled to maintain their cultural identities while participating in educational systems that could not recognize or understand their world view. Martinez-Thorne explains the pressure upon Hispanic American women scholars to remain loyal to traditional roles.

The research reviewed here reflects a diversity of perspectives on giftedness in girls, and suggests ways of providing guidance to girls and young women based on that diversity.

### **Gifted pre-school girls**

Gifted pre-school girls go unidentified for a number of reasons; one of the most common reasons is that parents are diffident about bringing in girls for testing. Research has shown for later grades that parents are less likely to enroll girls in special gifted programming than parents of boys, perhaps because they are more reluctant to challenge them (Silverman, 1986.) Generally, parents of girls tend to 'overhelp' them, protecting girls from the rigors of difficult problem solving. There is reason to believe that this phenomenon is at work in parents' resistance to testing gifted girls (Kerr, 1997). Second, many psychologists are unwilling to test pre-school girls, because of the unreliability of intelligence tests for predicting later achievement; there is also the possibility that they are less willing to challenge girls than to challenge boys. Third, there is considerable confusion among psychologists and educators about the meaning of precocious reading (Jackson & Kearney, 1999). Because it is well known among educators that precocious reading does not necessarily predict giftedness, many discount parent diagnoses of giftedness based on precocious reading. This, however, is a misunderstanding of the nature of the relationship of female giftedness to reading. Most gifted girls learn to read earlier than gifted boys, and are more advanced in their reading skills than gifted boys throughout school. Although not all precocious readers become intellectually gifted students, nearly all gifted students—particularly gifted female students—were precocious readers. Therefore, precocious reading in a girl should not be discounted as a developmental fluke, but should be investigated as a possible sign of giftedness.

Although sex role behavior is learned as early as three years old, gifted girls tend to be less rigid in their sex role identification than average girls (Terman & Oden, 1935; Kerr, 1997). They are likely to be more open to playing with both girls and boys, and are likely to enjoy adventurous, active play that is usually preferred by boys. They may play with toys in a more complex way, inventing new games with even the most passive feminine toys (doing surgery upon a Barbie or marrying her off to Lego robot). Pre-school gifted girls have vivid fantasy lives, and are more likely than average girls to have invisible playmates or imagined characters.

Jane Piirto's advice for the guidance of children with specific creative talents is relevant to gifted girls (1998), as are counseling strategies recommended by Kerr (1997) for girls with specific extraordinary abilities. Gifted girls of three and four can benefit from exposure to a second language. They are likely to learn both languages in a bilingual family very quickly. Fears about linguistic confusion, leading parents to speak in only one language, are probably unfounded. Second languages learned at this age tend to be learned with

near perfect accents, particularly by gifted girls, who seem to excel in language acquisition. Musical instruction should also begin at this age; recent studies show that musical instruction must begin by age 6 if a child is to have a 'natural' talent. Pitch, tonal memory, and rhythm memory may all be better learned at this very early age, since music is one of the earliest developing talents.

Mathematical precocity may appear in girls just before kindergarten as well, and because it is, like music, an early maturing ability, needs immediate challenge and guidance. Gifted girls tend to love counting games and early computational games, and computer programs that offer 'jump starts' are often very enjoyable to pre-school gifted girls. Social mathematics, like counting games, seem particularly appropriate for girls, who will throughout school prefer maths instruction that is linked to real life and to sociable activities. One of the most neglected areas of pre-school stimulation for girls is spatial-visual activities other than art. Because girls receive so little opportunity to play with Legos, construction toys, and other toys requiring mechanical and spatial manipulation, they may fall behind boys in spatial-visual skills. Therefore, spatial-visual challenge is particularly important, because later these skills will be needed for mathematics and effective use of technology.

Gifted girls who come to the attention of counselors and psychologists in the pre-school years are usually brought to professionals for testing when parents observe their unusual precocity and become concerned. Among upper middle class families who have not yet encountered the school system, there is often the belief that proper identification of their girl's giftedness will lead to better educational opportunities. This belief is often rapidly challenged by the unwillingness of educators to provide those opportunities.

One of the most frequent questions asked of guidance providers is whether to enroll gifted girls in school early. In most societies, early admission to schooling or early grade skipping were the tools of choice for accommodating gifted children's special abilities. In the early twentieth century, when Terman & Oden (1935) set out to identify gifted children, they found that an overwhelming number of the children identified by their teachers as gifted were the youngest or second youngest in the class. In contemporary United States and Australia, however, where a sort of radical egalitarianism holds sway, it is considered wrong to give bright children the special 'privilege' of early admission or grade skipping. In addition, in these societies, social adjustment is considered more important than intellectual challenge, and parents are discouraged from making a decision for early schooling. As a result, many parents are confused, and consult guidance providers about this decision.

Although of course every gifted girl is unique in her needs, and decisions must be made based on other

variables besides early reading or maths ability, there is both clinical and research evidence that early admission to schooling for gifted girls is a simple and effective way of providing for intellectual challenge (Silverman, 1986, 1993). Gifted girls usually read earlier than gifted boys, are less physically active, and better adjusted socially, so they are a better bet for early admission than gifted boys. If girls are moderately gifted, have good social skills and have already mastered reading, then early admission may be indicated. Parents of highly gifted girls need to be warned that early admission alone will probably not address their child's needs; highly gifted girls are likely to still be so asynchronous in their development that entry by just one year is not enough, and two or more years places them at risk for being bullied by much larger children. Small, ungraded classes emphasizing self-paced learning may be the best option for these girls.

### Primary age gifted girls

Across cultures, the early primary grades mark the time when the intellectual gifts of girls are most evident (Kerr, 1997). Most nations have compulsory schooling until at least fourth grade, so all over the world, girls at this age are afforded the opportunity to display their gifts. In addition, girls of this age have not yet internalized beliefs about female inferiority. As a result, most gifted girls are eager to show their superior reasoning and memory and happy to be asked to recite, draw, sing, play an instrument, or dance. They do their best because they have not yet learned the costs of being different from the other girls or superior to boys; they continue to behave like first class citizens. Gifted girls in primary grades outperform boys in all areas of academics, receiving higher grades and higher achievement test scores. In terms of psychological adjustment, primary age gifted girls are also superior to gifted boys and average girls and boys (Janos & Robinson, 1985) Even for highly gifted girls, ages five through nine are likely to be less troubling than later years, as long as they can find sufficient challenge for their abilities. Gifted girls at this age are filled with the excitement of learning, and usually reading, learning, and practicing skills take precedence over the pursuit of popularity.

Research confirms that gifted girls have higher grades than gifted boys throughout the school years. However, a disturbing pattern begins to emerge in fourth and fifth grade when gifted boys begin to receive higher achievement test scores in maths and science than gifted girls. It is the beginning of a gap between the achievement scores of the most highly gifted girls and boys that will continue throughout their lives, reducing the choices of gifted girls and women while opening doors for gifted boys and men. Sadker & Sadker (1994) have shown persuasively how achievement tests are biased against girls. Items on achievement tests reflect boys' experiences more than that of girls; items about sports, machinery, and

wagering are of little interest to girls. In addition, studies have shown that girls do less well on tests of speed; timed tests of maths are nearly always biased against the more reflective style of problem-solving that is characteristic of girls. All of the major achievement tests are not just tests of knowledge or reasoning ability; they are tests of speed and brashness, characteristics which may predict little about a girl's true capacity for learning. It should be noted that girls excel at the language sections of achievement tests. However, boys' inferiority in reading and language skills is seldom held up as a cause for major concern the way girl's lesser performance is in mathematics. Girls are assumed to be deficient in the area of maths and science, and the difference in scores at the highest level, although attributable to many causes, is often held up as proof of gifted girls' deficiencies.

Although girls in the late primary grades begin to fall somewhat behind the boys in achievement tests, they continue to outshine boys not only in grades but in overall adjustment and self-esteem. Gifted girls before age 11 are strikingly confident. They assert themselves in groups, and will argue for their opinions. They have high self-efficacy, believing they are good at many things, particularly school work. At both five years old and eight years old, they have strong self-concepts; they have high opinions of their physical self, their academic selves, and their social selves (AAUW, 1991; Brown & Gilligan, 1992).

Finally gifted girls have high career aspirations. Gifted girls' career aspirations since the time of Terman have been higher than those of average girls. In the last twenty years, gifted girls' aspirations have continued to climb; at this point their career goals are just as high as those of gifted boys (Gassen, Kelley & Feldhusen, 1993). The major difference between the aspirations of gifted girls and gifted boys are the stronger altruistic and social motivations behind the goals. Gifted girls nearly always want careers that make people's lives better, or that make the world more safer and more beautiful for its beings. Gifted girls are idealistic and optimistic about their potential to do good.

When gifted girls come to the attention of counselors and psychologists, it is seldom for conduct disorders, underachievement, or adjustment disorders. Gifted girls' good mental health and frequently observed resilience usually mitigates against the need for in-depth treatment (Czeschlik & Rost, 1994). It is more likely to be some extraordinary situational disturbance that brings gifted girls into therapy: the death of a parent, a very difficult divorce, or exposure to abuse are some of the few situations that gifted girls may not be able to adjust to without professional help. In addition, therapists who counsel gifted girls who have some other risk factor such as inherited depression, autism, or personality disorders may find these conditions complicated by giftedness. Some have even called

gifted children with this combination 'dual diagnosis' clients because of the complex ways in which giftedness interact with other disorders. Therefore, it is important that guidance providers recognize that when a bright girl is referred for counseling, her situation and condition may be very bad indeed.

In addition to gifted at-risk girls, another category of bright schoolgirls who may need professional help are the highly gifted girls. Leta Hollingworth noted the severe burdens that are placed upon girls of great genius to be 'normal', and showed several girls' valiant efforts to do so. However, gifted girls of over 150 IQ or in the 99+ percentile on measures of achievement may simply be too different to camouflage their true abilities. Upon showing these abilities, many gifted girls will be cruelly rejected by other girls and will find themselves isolated. Kaufmann (1981) found that many of the highly gifted Presidential Scholars in her study had been unrecognized as high achievers and labeled as loners as children. Therefore, guidance providers have a special responsibility for highly gifted girls. Highly gifted girls need a caring, listening adult who will not only help them to get the academic stimulation they crave, but who will understand their loneliness and isolation. These girls often need assurance that they will some day find peers with whom they can talk, and the counselor's help in making that possible. Referral to conferences and camps for highly gifted, as well as support groups may be one of the most powerful interventions. Hollingworth (1926) and Silverman (1993) have both noted that if highly gifted girls can find just a few friends of similar intellectual ability, they can have quite normal lives. This is perhaps one of the great beauties of the highly specialized chat rooms on the Internet; many of these allow highly gifted children from all over the world to converse with one another about their interests, both esoteric and common. Counselors who familiarize themselves with chat rooms and websites frequented by gifted children can do a great service by connecting their young clients with this great source of friendship and fun.

### Gifted adolescent girls

Once a topic spurned by feminists and non-feminists alike, the plight of the adolescent girl now is featured in the media everyday. The facts about girls' self-esteem plunge between 11 and 17; girls' loss of confidence in their own voices; and the high rates of eating disorders, substance abuse, and sexually transmitted diseases among teenage girls are fairly well known. However, many people believe that gifted girls are somehow protected by their intelligence. The vast majority of gifted girls continue to receive high grades and to have very high levels of involvement in extracurricular activities. However, there is evidence that they are also vulnerable to loss of self-esteem and to risky behaviors that can jeopardize their goals and dreams (Kerr & Kurpius, 1998).

Studies of the self-concept of gifted girls show a similar decline to that of average girls. Terman's girls actually declined in their performance on intelligence tests; administrators even speculated that they were no longer trying as hard. Groth's (1969) cross-sectional studies of gifted girls and women showed a sharp difference between the wishes of ten year olds and fourteen year olds, with ten year olds valuing the pursuit of achievements and the enhancement of their self esteem and fourteen year olds focusing almost entirely on desires for love and belonging. Groth commented that the fourteen year olds seemed to believe that achievement and love were mutually exclusive. Contemporary studies show the same transformation, as gifted girls "go into hiding." Gifted girls' concept of themselves slides in all dimensions—physical, academic, and social (Czeschlik & Rost, 1994).

How does the rapid change of fortunes in the psychological lives of gifted girls come about? The role of family, societal, and school expectations, achievement tests and grades, and girls' attitudes toward themselves have all been examined in an effort to understand what happens to adolescent gifted girls.

Gifted girls, particularly in traditional families and cultures, are expected to do an 'about-face' in adolescence (Reis & Callahan, 1996; Kerr, 1997); there is strong evidence that women who become eminent or achieving in Hispanic and Asian cultures are those who receive family encouragement that is out of the ordinary (Kitano, 1998). Up until puberty, intelligence in a girl is considered a positive characteristic, and little girls are encouraged in their school work and precocious behavior. However, with adolescence comes the expectation that the gifted girl will turn her attention to becoming an attractive potential mate. Few cultures perceive intelligence as an attractive characteristic in a woman; men tend to marry their equals or inferiors in ability (Kerr, 1997). As a result, most bright girls adjust to their culture's expectations of them. Girls all over the world tune in carefully to the media portrayals of women, and seek to emulate their television and musical stars in their makeup and dress. Gifted girls may focus their intelligence and creativity on diet schemes, shopping, and grooming rituals. In addition, gifted girls may become social experts, working their peer group in such a way as to increase their status and popularity with Machiavellian skill.

Portrayals of girls and women in academic materials are little improvement on media portrayals. Sadker & Sadker (1994) analyzed the content of commonly used maths, language, arts, and history books and found that girls and women were greatly underrepresented, with two to four times as many males depicted, and only 11 women's names mentioned in a popular 631 page history textbook. The items on tests and achievement tests, particularly in science and maths, feature problems that are more interesting to boys than to girls;

items about machines, wagering (If you had a poker hand that had two aces . . .), and sports tend to be of less interest to girls. Girls do less well on these items, but perform better on items with the same level of difficulty that pertain to issues of interest to them: nature and animals, arts and crafts, and people.

Adolescent gifted girls may also be at a disadvantage in the classroom because of teacher attitudes. Siegel & Reis (1995) found that teachers perceive their gifted girls as working harder and producing higher quality work than gifted boys, but still assign higher grades to the boys. Girls then seem to accept their teachers' judgments, and evaluate themselves as less able than the boys in mathematics and science. Cooley, Chauvin & Karnes (1984) found similar stereotyping, with teachers of gifted perceiving gifted boys as having superior critical thinking skills and problem solving abilities, and perceiving gifted girls as having superior creative writing abilities. It is interesting that although most teachers are opposed to sex role stereotyping, and while most make an effort to avoid stereotyping in general, they tend to see gifted boys as liking maths and being better at it than girls (Fennema, 1990).

According to Sadker & Sadker (1994), achievement test scores may be the biggest culprit in gifted girls' sudden slide in self esteem. Because the gap in maths and science achievement is largest at the highest levels of achievement, gifted girls are particularly aware of the differences in their scores from those of gifted boys. Despite the evidence they have from their high grades that they can have outstanding performance in maths and science, they seem to give achievement test scores more credence. As a result, many gifted girls lower their estimate of their abilities as well as lowering their self-esteem.

Talented at risk girls are particularly vulnerable to this process. Because most achievement tests do not provide accurate predictions of the academic abilities of Native American, African American, and Hispanic girls, these girls are often greatly dismayed by achievement test scores. These girls may have had consistently high grades, but low achievement test scores come as a blow; many very bright girls will insist that they are not gifted after receiving their scores (Kerr & Kurpius, 1999.)

Adolescent gifted girls seek counseling and are referred for counseling for a wide variety of reasons, although again, it must be stressed that the incidence of severe behavioral problems is much lower in gifted girls than in average or low ability girls (Janos & Robinson, 1985). At risk behaviors include bulimia and anorexia; drug and alcohol abuse; unsafe sex and unwanted pregnancy. In gifted girls, these behaviors take on different meanings than with the general population of girls (Kerr & Kurpius, 1999). Eating disorders are often an extension of adolescent gifted girls' high needs for achievement. When society demands a thin, attractive body as opposed to an

educated mind, these girls may attempt to become the thinnest girls in the school. Drug and alcohol abuse are compounded by gifted girls' ability to hide their problem behaviors, to create cover stories, and to distract adults with academic achievement. Even alcohol abuse can be a sort of achievement for the gifted girl who wants to prove her ability to binge with the boys. On the other hand, unsafe sex and unwanted pregnancies are sometimes the result of gifted girls wanting to prove their femininity; early sexual activity may mean acceptance into the social group by a girl who is otherwise an outsider.

The problems of being multipotential can also bring gifted girls into counseling. Multipotentiality of gifted students, first identified as a major problem of gifted students at the Wisconsin Guidance Laboratory for Superior Students (Sanborn, 1979) is the ability to select and develop any interest. These students have a wide variety of extracurricular activities, 'high flat' interest profiles showing them to be interested in almost every occupational category, and high grades across the board. For gifted girls, being multipotential often translates into excessive involvement in out of class activities and difficulty making decisions about colleges and career directions. Counselors may see girls who are physically exhausted from their rigorous schedule, and who have sudden long absences as a result of stress-related illnesses. In addition, gifted girls may agonize over college choices because of their inability to define a career interest.

The tendency of gifted young women to camouflage their abilities and to deny their giftedness is itself well hidden; that is, bright young women continue to receive very high grades and to perform well in the classroom while telling their friends that they are just lucky, or using other strategies to diminish their own accomplishments (Reis & Callahan, 1996). The slide in self-esteem is seldom evident to counselors. Therefore, only those counselors who carefully question girls about their abilities will be able to discern the inner barriers to achievement and actualization that are well developed by adolescence.

A great number of career development and counseling interventions are now available for adolescent gifted girls. A wide variety of National Science Foundation funded projects to encourage girls and young women in maths and science are now available for replication (NSF, 1999). Interventions specifically for gifted girls that have been developed include a counseling workshop to raise aspirations and overcome multipotentiality (Kerr & Erb, 1991); a workshop for raising self esteem and self-efficacy in maths and science as well as overcoming at-risk behaviors (Kerr & Kurpius, 1999); a method of attributional retraining to help gifted girls re-attribute difficulties with maths scores (Heller & Zeigler, 1996); and a diagnostic-prescriptive workshop to overcome internal and external barriers (Hollinger & Fleming, 1992).

Over 100 National Science Foundation experimental and model projects are aimed at increasing girls' and women's participation in maths and sciences. Projects range from in-school changes to Girl Scout projects. Although not specifically targeted for gifted girls, many of the projects created guidance interventions that are appropriate for gifted girls. The Girl Scout project, for example, links girls with mentors who are scientists in a wide variety of fields and allows them to engage in experiments that will eventually be presented or published. Another project fills classrooms with posters of women mathematicians and scientists, and shows how they attained their goals. Another coaches girls and young women on how to improve scores on maths and science portions of achievement tests. Therefore, many of the projects, by encouraging career development through mentoring, modeling, and coaching, are excellent models for the development of maths and science talent in gifted girls.

Kerr & Erb (1991) developed a counseling procedure that is effective in overcoming multipotentiality as well as developing a sense of identity and purpose. This counseling procedure involved individual assessment on vocational and personality tests; group counseling in which students visualized the future and set goals; and individual test interpretation and goal-setting. Students who experienced these workshops were more likely than controls to set higher goals, to change interests to those in keeping with their values, to increase their understanding of their personal identity, and to make career plans for future. Kerr & Robinson-Kurpius (1999) redesigned the counseling intervention for talented at risk girls, adding a group counseling intervention for overcoming at risk behaviors. They found that girls in the experimental group, the majority of whom were poor Native American, Hispanic, and African American girls, had increased self-esteem, increased maths-science efficacy, increased hope for the future, and decreased risky behaviors.

Heller & Ziegler (1996) used nine sessions of re-training, modeling, and feedback to teach gifted young women to attribute their successes in statistics to ability and effort and their failures to lack of effort or to the consensus that the problems were difficult for everybody. They were successful in retraining attributions to a great degree; the control group got worse, and the tendency to attribute failure to an internal, stable trait ("I'm stupid in maths") completely disappeared in the treatment group.

In Hollinger & Fleming's (1992) Project CHOICE (Creating Her Options in Career Education), counselors diagnosed barriers that stood in the way of gifted girls' achievement, and then prescribed strategies for overcoming those barriers. Gifted girls' self-esteem, achievement motivation, and attitudes toward success were assessed, as well as the support they received from family, peers, and schools. For each girl, a set of

barriers were identified, and a means of overcoming those barriers through mentoring programs, career education, counseling, and discussions with parents were developed. Follow-ups of students from five to fifteen years after the program showed that participants had benefitted greatly from the program. The majority had gone on to professional and other high level careers in their chosen areas, and had successfully combined marriage and family with rewarding work.

## Conclusion

There is reason for both optimism and concern about the condition of gifted girls and young women, and the guidance available to them. Internationally, the achievement of gifted girls is increasing, and the participation of gifted women in leadership roles in their societies is expanding. New methods of identifying and providing for the education of gifted girls are proliferating. Nevertheless, problems in identifying the talents of girls in societies where male talent development is the norm remain. Both the timing and the nature of the assessments of female giftedness need to be examined, so that early developing intelligences are nurtured. Efforts to operationalize the model of female talent development suggested by Noble, Subotnik, and Arnold need to be considered.

In addition, guidance remains necessary to help girls to survive pressures to subvert or camouflage their talents, to overcome at risk behaviors, and to learn ways of developing their career dreams and goals. Many promising methods of encouragement and guidance of gifted girls are being tested and implemented; these methods need to be disseminated and shaped to fit the cultures of girls throughout the world.

# Inclusive Education for Gifted Students with Disabilities

Carolyn Yewchuk<sup>1</sup> and Judy Lupart<sup>2</sup>

## Introduction

In our initial chapter (Yewchuk & Lupart, 1993), we presented a broad overview of many areas of study and practice associated with giftedness and disability. In the present chapter, we report on ensuing changes in the field reflected most predominantly in current educational settings throughout the world. The first change we have made is in our terminology. The term *gifted handicapped* has been changed to *gifted students with disabilities* to be consistent with contemporary usage which differentiates the qualities of the person from his or her disability. The initial chapter sections entitled *Definition, Incidence, and Identification* have been revised under one heading, *Gifted Students With Disabilities*, in the present chapter. This represents a general trend away from labeling and diagnosis to providing information that will be relevant and helpful to general classroom teachers who are the individuals most likely to bear responsibility for the learning and talent development of gifted students with disabilities.

Two previous sections, *Emotionally Disturbed Gifted* and *Preschool Handicapped Gifted*, have been deleted in the present chapter since there has been no relevant new information in these two areas, and two new topics, *Gifted Students with Attention Deficit/Hyperactivity Disorders* and *Gifted Students with Visual Impairment* have been added. The remaining topics have been revised and updated with particular attention to the move towards inclusive schooling. Finally, in light of recent general and special education reforms throughout the world, we have emphasized inclusive educational programming in our presentation of *Primary Subgroups of Gifted Students with Disabilities*.

## *Gifted Students with Disabilities: Still a Desultory Duality*

The growing momentum of the inclusive education movement in the last two decades has increased concern with providing appropriate education for all children in the mainstream classroom, including those with exceptional learning needs (Lupart, McKeough & Yewchuk, 1996; Booth & Ainscow, 1998; Friend, Bursuck & Hutchinson, 1998). During this same time period, there have also been tremendous gains in the relatively late-developing area of gifted education (Heller, Monks & Passow, 1993; Yewchuk, 1996). Unfortunately, the educational needs of certain subgroups of this population of children, gifted students with disabilities, have been slow to receive recognition (Lupart, 1992; Johnson, Karnes & Carr, 1997).

Interest in individuals with high potential and disability is not just a contemporary phenomenon. There are many historical examples of gifted men and women with handicapping conditions who have made significant contributions to society, for example, Thomas Edison, Helen Keller, and Franklin Roosevelt (Goertzel & Goertzel, 1962). Other notable persons, such as Albert Einstein, Woodrow Wilson, and Auguste Rodin had learning difficulties in reading, writing, and spelling (Thompson, 1971). Despite the widespread recognition of a few such individuals, we have no way of knowing how many more individuals with disabilities failed to develop areas of potential giftedness because of lack of recognition and support or inappropriate schooling. In the past, gifted children with disabilities were generally underserved. Where they received special educational services, it was in the area of disability without provision for their gifts and talents. Only those few individuals who had the support of informed, concerned families and/or visionary, innovative educators were able to develop their potential giftedness (Johnsen & Corn, 1989).

Since the 1970s there has been increased professional awareness of gifted students with disabilities as an underserved subpopulation of students (Whitmore, 1986; Gallagher, 1988). In the United States, the Association for the Gifted, a division of the Council for Exceptional Children, established a subcommittee of

educators of gifted children with handicaps. The first national conference on gifted and talented students with disabilities was held in 1976 and in 1977 the term 'gifted handicapped' was added to the Educational Resources Information Center indices (Porter, 1982). By the mid 1970s in the United States, at least eight special programs for gifted children with disabilities had been developed (Maker, 1977), and special interest groups advocating on behalf of these children had been created (Johnsen & Corn, 1989).

One notable example is Very Special Arts, an organization founded in 1974 to enrich the lives of children, youth, and adults with disabilities (Johnsen, Karnes & Carr, 1997). This affiliate of the John F. Kennedy Center for the Performing Arts sponsors non-competitive programs and festivals in drama, dance, music, literature, and the performing arts. It has since expanded to include international affiliates in over 83 countries around the world (see the VSA website at <http://www.vsarts.org>).

By the early 1980s, education of gifted children with disabilities was being hailed as a 'new frontier' (Whitmore, 1981), and educators were being challenged to develop procedures for identifying creative potential in these children (Ford & Ford, 1981), and to make appropriate use of new technology in the classroom (Higgins, 1981), while attending to areas of deficit (Karnes, Schwedel & Linnemeyer, 1982). Despite this early flurry of professional interest in gifted students with disabilities, leading American advocates noted a general neglect of the actual special educational needs of these students during the 1980s (Whitmore, 1989) and continuing on into the 1990s.

#### *Barriers to the Appropriate Education of Gifted Students with Disabilities*

Over the past two decades general education, special education, and gifted education have undergone tremendous reform (Fullan, 1991; Lupart, McKeough & Yewchuk, 1996; Yewchuk, 1996). Unfortunately, these reforms tend to be separately channeled through the dual systems of regular and special education (Lupart & Webber, 1996; Skrtic, 1996; Lupart, 1998). Paradoxically, reform efforts associated with special education have been mainly focused on equity issues, and reform efforts associated with general and gifted education have addressed excellence issues (Skrtic, 1996; Lupart, 1998). As a result, continued separation of regular and special education in contemporary schools may lead to a single outcome, either excellence or equity, not both (Skrtic, 1995).

Critiques and discussions by leading American advocates for gifted students with disabilities reflect the inconsistencies that arise out of dual systems of education (Whitmore, 1989). In one of Whitmore's interviews, Karnes noted that teachers of the gifted are usually unaware of handicap services, while teachers of children with handicaps are not trained to recognize

potential gifts or talents. In some instances, state consultants for gifted children may not even know their fellow consultants for children with disabilities (Whitmore, 1989).

From Gallagher's perspective, the neglect may be attributed to both administrative, logistical, and psychological barriers (Whitmore, 1989). The problem lies in allocating limited resources for special program development to the very small number of students who are both gifted and disabled, while psychologically, people who work with one group of students may not be able to respond appropriately to the other group. "Children who are gifted almost seem to be disliked . . . for their potential, or disregarded at the very least" by professionals trained to work with the handicapped, while educators of the gifted "can be made uncomfortable even by the presence of handicapped children in the same program" (Whitmore, 1989, p. 8-9).

To Hanninen, the emphasis within special education programs on the handicapping condition rather than on serving the whole child has contributed to neglect of potential giftedness (Whitmore, 1989). When the handicapping condition is very severe, teachers consider the development of basic skills so important that other considerations, including encouragement of gifts and talents, are relegated to a position of secondary importance.

Johnson, Karnes & Carr (1997) identify the following barriers hindering the identification and programming for gifted students with disabilities: (1) inappropriate identification procedures; (2) stereotypic attitudes; (3) lack of information about the nature and impact of developmental delays; (4) inadequate training of professionals; (5) lack of program models, research, and dissemination strategies; (6) lack of supportive technology; (7) lack of appropriate career counseling; and (8) inadequate funding.

In spite of the perceived neglect in educational provisions for gifted students with disabilities during the 1980s and 1990s, professional concern for this subpopulation of students has remained strong. Many reform leaders are now promoting a merged or unified system of educational provision for all students, in the belief that all children, particularly those with exceptional learning needs stand to reap significant, positive benefit (Goodlad & Lovitt, 1993; Skrtic, 1995, 1996; Lupart & Webber, 1996; Lupart, 1998).

#### *Future Promise in Inclusive Education*

Although educators are, in general, positive about the notion, there are wide variations in the ways inclusion is defined and practised in the schools (Bunch, Lupart & Brown, 1997; Booth & Ainscow, 1998). According to Andrews & Lupart (1999), inclusive education means that all children have the right to be educated in their community schools, and that general classroom teachers have the ultimate authority and responsibility for educating them. Emphasizing professional collabor-

oration that merges the best of regular and special education practice (Idol, 1996; Wong, 1996), and a belief in the simultaneous attainment of excellence and equity (Skrtic, 1996; Richert, 1997; Lupart, 1998), three enabling conditions for inclusive education are: (1) professional training and development; (2) pooling of material and professional resources; and (3) administrative leadership and support (Andrews & Lupart, 1999).

Moving toward truly inclusive education systems will not happen easily or overnight; however, the potential benefits for gifted students with disabilities are immediately obvious. First, an emphasis on the continuous progress of all students means that teachers are concerned about discovering and nurturing personal talents and learning abilities, rather than what category a child belongs to. Second, by eliminating a costly, time-consuming, and possibly elitist special education identification process, limited resources can be effectively deployed to support teachers in developing and implementing individually appropriate classroom programming adaptations. Third, expertise can be shared and extended for specialists and classroom teachers through collaborative consultation. Fourth, shared responsibility for all students fosters innovation and teaming in educator relationships. Fifth, a commitment to achieving both excellence and equity provides the challenge necessary for creating a true learning community.

Although inclusive education placements for children with multiple disabilities is widely supported (Fuchs & Fuchs, 1994), parents and professionals working with gifted children who learn best with specially trained teachers in segregated class settings are actively opposed to the inclusion movement. They are concerned that bright and talented children who flourish in special classes with their intellectual peers may again find themselves unchallenged in classes geared toward students of average ability (Yewchuk, 1996). There is strong support in many quarters for maintaining educational placements outside the inclusive classroom for those students who need it (Fuchs & Fuchs, 1994). The (American) National Association for Gifted Children (1992, back page) is on record as supporting grouping of students because it "allows for more appropriate, rapid, and advanced instruction, which matches the rapidly developing skills and capabilities of gifted students." With these possibilities in mind, we present a general overview of the contemporary field of gifted students with disabilities, followed by specific information relevant to general classroom teachers for each primary subgroup of gifted students with disabilities.

### Gifted Students With Disabilities

The incidence of gifted students with disabilities is low compared to other segments of the school population. Estimates range from a conservative 2% of all students

with disabilities in the United States, or between 120,000 and 180,000 (Schnur & Stefanich, 1979) to a more liberal 5% or between 300,000 and 540,000 (Whitmore & Maker, 1985). Data from studies of specific subpopulations of gifted students with disabilities have varied even more. Mauser (1980) found 2.3% of students with learning disabilities to be gifted. Karnes and Johnson (1986) reported that 9.2% of preschool children with disabilities met their criteria of giftedness. Among students with hearing impairment, the reported rates are 4.2% (Gamble, 1985) and 6.1% (Yewchuk & Bibby, 1989a). Approximately 2 to 5% of school-aged children with visual impairment are considered gifted (Ferrell, 1994). Neither the estimates nor the empirically derived percentages can be considered definitive because of the range in criteria for giftedness and the nature, severity, and effect of disabilities.

Gifted students with disabilities require special education services for one or more areas of potential giftedness, and one or more types of disability. These students form an extremely heterogeneous group, with great variability in profiles of strengths and weaknesses.

Students with disabilities include those who require special education services for mental retardation, hearing impairment, speech impairment, visual impairment, serious emotional disturbance, specific learning disability, or orthopedic or other health impairment, either singly or in combination (Individuals with Disabilities Education Act, 1997). Special education services are indicated if the disability prevents children from performing appropriately in regular school programs.

Definitions of giftedness based on multiple criteria of high potential are more amenable to the identification of gifts and talents in children with disability than the more stringent traditional definitions based only on extremely high intelligence. The definition proposed by Marland (1972) and subsequent amendments by the U.S. Congress (1978, 1988) that included not only high intellectual ability but also high performance capability in specific academic areas, the arts, leadership, and creativity have influenced broadening the concept of giftedness to include children with disabilities. A student with disabilities, like any other student, can meet the criteria for giftedness by showing high potential and/or performance in at least one of the specified areas, irrespective of average or even deficient performance in other areas.

The characteristics of giftedness which students with disabilities exhibit (Whitmore, 1981; Pledge, 1982; Udall, 1985; Whitmore & Maker, 1985; Yewchuk & Bibby, 1989a) are similar to those reported for nondisabled students (Davis & Rimm, 1998), such as:

- Superior memory and general knowledge
- Superior analytical and creative problem solving skills

- Notable drive to know, or master
- Superior use of language, oral or written
- Exceptional comprehension
- Keen sense of humor
- Persistence in pursuit of academic or intellectual tasks
- Awareness and/or ability to capitalize on personal strengths.

Furthermore, successful gifted students with disabilities have been observed to have an intense drive to succeed in reaching their goals and the capability of devising creative coping strategies for goal attainment. These have been shown to include strategies for overcoming personal limitations (Whitmore & Maker, 1985), and alternate solutions to attainment of a goal (Robertson, 1985). Gifted individuals with disabilities, in general, have a positive vision of their potential, accurate self-knowledge of their strengths, and a high degree of energy in trying to reach their goals (Whitmore & Maker, 1985; Wingenbach, 1985).

Some of the positive qualities of gifted students with disabilities, however, may not appear praiseworthy to adults around them (Friedrichs, 1990). For instance, these students might aspire to negative goals, such as identifying and criticizing inconsistent school policies (Rosner & Seymour, 1983). They may also exhibit negative characteristics associated with having a disability (Meisgeier, Meisgeier & Werblo, 1978; Whitmore & Maker, 1985; Nielsen & Mortorff-Albert, 1989; Vespi & Yewchuk, 1992):

- Struggles with self-acceptance
- Fragile self-concept
- Feelings of social discomfort, embarrassment, shame
- Intense frustration and anger
- A need to release or vent pent-up energies
- Interpersonal difficulties with peers, teachers, and family
- Academic difficulties in selected skill areas.

For some gifted students with disabilities, the interaction between positive and negative characteristics may develop into emotional/behavioral difficulties (Schiff, Kaufman & Kaufman, 1981), social isolation through withdrawn or aggressive behaviors (Meisgeier, Meisgeier & Werblo, 1978), suicidal tendencies (Yewchuk & Jobagy, 1992), avoidance of academic and social involvement because of a powerful fear of failure or rejection (Vespi & Yewchuk, 1992), psychologically painful school experiences (Reis, Neu & McGuire, 1997), external locus of control, field dependence, poor achievement motivation, and learned helplessness (Bireley, 1991). Where gifted students with disabilities are treated as handicapped to the neglect of their intellectual ability, a 'handicapped' or dependent pattern of behavior is likely to emerge. However, a

supportive, facilitative environment can foster the emergence of a 'gifted' pattern geared toward success in academic endeavors and social interactions with peers (Bireley, 1991). Special educational interventions in supportive settings are crucial if gifted students with disabilities are to come to terms with the discrepancy between expectations based on self-perception of high abilities and low achievement resulting from the disabilities (Vespi & Yewchuk, 1992).

Because disabilities can mask intellectual ability, talent, and creativity (Maker & Grossi, 1985), gifted students with disabilities are not as likely as non-disabled gifted students to be identified as gifted for special school programming (Davis & Rimm, 1998). Disabilities can disguise a child's true potential and abilities, and impede the expression of characteristics revealing giftedness (Maker, 1976, Gerken, 1979). Identifying the true ability of a child with handicaps who cannot speak or hold a pencil, for example, presents a unique challenge to educators (Minner, Prater, Bloodworth & Walker, 1987; Minner, 1990).

The key to recognition of giftedness in students with disabilities lies in adequately trained special educators, gifted educators, and mainstream educators (Johnson, Karnes & Carr, 1997). Classroom teachers require special training to identify giftedness in students with learning disabilities (Minner, 1990). Gifted educators require familiarization with disabling conditions and their effects on learning. Until teachers received inservicing on the characteristics and educational needs of gifted students with disabilities, Eisenberg & Epstein (1981) did not receive a single nomination for their gifted program from teachers of 60,000 students with handicaps in New York City. In Minnesota, concerted state efforts to ensure that all student groups were represented in gifted programs yielded positive results: 77% of special education program coordinators and 81% of gifted education coordinators reported that gifted students with disabilities were being served in gifted programs (Grimm, 1998).

The following practices are conducive to identification of gifts and talents in students with disabilities:

- Be familiar with the characteristics of giftedness and talent, and how they can be manifested by students with handicapping conditions. Create situations where students with handicaps have the opportunity to display gifted and talented behavior.
- Ideally, an examiner who is similarly disabled should be involved in the testing process (Stefanich & Schnur, 1979).
- The norm group for a student with disabilities should include a subgroup of peers with similar disabilities who have experienced a similar degree of developmental delay in language development and intellectual functioning through lack of access to information, opportunity, and resources (Maker, 1977).

- Standardized tests of intelligence and achievement developed specifically for subpopulations of students with handicaps, such as the Hiskey Nebraska Test of Learning Aptitude (Hiskey, 1966) for deaf children, or the Perkins-Binet for blind children (Warren, 1984) should be used. Where such instruments are not available, checklists and tests should be examined and assessed for appropriateness of use, bearing in mind the unique characteristics of the particular subgroup (Corn, 1986; Johnson, 1987). Another suggestion is to consider a cut-off of 120 or 125 on any one of the Verbal, Performance, or Full Scales of the Wechsler instead of the more conventional 130+ for identifying gifted students with learning disabilities (Schiff, Kaufman & Kaufman, 1981; Fox, 1983; Udall & Maker, 1983; Yewchuk, 1986).
- Tests should be modified only if the examiner is thoroughly familiar with the limitations imposed by specific types of disability and the special concessions appropriate for that type of disability (Pendarvis & Grossi, 1980). Ways in which students compensate for a disabling condition, and characteristics instrumental in successful adaptation should be given special emphasis. If normal channels of expression are inaccessible, tasks requiring problem solving, memory, critical thinking, and creativity might be appropriate (Whitmore, 1981; LaFrance, 1995).
- Multiple sources of information, including standardized tests (achievement, ability, aptitude), teacher and parent referral, and student observation, maximize the likelihood of identification and facilitate a balanced, holistic view of the child's abilities (Lupart, 1990; Grimm, 1998).
- Special educators should have course work in gifted education, gifted educators should have course work addressing disability issues, and classroom teachers need familiarity with both fields to recognize the needs of gifted students with disabilities in inclusionary settings (Karnes & Johnson, 1991; Johnson, Karnes & Carr, 1997). Provision of appropriate educational programming for gifted students with disabilities is facilitated when teachers, psychologists, counselors, parents, and others can work together to provide services for children with special needs in the inclusive classroom.

### Primary Subgroups of Gifted Students with Disabilities

#### *Gifted Students with Learning Disabilities*

Unlike other groups of gifted students with special needs, who can be identified by some type of discrete loss such as visual impairment, children with learning disabilities do not constitute an easily identifiable group (Brody & Mills, 1997). Learning disabilities may take many forms and involve some or all of the abilities inherent in using spoken or written language

and mathematics. Disorders in basic psychological processes underlying oral expression, listening comprehension, written expression, basic reading skills, reading comprehension, mathematics calculation, and mathematics reasoning are presumed to arise from central nervous system dysfunction (Individuals with Disabilities Education Act, 1997).

Many gifted students with learning disabilities appear intelligent and excel in one or more areas, but they have major difficulties in other areas. There may even be great variability in performance within a subject area such as reading (McGuire & Yewchuk, 1995, 1996). These students are often identified incidentally as a result of assessment for other purposes (Fox, 1983; Brody & Mills, 1997). Utilizing advanced abilities to compensate for the learning difficulties (Weill, 1987), they may function at or near grade level, and the teacher may not be aware of their gifted potential (Gunderson, Maesch & Rees, 1987). Some are initially referred for assessment of learning difficulties, and found to have IQs in the gifted range. Still others are referred for psychological assessment because of personal and social problems and subsequently found to be gifted (Schiff, Kaufman & Kaufman, 1981).

Surveys of special education and gifted programs in Texas have shown that gifted students with learning disabilities often fall into the gap between the two types of programs (Boodoo, Bradley, Frontera, Pitts & Wright, 1989; Tallent-Runnels & Sigler, 1995). Students receiving special education services for a learning disability may not have the opportunity to exhibit superior abilities, because of the remedial emphasis of such programs. Teachers who have training in special education, however, are more likely to identify gifted students with learning disabilities than regular classroom teachers without such training (Waldron, Saphire & Rosenbaum, 1987). Screening checklists can alert regular classroom teachers to the characteristics of these students (Dix & Schafer, 1996).

Many parents of children with learning disabilities in special class placements are apprehensive about the merging of regular education and special education. It took 30 years of lobbying to get recognition of, and instructional provision for, their children's learning needs in special classes (Learning Disability Association of Canada, 1993), and they are concerned about potential loss of these gains. Indiscriminate full-time inclusive placement of all children with learning disabilities would not meet the needs of those children who require intensive and continual instruction from specialists trained in learning disabilities.

Given the multiplicity of possible combinations of areas of giftedness and learning disability, comprehensive assessment aimed at developing an individual program plan should follow initial screening. The assessment should include both a summary profile of

the student's intelligence, achievement, creativity, self-concept, teacher evaluation, and family support. This information can be derived from interviews with teachers, parents, and counselors; the student's cumulative record, and additional testing as required; and a structured individual interview focusing on the student's self-perception as a learner, approach to academic tasks, organization of work, and work habits (Lupart, 1990).

The individual program plan derived from the assessment should include strategies for enrichment of gifts and talents, strategies for remediation of and compensation for deficits, and strategies for enhancing personal development (Yewchuk, 1992). Individualized programs developed in accordance with Kaplan's (1986) Differentiated Curriculum Model (Hishinuma, 1991; Clements, Lundell & Hishinuma, 1994) and Renzulli's (1977) Enrichment Triad Model (Baum, 1984, 1988, 1994; Baum & Kirschenbaum, 1984; Baum & Owen, 1988; Baum, Emerick, Herman & Nixon, 1989; Olenchak, 1995) extend, challenge, and stimulate creative productivity in areas of strength, encourage development and use of alternate modes of thinking and communicating, and foster critical thinking and research skills in independent project activities. Remedial activities directed at areas of deficiency are addressed in the context of the enrichment activities, and compensatory techniques for bypassing areas of difficulty are encouraged. Involvement of parents in monitoring and reinforcing homework and afterschool activities can result in improved academic performance and classroom behaviors (Sah & Borland, 1989). In addition to differentiated and/or individual programming in the regular classroom, gifted students with learning disabilities may require individual or group counseling of social and emotional needs, such as a powerful fear of failure resulting from the conflict of high expectations and low achievement in academic subjects (Vespi & Yewchuk, 1992); feelings of frustration, resentment and anger directed at themselves, their parents, their peers and their teachers (Mendaglio, 1993); low self-concept (Hishinuma, 1993; Olenchak, 1994); and willful repression of negative school experiences (Reis, Neu & McGuire, 1997).

#### *Gifted Students with Attention-Deficit/Hyperactivity Disorders*

Attention-deficit/hyperactivity disorders (AD/HD) are characterized by symptoms of inattention, hyperactivity, and/or impulsivity that are developmentally inappropriate and not the result of other conditions (Turnbull, et al., 1999). These disorders fall into three subtypes.

The inattentive type is characterized by day-dreaming, distractibility, forgetfulness, apathy, underachievement, social withdrawal and/or difficulty paying attention in class. In contrast, the hyperactive-impulsive type includes students who are restless,

talkative, fidgety, rebellious and/or impulsive. In the third, combined type, students manifest characteristics of both inattention and hyperactivity-impulsivity (Turnbull, et al., 1999; Kaufmann & Castellanos, Chapter 6, Part V, of this Handbook).

Many gifted students are mistakenly diagnosed as having AD/HD, while others are not appropriately identified (Delisle, 1995; Silverman, 1998). Since many of the behaviors associated with AD/HD may be exhibited by high-energy, high-intensity gifted students and highly creative students without actually having the disorder, distinguishing between the two conditions is not easy. Close examination of the environmental, curricular and contextual factors associated with the problematic behaviors is required (Webb & Latimer, 1993; Lind & Silverman, 1994; Delisle, 1995; Reid & McGuire, 1995). It is important to distinguish between the two conditions because the educational treatment is different (Lind & Silverman, 1994).

Children with AD/HD exhibit the behaviors in all settings, to a greater or lesser degree, while for gifted children problem behaviors are situation specific, e.g. lack of challenge. With the possible exception of television and computer games, children with AD/HD have short attention spans, in contrast to gifted students who can focus on tasks of interest for long periods of time. In general, children with AD/HD are inconsistent in the quality of their performance, unlike gifted students who, providing they are intellectually challenged, maintain consistent efforts and high standards.

Gifted students with AD/HD are characterized by asynchrony between advanced intellectual/academic abilities and immature social skills or emotional reactions, which may be poorly tolerated, even by gifted peers. They may have increased intensity and emotional reactivity to environmental stimuli, and heightened intellectual and imaginative excitation (Lovecky, 1994). Strengths of gifted students with AD/HD include ability to work quickly and produce work of significant quality, a spontaneous and joyful approach to life, and a sweet temperament and trust of people (Lovecky, 1994).

Successful educational interventions for gifted students with AD/HD address both conditions on an individualized basis (Wolfe & French, 1990; Hartley, 1993; Lind & Silverman, 1994; Reid & McGuire, 1995; Ramirez-Smith, 1997). Suggestions for changing disruptive classroom behaviors include use of behavior management techniques, social modeling and self-monitoring techniques, and providing a structured environment. The curriculum must be differentiated to challenge and stimulate. Instructional strategies modified to accommodate gifted students with AD/HD are detailed in Kaufmann & Castellanos, Chapter 6, Part V, of this Handbook.

A controversial recommendation for treatment of AD/HD concerns the prescription of stimulant drugs such as Ritalin, which, in children, can produce a

calming effect and a focusing of attention. Between 70% and 80% of children with AD/HD respond positively to Ritalin (Pancheri & Prater, 1999). But it also has numerous possible side effects such as loss of appetite, insomnia, tics, headaches, and stomachaches (Pancheri & Prater, 1999). Medication should be used as a last resort, only after behavior management and instructional interventions have proved ineffective (Howell, Evans & Gardiner, 1997).

### *Gifted Students with Hearing Impairment*

The historical pattern for educating students with hearing impairment has involved placement in special programs based on disability rather than giftedness. In segregated settings such as schools for the deaf or special classes for hearing impairment, emphasis has been placed on development of language and speech, and opportunities for exploring areas of creative and intellectual potential have been minimal. Students with hearing impairment have been less likely to be identified as gifted than their hearing counterparts (Yewchuk & Bibby, 1989a, b; Vialle & Paterson, 1996). Nevertheless, many in the deaf community and some professionals working with deaf students believe that deafness has its own culture and language that can only be taught effectively in segregated classes and schools for the deaf (Commission on the Education of the Deaf, 1988; Fuchs & Fuchs, 1994).

The basic referral, assessment, and selection procedures used with gifted children, may be applied to hearing-impaired populations (Whitmore & Maker, 1985), in segregated or inclusive settings, with appropriate concessions to handicapping effects of hearing impairment (Pendarvis & Grossi, 1980), and the pervasive influence of deafness as a cultural difference (Vialle & Paterson, 1996). Verbal test scores should be given less prominence than non-verbal and performance scores (Rittenhouse & Blough, 1995). Intelligence tests should be individually administered and non-verbal in nature (Sattler, 1992). Functioning at or somewhat above grade level on standardized achievement tests may be indicative of giftedness (Yewchuk, Bibby & Fraser, 1989). Referrals by both teachers and parents should be part of the identification process (Yewchuk & Bibby, 1989a).

Suggestions for designing and implementing programming to meet the learning needs of gifted students with hearing impairment include the following (Maker, 1981; Pollard & Howze, 1981; MacDonald & Yewchuk, 1994; Rittenhouse & Blough, 1995):

- Programs should be flexible in both design and use to allow latitude in investigation of complex issues.
- Programs should emphasize the use of advanced reasoning and analytical skills over memorization.
- Programs should be individualized to match student interests, learning styles, and exceptional skills.

- Programs should include thematic units with alternatives for stretching and extending exceptional gifts and talents of students.
- Programming should include special education services for areas in need of remediation.

A school-based model consistent with these general guidelines was developed at the Texas School for the Deaf (Pollard & Howze, 1981). At the elementary level, two gifted resource teachers worked with the regular classroom teacher to enrich the curriculum. In the middle school, the gifted students were placed together for instruction in core subjects but integrated with other students for elective classes. Teachers of the core subjects were provided with inservice regarding gifted education, and had access to the services of a gifted education specialist. In high school, gifted students attended regular classes, as well as a special class for gifted students where they worked individually with a gifted education specialist.

### *Gifted Students with Visual Impairments*

Like students with hearing impairments, students with visual impairments have been educated historically in residential schools with other similarly affected students. Accompanying the trend towards placement of students into regular classrooms is an increasing awareness of the unique needs of those students who also have special gifts and talents (Ferrell, 1994).

Gifted students with visual impairment meet the criteria of giftedness and visual impairment. Visual impairment includes low vision (ability to read large print, with or without magnification), functional blindness (sufficient vision to move through environment, but braille required for reading and writing), and total blindness (Turnbull et al., 1999). Approximately one of every thousand children of school age have visual impairment, and of these 2 to 3% are gifted (Ferrell, 1994).

Giftedness is not as readily apparent in students with visual impairment as in the normal population because of the barriers to assessing true potential (Corn, 1986, 1992; Hackney, 1986). A teacher of students with visual impairment makes referrals for in-depth intellectual assessment upon evidence of only three of the characteristics usually associated with giftedness (Johnson, 1987).

Special problems arise when a student with visual impairment is placed with sighted students. Paskewicz (1986) found the major stumbling block to be the lack of adequate brailled materials and the waiting time for brailling of additional materials, which severely limits the depth and spontaneity of exploration of subject matter. Instruction in braille usage, orientation and mobility, socialization skills, and independent living must continue as part of the individual program plan

(Corn, 1986, 1992; Hackney, 1986). Successful placement in inclusive classrooms involves collaboration between regular classroom teachers, special educators, specialists in visual impairment, professional support personnel, parents, and the students themselves (Ingraham, Daugherty & Gorrafa, 1995; Lichtenstein, 1997).

### *Gifted Students with Intellectual Disabilities*

This must be the most paradoxical of all dually labeled children. How can an individual be unable to manage independent living, while simultaneously being capable of remarkable mental feats in other areas of endeavour? Such is the puzzle of the individuals referred to as 'savants'. Savants constitute an estimated 0.06% of all institutionalized retarded individuals (Hill, 1977) and 9.8% of institutionalized patients with early infantile autism (Rimland, 1978). Their areas of brilliance are judged not against others with similar disability, but against those of the normal population. Some savants, such as Yoshihiko Yamamoto, the "Van Gogh of Japan," have become famous for their creative productions (Morishima, 1974).

The extraordinary abilities of idiots savants are manifested in a number of discrete ways categorized by Hill (1974) and Rimland (1978). Best known categories include calendar calculating, artistic ability, musical ability, memorization of obscure facts, mathematical abilities, mechanical ability, and pseudo-verbal ability. Savants may excel in more than one area.

In most documented cases, the specialized skills of savants have developed in unsupportive environments without specific training (Yewchuk, 1999). In some instances, systematic interventions combining opportunities for developing specific areas of talent with counseling and individualized programming to develop social and life skills have produced dramatic results (Donnelly & Altman, 1994). Morishima & Brown (1977) document how, under the tutelage of special education teachers, a student with severe mental retardation developed sufficient observational, graphic, and artistic skills to become a renowned Japanese illustrator of insects. Individualized programs that address areas of deficit and islands of excellence hold promise for meeting the exceptional educational needs of savants. Their special talents can be fostered and developed within inclusive classrooms that emphasize continuous progress and development of all students, irrespective of general intellectual ability.

### **Conclusion**

Important changes have been taking place over the past decade in regular education, gifted education, and special education that will eventually have a significant positive effect on the education and full development of the learning potential of gifted students with disabilities. The adoption of a simultaneous commitment toward excellence and equity in our schools holds

promise for all participants within the learning community. Inclusive education offers the context for this to happen in general classrooms throughout the world, and eventually should figure strongly in helping to eliminate many of the limitations and barriers created out of separate, dual systems of regular and general education.

General guidelines for successful inclusion of gifted students with disabilities into regular classrooms, drawn from Cline and Schwartz (1999), Federico, Herrold & Venn (1999), and Turnbull, et al. (1999) include the following:

- The entire school, from the principal to the school custodian, needs to be committed to inclusive education. Teachers cannot do it alone.
- Collaboration among everyone involved in the educational process (students, families, teachers, paraprofessionals, special service providers, school staff, administrators, agencies, community members) is vital.
- Psychological and counselling services to students with and without disabilities, their parents, and teachers is important in establishing comfort and commitment to the inclusive education process.
- Staff development and training, material resources, physical resources, and human resources to support disabling conditions should be readily available.
- The appropriateness of inclusion for gifted students with disability must be decided on a case-by-case basis. Some children might be better served in segregated settings.

Even though much of our current knowledge base and classroom practice in educating gifted students with disabilities is still best depicted as a 'desultory duality', the future is decidedly brighter with a growing confluence of interests, practices, and visions in the education of all students from regular and special education. Though the review of the literature reveals apprehension about inclusive education among some parents and professionals working with children with special needs, and a somewhat disconnected and unmethodical knowledge base, progress in understanding the challenges and benefits associated with the blending of programs and services to best meet the unique needs of those identified is becoming more apparent. Certainly there have been impressive gains in both research and educational practice; unfortunately there are still only small pockets of this exemplary work being carried out.

The ultimate merging of general and special education into a unified educational system will hopefully generate schools that can provide an appropriate education for all students, including gifted students with disabilities. Indeed, successful efforts in this area might contribute significantly to the general reform, if not transformation of education in the future.

# National/Provincial Gifted Education Policies: Present State, Future Possibilities

Rose A. Rudnitski<sup>1</sup>

## Introduction

This is a sequel to the chapter on policy in the first edition of the *Handbook of Research on Giftedness and Talent*, 'National/State Policies Regarding the Education of the Gifted', written by A. Harry Passow, to whose memory this study is dedicated. That chapter focused on the policies of developed countries primarily situated in the Northern Hemisphere. Though this focus made sense because the policies and public educational systems of these countries are mature, this update takes a different perspective by presenting a critical analysis of gifted educational policy, comparing the gifted education policies of nations at different stages of development, delineating issues involved in designing national policies, and making recommendations. My intention is to be more inclusive and to highlight and critique the dominance of the conceptions and models used in developed countries as well as to raise questions about the assumptions upon which gifted educational policies are founded and their appropriateness, in their current construct, for all countries.

## Educational Policy

All educational policy decisions are political acts. They are made primarily to resolve tensions created by competing interests in any society. These tensions generally emanate from the desire for a high standard of living, making education a potentially high-stakes policy area, for we know that educational attainment correlates highly with development and material success (OECD, 1997). Restricting access to high levels of educational attainment has the effect of restricting access to economic success, and there are some groups in every society who believe that policies should reinforce these restrictions as they maintain the social order.

Other points of view on education that may create tensions that policies must attempt to resolve are the

view of some that education is a human right, while others view it primarily as an investment in economic development. There is friction between the view of education as having a general/academic purpose and those who view it as training in specific areas and skills. How important are the arts to a society? Are they important enough to merit the allocation of significant resources for the development of talented individuals, resources significant enough to limit those allocated for academics? These are the conflicts that are created when society tries to define what a general education entails.

There are major tensions created between the view that public education should support basic literacy and numeracy for all citizens and restrict access to post-basic education and training only to those who manifest potential spontaneously at the appropriate stage in life, and the view that advanced education for many enhances economic and social development for all (Hallak, 1990). No educational policy totally resolves these tensions. Some argue that gifted education policies sometimes exacerbate conflict and competition, not only within the borders of one nation, but also between nations. This is done through the basic assumptions on which gifted education policies are based, its 'fundamental canons', and on the assumptions inherent in defining giftedness as it is expressed in virtually every governmental policy that mentions it.

Passow (1993) defined policy as a plan that provides guidelines for action. He states, "A fundamental canon of a policy in support of gifted education is that there are children who, because they have manifested potential for outstanding achievement in a socially valuable area, require differentiated educational experiences adequate and appropriate to their special needs" (p. 29). The basic principle behind this canon is a sound one because gifted children do require educational experiences appropriate to their special needs, but the same argument can be made for all children. The fundamental canon of gifted education that makes so much sense when one is considering only the needs

---

<sup>1</sup> State University of New York at New Paltz, USA.  
E-mail: rudnitsr@matrix.newpaltz.edu

of the gifted, loses its cogency when the needs of all children are taken into consideration. Educational policy makers must consider the needs of all children, and resource allocations in education are inadequate to ensure an adequate education for every child. Unless an educational policy ensures that the special educational needs of every child can be met through some sort of personalization or individualization, then a policy that ensures that for only some children appears to be exclusionary to all the others. This is a common problem in many countries that have gifted educational policies (Passow, 1993).

Another problem with the logic of the fundamental canon is that many of the other children vying for the same resources, given the adequate or enriched educational experiences that those resources can provide, might manifest the potential for outstanding achievement. The goal of a gifted education policy could be broadened to expand exponentially as the policy succeeds in nurturing heretofore hidden gifts in some children. Most current policies aim to nourish the development only of those who manifest their gifts spontaneously with little nurturance and support. Can educational policy dare to expand the possibility for the development of talent in broader segments of the population? The purpose of the policy for the education of gifted students is a key factor in determining its effect on the students and on the society. Is success for gifted students enough in our global society?

Conceptions of what is gifted are also problematic. Gifted education was born on the cusp of the nineteenth and twentieth centuries, when the mental measurement movement dominated the conceptual and research paradigms in education and the social and behavioral sciences (Tannenbaum, 1983). Policy for gifted and talented students did not begin to develop to any extent until after the Marland Report (1971) was released in the United States and that country enacted legislation to encourage the development of state policies for the education of the gifted (Passow & Rudnitski, 1993). Some countries in Western Europe quickly followed suit (Passow, 1993). Now, on the cusp of the twenty-first century, conceptions of giftedness have broadened and are no longer very easily measured as the IQ was when the field was in its youth. This complicates the policy development process and the nature of policy at its core. What is socially valuable, the aspect that determines the meaning of giftedness, at one time in a society may not, in another age or under another political system, be as highly valued. What is socially valued varies from culture to culture, so even if it were possible to have homogeneous societies, the definitions of giftedness would have to be fluid to change over time. Who determines what is valued in a multicultural society? Should this determination always be made by a dominant culture in a Darwinian context of competition and domination and survival of the mightiest? Should the intent of gifted education

policy in an increasingly interconnected global culture be to mitigate the vicissitudes of the constant struggle for dominance by fostering cooperation and compromise through the integration of many conceptions of what might be socially valuable in determining definitions of giftedness? Perhaps it is time to take a critical view of our current national and state policies in the light of the needs of our fast-changing global society, keeping what is appropriate and changing for the future.

### Research Method

This study builds on the chapter in the first edition of this work (Passow, 1993), and on the author and her colleague's previous policy analyses (Passow & Rudnitski, 1993, 1994). It is based on an extensive review of the literature on educational policy, specifically targeting policies on the gifted, and on a survey of the gifted policies of several countries, developed and developing, Western and Non-Western, Northern and Southern. In the fall of 1998, faxes were sent to the ministries of education of 40 nations. Fifteen ministries responded to the initial inquiry by sending either letters explaining their policies or lack of them, or by sending the policy, itself. Additional policy information was gathered through Internet databases such as *Eurydice*. Though extensive data were gathered from this survey, general themes and trends will be summarized for this chapter, which focuses not so much on what each country does, but on the fact that the notions of what services are needed for gifted children and how they should be educated have not changed much in the latter part of the twentieth century. Recommendations for changes and the development of policies that are more likely to be congruent with the needs of a global society are presented at the end of the chapter.

### Findings/Trends

Though most countries reported having no policy to specifically deal with gifted or highly able students, the countries that did ( $N=8$ ) had several things in common.

- Their policies, even when they stated that they wanted to avoid fixed definitions of giftedness and talent, defined the gifted population in terms of intelligence and/or performance in formalized school settings. Performance almost invariably was assumed to be performance on tests, national, regional, or school-based. When appropriate to the discipline (e.g. art or music) performance was more traditionally defined as performance within the specific discipline.
- The services and accommodations for the gifted were ones that are normally provided locally, such as acceleration to tertiary education, summer programs, academic competitions and Olympiads, special classes within schools, and special schools. The most predominant services such as acceleration and pull

out enrichment have been characterized as more popular with educators because they are low cost and less threatening than separate services, which are expensive and construed as taking away resources from other children (Freeman, 1992).

- The policies of European countries and their former colonies had striking similarities because the educational systems of the former colonies were still based on the colonizing country's model. These first three bullets were characteristics of the Traditional model, which reflects the traditions of Western civilization in terms of its definition of education and its definition of giftedness.
- The policies of former colonies that diverge from the Traditional model, though the difference is slight, have educational systems that are built on their own distinct national culture. This is true of the United States, Australia and New Zealand, which have some of the most mature policies regarding the education of gifted students. The policies of these countries also have a focus on providing opportunities for a diversity of students to partake of services for the gifted. This is an aspect that is unique to these countries, but is one that is espoused in general education policies in developing countries that exhibit a commitment to equalizing educational opportunity across groups. In this chapter, these are called 'Talent Development' model policies. These policy models, though in need of more development, demonstrate the most promise for fulfilling the need to integrate multiple conceptions of socially valuable talents and abilities. Their intent is to be inclusive rather than to filter and narrow the field, though they are constrained by formidable remnants of strongly held conceptual foundations in the field and by the overwhelmingly widespread low priority given to the education of all children in every country. Every country, no matter what its education policy, allocates a relatively small amount of resources for education in comparison to resources allocated for military and other governmental functions (OECD, 1997).

### Discussion of Policy Content and Trends

#### *Present State: Identification and Filtering Processes*

The policy of Hungary is an example of the prevalent Traditional model of gifted educational policy. Students move through a system in which primary and early secondary education are compulsory, then they must qualify for further free education through performance on tests or in auditions and exhibitions, when appropriate. Some students thus identified early are placed in special schools that are connected to universities, which 'collect' them and place them on an accelerated track for tertiary education. Others are encouraged to participate in competitions and attend special classes. This model has worked for a long time

and is effective. However, a drawback that will emerge in the coming century as the world becomes a more global society economically, politically and socially, is that this model is most effective in more culturally homogeneous societies.

With a global marketplace, people are not only interacting more electronically, they are travelling more and farther than ever before in history, crossing borders not only for commerce, but to live. Almost all member countries of UNESCO acknowledged at its recent World Conference on Higher Education that providing higher education for a more diverse student population within their borders is a growing concern for the 21st century (Miller, 1999). This, coupled with a trend toward more global mobility in general, will pose many of the same issues that countries such as the U.S., Australia, and New Zealand face today in formulating educational policy—providing services that do not reflect cultural biases against indigenous and minority cultures and in favor of the dominant culture in resource allocation and human resource development. Traditional model countries would be well served if they looked to the policies of these three, which are currently paving the way toward more variability in options and definitions to prepare more citizens for citizenship and work in the knowledge-based global economy as well as to identify and serve the gifted.

#### *Future Possibility: Traditional Program Options with New Funding Sources*

None of the policies that were analyzed for this study diverged very much from the normal services that are offered to gifted and talented students, e.g. acceleration, special schools, etc. The United Kingdom outlined a new initiative for what the minister of education called *specialist schools*. Schools that apply for status as specialist schools receive funding to provide 'master classes' in specific areas in maths, science, technology, languages, sports and the performing arts. The ministry has assembled a national group of expert advisors to provide the philosophical foundations for the program, including definitions and identification procedures, and technical assistance to the schools. The most extraordinary aspect of this program is that it is privately funded. The government has collected more than 30 million pounds for the project from private sources so far. This raises the question of governmental funding for programs for the gifted, a core function of policy.

Hallak (1990) points out that governments are entrusted with the role of equalizer, simply because they distribute the public good. He contends that to fulfill the role of equalizer, "the State is required to finance education and training services for those unable to purchase them on the private market" (1990, p.78). Education is 'quasi public' because it can be provided either publicly or privately, at least by those who can

afford it. It is the responsibility of governmental policy to not only provide access to education for those who cannot afford it at all, but also to provide funding for those who cannot pay for the total cost of their instruction. This would require governments to fund all types of education, both formal and informal, at all levels, which is admittedly impossible. With limited resources, all governments must set priorities in their educational policies, and these are always reflected in the financial aspects of the policy. The new initiative in the UK is a first step in a new direction because it represents governmental use of private funds for education of a specific population, and the funds are not provided by the parents of the students to educate their own. These are private funds distributed through a governmental program to benefit the public. This epitomizes a new trend in educational policy that should be noted and followed, where appropriate.

Examples of the Traditional model of education policy being adopted by former colonies can be found in Asia, Africa and Latin America (Passow, 1993). The system of formal schooling with high stakes examinations determining the future path of the student's education is prevalent on all continents—a vestige of the lingering influence of colonization that possibly creates inappropriate models for the very students the policies are attempting to serve. Some countries have taken steps to formulate their own unique models.

#### *Present State: Some Problems with the Traditional Model*

A Latin American country where the traditional model has not helped to adequately serve the needs of the gifted or to equalize educational opportunity enough to have a positive, widespread impact on economic and social development is Brazil, where many of the common pitfalls of the traditional model are evidenced. Yet it also has examples of good program and policy elements that can be replicated elsewhere. An example of an equalizing program is the summer enrichment program for disadvantaged gifted students in Minas Gerais. This program is like a summer camp, where children live on a farm and do projects and hands-on problem solving activities that stimulate their interests and abilities. The small group attention and the setting make this an expensive endeavor, so the program is in financial trouble (Alencar, 1994). This is typical of many special programs for the gifted in countries where there are Traditional models of gifted education policy and generally traditional models of schooling for all children. It also typifies countries where the national economy cannot sustain adequate educational services for all children and where education is not the highest political priority.

The pitfalls of the policy manifested in Brazil are summarized in the following list and are characteristic of the pitfalls of the traditional model, especially for developing countries, which are usually former colo-

nies with few economic resources and reserves, and multicultural populations with indigenous populations with special needs caused by a history of oppression.

- Adoption of the Marland Report (1971) definition of giftedness or a variation on that definition with the accompanying assumption that only a small percentage of students, the upper end of the Bell Curve, will meet the criteria:

Gifted and talented children are those capable of high performance and/or high potential ability in any of the following areas, singly or in combination:

- (1) General intellectual ability
- (2) Specific academic aptitude
- (3) Creative or productive thinking
- (4) Leadership ability
- (5) Visual and performing arts
- (6) Psychomotor ability.

It can be assumed that utilization of these criteria for identification of the gifted and talented will encompass a minimum of 3 to 5% of the school population (p. IX).

- Over-reliance on American or other experts from developed countries with predominantly Western cultures as consultants in the development of the national policy for gifted education.
- Inadequate allocation of resources for education in general, with even less for gifted students.
- Tension between goals of equity and excellence manifested in attitudes toward the gifted such as expectations of perfection, over-identification of already privileged students from upper and middle classes, assumptions that giftedness is rare and that the gifted are a homogeneous population with many common traits (Alencar, 1994).

The adoption of the definition published in the Marland Report across the United States and much of the world in the 1970s and 80s can now be viewed from a historical perspective. It was a major step forward for the field. The leadership of the United States in "pushing the envelope" throughout the twentieth century cannot be denied in terms of policy, definitions, curriculum, and programming. The Marland Report provided a reasonably broad and very official definition that governments and legislative bodies could use with the confidence that it had credibility. It was a catalyst that started a chain reaction of policy development. That was a giant step forward. In the intervening years, the field has opened to include more theories of giftedness than the IQ (e.g. Gardner, 1983; Sternberg, 1988; Gagne, 1995). Program models have been replicated across the globe and a few new ones have been developed, though U.S. models continue to dominate. Clearly, the culture and economic system of the United States dominate the rest of the globe. It is time now to ask whether this domination is necessary

or appropriate in the area of educational policy, especially for the gifted. The adoption of a definition of giftedness from another culture communicates what is socially valuable in that culture. Though the adopting culture may share some of that value, surely every culture has its own socially valuable talents and skills that must be included in its definition of giftedness in order for its policy to be culturally appropriate. If this is not considered when adopting a definition, the adoption becomes an imposition.

One of the effects of calling in the most prominent experts in the field is the perpetuation of the dominance of developed countries. Developed countries produce the most experts, and developing countries look to them for guidance. This guidance usually takes the form of transmission of the ideas and values of the culture from which the expert hails. The similarities between the policies of most of the countries is probably due to this transmission. Now that some policies are in place and others are beginning to be developed, we must ask if this is one of the effects that we desired as a global field. Do we want the policy of every country to be similar? What purpose does this serve?

Most educational policies will continue to be ineffective until educators around the world unite and act as advocates for the children of the world. Is this not one of the commitments of educators of the gifted? When education is one of the highest priorities of every nation and it receives resources that are consistent with that high priority, there will be enough money to provide adequate services to meet the special education needs of gifted students and all students.

Gifted education policies with the goal of equalizing educational opportunity can be designed. Equalizing policies are more appropriate for developing countries where there are high rates of illiteracy and many children do not have the opportunity to attend school or access to a free education.

#### *Future Possibility: Expanding Program Models and Definitions*

An example of a country that has attempted to formulate its own unique model is Nigeria, where, in the 1980s, a magnet school approach was designed to accommodate the needs of talented students (Kolo, 1996). In this model, students exhibiting a propensity, talent, or disposition for a subject or area of human endeavor, choose a school based on that area and learn all subjects through themes that are related to the area of strength and focus. This is more in keeping with the talent development model adopted in the United States after the *National Excellence* report (Callahan & Hiatt, 1998). This model takes into account the fact that giftedness is not fixed and that talent enables students to provide the focused attention necessary to persevere and practice enough to develop talents, propensities and dispositions into gifts. Much of the policy in the

U.S., Australia and New Zealand that is focused at groups that are underrepresented in gifted programs uses the talent development model rather than the gifted programming model that prevails in more Traditional type frameworks, which were reflected in the policies of these three countries until very recently. The Javits legislation and the funding that accompanied it to develop models for identifying and serving diverse populations of gifted children helped to spur research and development and to redirect the field. This is a good example for developing countries to follow when development of educational policy for the gifted is initiated. A relatively small amount of funding to a large national pool of researchers to develop processes and models for specific regional, ethnic, economic and racial populations can make a big difference in the direction that policy takes.

#### **Future Possibilities**

An aspect of the Talent Development policies for gifted education is that they acknowledge that heretofore prevailing constructs of giftedness and what Miller (1999) calls educational merit have been strongly affected by economic and social privilege. Because of this, groups have been disenfranchised from access to identification as being gifted and therefore to programs and services. If one takes either the view that equalizing educational opportunity is necessary for economic development or what has traditionally been the opposing view that education is a human right, the obligation to equalize access to appropriate services for all students, including the disadvantaged, is central to the mission of governmental policy. For this reason, national and state policies for gifted education that neglect the obligation to equalize access to and opportunity for appropriate services are inappropriate for the 21st century. The talent development model should be the major push in the policy area in this field in every nation. Traditional models, unless they are designed with the purpose of exponentially expanding the population of gifted students through providing educational contexts and opportunities that elicit high levels of performance, simply serve to re-privilege the already advantaged students in a society. Policies should be designed to newly-privilege the marginalized.

In a recent international study using educational researchers from nine nations in four geopolitical regions, using Delphi techniques and trend extrapolations, Parker, Ninomiya & Cogan (1999) found that the most significant challenges that the world is thought to face in this century include:

- The widening economic gap between the wealthy and the poor within countries;
- The inequalities between those who have access to information technologies and those who do not and the increasing disparity between them;

- Increasing conflicts of interest between developing and developed nations (Parker, Ninomiya & Cogan, 1999).

The authors suggest that, to meet these challenges, students must have educational experiences that develop their:

- Ability to look at and approach problems as a member of a global society.
- Ability to work with others in a cooperative way and to take responsibility for one's roles/duties within society.
- Ability to understand, accept, appreciate, and tolerate cultural differences.
- Capacity to think in a critical and systematic way.
- Willingness to resolve conflict in a non-violent manner.
- Willingness and ability to participate in politics at local, national, and international levels.
- Willingness to change one's lifestyle and consumption habits to protect the environment.
- Ability to be sensitive toward and to defend human rights (e.g. rights of women, ethnic minorities) (p. 125).

Can the field of gifted education meet these challenges with its current policies? Will our students, as a result of the education that we provide them, be prepared to take the leadership positions that we assume they will take in order to help the world meet these global challenges? Or will our education simply prepare them to get good jobs and make more money? Do we want to complacently design policies that maintain the ever-growing global inequalities that result in an ever-increasing waste of human potential? Or do we want to solve the problem of the widening wealth and opportunity gap? Policy is a political plan of action. It is a societal commitment to move in a direction. It is time for new policy directions in gifted education, locally, nationally, and internationally that reflect our commitment to a peaceful, cooperative, global society.

It is moral and wise for developed countries to begin the process of viewing policy as a means of equalizing educational opportunity internationally. Though there is no world government, there is a worldwide network of educators and researchers in gifted education. There are also many global, international corporations that are willing to fund initiatives that promote world peace and prosperity. A statement from the gifted field on equalizing educational opportunity and access to gifted services and talent development opportunities would be a major innovation and contribution to the future. It has historically been the place of this field to be the first field of experimentation in pedagogic and curricular practices. Policy innovations should also be our purview. Using private funds to formulate a statement and an experimental program that is less rooted in Western constructs and that acknowledges cultural

differences such as those outlined by Stevenson (1998) and Sternberg (1997) as well as disparities in privilege would be in keeping with current trends and meet global needs for the future.

### Conclusion

Policies on educating gifted students worldwide are generally traditional in their definitions of giftedness and models of providing accommodations for those students in school settings. These settings are defined in formal, traditional ways in those policies, thus cementing the foundations of these policies in the early 20th century constructs of intelligence and schooling. New models that reflect the needs of a global, information society and economy are needed. Talent development models and international models are the first step toward meeting the needs of the 21st century.

# Changing Paradigms for Gifted Education in the United States

James J. Gallagher<sup>1</sup>

## Introduction

The end of one century and the beginning of another is an ideal time to reflect, and look forward, to consider where the United States is going in this field of education of gifted children. The new millennium provides us a chance to ask old questions and to see if we have some new answers bolstered by experience and research. Some of the questions concern gifted children and youth themselves. How are they different from the average child? How can one find them? What should we be doing to enhance their capabilities?

Then there is the cultural context in which the gifted child is growing up. Is the child growing up in a one-parent home in poverty able to show his/her capabilities as well as the child of two professionally educated parents who can provide many advantages to aid the development of their child?

What about the educational context? What themes and theories are driving the educational enterprise and what effect is that having on the stimulation of gifted children? We are aware of a continuing struggle between *equity* and *excellence*, two important American values, for the scarce resources available to educational programs. The beginning of the twenty-first century is a good time to review all of these broad issues and chart a course for a rapidly changing future.

We have become accustomed to using a variety of paradigms or models as a way of organizing this complex field. We have had one paradigm for *intelligence*, another for our *public education system*, and still another for how we should educate *students high in intelligence*. All of these models or paradigms have been under challenge in recent times with many persons demanding change. If we are going to move forward into the twenty-first century we need to

reexamine these guiding paradigms to see how they fit our current knowledge.

## The Paradigm of Intelligence

One of the major changes that have taken place in the past few decades has been our changing view of the concept of intelligence. While intelligence had previously been thought to be predominantly hereditary in nature, we have now come to believe that there is a complex interaction between heredity and environment that produces the product that we call intelligence in the child of five or ten or fifteen (Plomin, 1997).

We have also expanded the scope of the concept of intelligence beyond a measure on an IQ test. Sternberg (1986) has produced the *triarchic model* of intelligence that features the executive and control functions of intelligence, the decision making function not well addressed in the past. Gardner (Ramos-Ford & Gardner, 1997) has stressed multiple intelligences including linguistic, logical-mathematical, spatial, bodily kinesthetic, musical, interpersonal, and intrapersonal. It is difficult to provide a functional definition of high intelligence or giftedness for the schools without first coming to terms with the construct itself.

Perkins (1995) has presented three competing paradigms or models that have all purported to represent intelligence in the past.

- *Neural Intelligence*: A kind of neural efficiency composed of the speed and precision of information processing in the neural system.
- *Experiential Intelligence*: The knowledge we gain through extended experience in academic areas like physics, or non-academic areas such as raising a family,
- *Reflective Intelligence*: The presence of thinking strategies, a positive attitude towards investing oneself in good thinking and metacognitive awareness, and management of one's own mind.

According to Perkins, all of these paradigms are partially correct so now we have the task of combining

<sup>1</sup> The University of North Carolina at Chapel Hill, The Frank Porter Graham Child Development Center, USA.  
E-mail: stagesec@mail.fpg.unc.edu

them to create a new and more adequate paradigm or model of intelligence. We can also note that the presence of *experiential intelligence* and *reflective intelligence* both mean that experience and education can play a meaningful role in the final intellectual development and functioning. While we have previously believed that there was a set proportion of children who would fall into the 'gifted' category (the neural intelligence model) we now see that the limits of high intelligence have yet to be discovered, so we can create experiences and design environments in order to enhance this valuable characteristic.

Gagné (1999) has proposed a breakdown of human abilities based on native and learned experiences that closely resembles the models of Perkins and Sternberg who also stress the interaction of native ability and experiences as resulting in the outstanding performances that we call gifted.

One of the most dramatic pieces of evidence for the influence of environment on the development of intelligence has been provided by Flynn (1999). He examined the retesting of students and adults over time on intelligence tests and found that the IQ scores tend to go up in the retesting over large spans of time. The increases in performance are so great that test constructors have been forced to renorm their intelligence tests to prevent a skewing to the positive end of the test, raising the issue whether we, as a society, are becoming more intelligent or just more proficient test takers.

One of the general understandings that have been accepted regarding intelligence is that it distributes itself roughly along a *normal curve*. But this is surely *not correct* at the ends of the distribution. At the low end, children with mental retardation do not dip lower than two standard deviations below the mean, unless there is some pathological condition present (Burack, Hodapp & Zigler, 1998). However, at the top end of the distribution there are documented cases of students performing as much as six or seven standard deviations above the mean on IQ tests (Morelock & Feldman, 1997)! As in the case of our calling our planet Earth 'round' when in fact it is flat at both poles, intelligence is not really normally distributed at the extremes. There is increasing evidence that the proportions of students at the higher end of the IQ distribution are also much greater than would be predicted by a normal curve of distribution (Silverman, 1997).

There is considerable evidence to suggest that genetics does play a significant role in the development of various intelligences. Studies of twins and adoptive children clearly indicate that some children are born with more potential for learning rapidly than others. These differences apply within various racial and ethnic groups, not necessarily between them (Plomin, 1997); but that is only part of the picture. The rest of the story is that environment and sequential experiences play a significant role in the crystallization of native abilities. If a particular environment allows a

child to have more experiences and to obtain more encouragement from adults and peers whom he or she considers important, then the child's abilities will flourish. Thus boys who are encouraged to work with mathematics and are told (implicitly or explicitly) that excelling in maths is a masculine trait that will develop their native mathematical abilities beyond those of girls who are told that they are not supposed to be good in this subject and that maths ability is gender-specific to males (Reis & Callahan, 1989).

Just as the concept of intelligence had been believed to be one of maturational unfolding within the individual, the concept or model of *creativity* was one in which some special characteristics of the 'creative' child (fluency, flexibility, risk taking, etc.) would be activated given the proper educational settings and conditions. Even as the development of intelligence is now being viewed as an interactive process, so creativity is beginning to be seen as a process that is environmentally interactive as well.

Csikszentmihalyi (1996) views creativity as an interaction among persons, products and environments. This change from focusing intense attention on the 'creative individual' to focusing on the interaction between individual and environment helps us to focus more on how to create a fruitful educational environment. By teaching children how to behave independently and how to search for new ideas we can help many students become more creative, not just those with extraordinary intelligence.

#### *Definition*

With these changing models or paradigms of intelligence and creativity, what has this done to our definition of gifted children? The definition most widely accepted appeared in the report on *National Excellence*.

Children and youth with outstanding talent perform or show the potential for performing at remarkably high levels of accomplishment when compared with others of their age, experience, or environment. These children and youth exhibit high performance capability in intellectual, creative, and/or artistic areas, possess an unusual leadership capacity, or excel in specific academic fields. They require services or activities not ordinarily provided by the schools. Outstanding talents are present in children and youth from all cultural groups, across all economic strata, and in all areas of human endeavor (Ross, 1993).

Note that there is a broader scope to what is giftedness in this definition that was true of past definitions plus a recognition that outstanding talents can and should be found in all ethnic groups. Finally, there is a

recognition that special educational services will be *required* if we expect these students to reach their expected level of educational attainment.

### Characteristics

**Social.** The social relationships of gifted students continued to be a matter of concern despite the continuing evidence (Maysseless, 1993) that they are at least as popular as other students their age. The negative social reaction to students who appear to be outstanding can be judged by the number of unfavorable terms assigned to them. Few children relish being called 'brain' or 'geek' or 'nerd'. Consequently one of the most favorite of strategies is for the gifted students to deny their own giftedness, with the most gifted students being most likely to protest their giftedness (Swiatek, 1995). Many minority students who are gifted feel under additional social pressure to conform to general student norms. It is only those gifted Black students who were less concerned with peer pressure who felt comfortable with their high ability (Ford, 1993).

The self concepts of gifted students have been reported as higher than average. However, this high self image includes 'academic self concept' and it would be strange indeed if students who can easily perceive themselves to be years in advance of their peers do not think of themselves as superior in that domain (Robinson & Clinkenbeard, 1998). When non-academic areas (social or physical self image) are reviewed the gifted students appear only slightly superior to other students in their self image.

**Emotional.** There has been a trend to rethink the role of emotional development in the gifted child. Instead of seeing emotions as separate characteristics to be correlated with intellectual development, the trend has been to view emotions as an integral part of the makeup of the creative and gifted children. Two of Gardner's multiple intelligences represent what has been traditionally viewed as emotional behavior: *interpersonal intelligence*, the ability to understand other individuals; and *intrapersonal intelligence* a person's understanding of one's own cognitive strengths, feelings, and range of emotions.

There has been a revisiting of Dambrowski's concept of *overexcitabilities*, meaning a surfeit of emotional reactions, an intense personal reaction to an experience (Dabrowski, 1967). This passionate and intense response to the world is not seen as a negative, but one, which can lead to extraordinary achievement. Kurcinka (1991) refers in a similar fashion to the 'spirited' child meaning a child with more intense, sensitive, perceptive, persistent, and energetic characteristics. Of course, the more sensitive the child, the more vulnerable to psychic pain. Silverman (1994) reports a common observation that gifted children are more aware than their age peers of the disjunction

between our moral pretensions and our actual behavior.

Dozens of cases on record of gifted children fighting injustice, befriending and protecting handicapped children, conserving resources, responding to others' emotional needs, becoming terribly upset if a classmate is humiliated, becoming vegetarians in a meat eating family, crying at the violence in a cartoon (p. 111).

The intensity of feelings, drive, and passion about one's interests reminds one of Csikszentmihalyi's (1990) concept of *Flow*, a period of intense and single-minded attention to a particular problem or project that is currently under consideration by those who create. This is not to say that all gifted students have such drive and passion and sensitivity, some appear to be no more sensitive than a rock, but the blending of the intellectual and emotional sides is a fascinating and potentially productive area for further investigation.

The creative child, or the child who creates, seems to reveal a constellation of traits and abilities necessary for the innovative mental productivity desired. Davis (1997) assembled some of these traits as independence, risk taking, sense of humor, a fascination with complexity, tolerance for ambiguity, curiosity, etc. Such traits seem important if one is to turn one's back on the traditional lessons and seek other answers to those classroom responses traditionally given.

Terman and Hollingworth early noted that there seemed to be a greater prevalence of first-born children who are gifted. Solloway (1996) studied the lives of social rebels and concluded with the interesting observation that many of them are *not* first born, that first born children tend to be traditional and conservative following their parents' values and wishes. Later born children, in order to seek a niche for themselves in the family, tend to be less traditional and more willing to explore other ways, other answers. We have long been aware of the important role that families play in the lives of gifted individuals, but such findings as the birth order lead us to pursue further the family dynamics for clues as to the nurturing of creative and gifted performance.

In a search for the roots of success and failure for talented teenagers, Csikszentmihalyi, Rathunde & Whalen (1993) introduced a new device for collecting useful information, the Experience Sampling Method (ESM). By using a beeper (an electronic signal) to trigger a student's response at various times of the day we can determine who were his companions, and what he was thinking or feeling, and where he was. It is possible in this manner to gain a portrait of the intellectual and social life of these students.

A study of 394 teacher-nominated, secondary school students yielded such a portrait. Aside from confirming previous findings of the importance of a supportive

family and sensitive teachers the study yielded the following about the life space of talented teenagers.

Talented students spent less time just socializing or hanging out with friends. Instead they shared more active and challenging pursuits with friends, for example hobbies and studying. They learned to modulate attention: more concentration in school and less when socializing, doing chores and watching TV. They also spent a greater amount of time alone, which is essential for anyone building future skills. More solitude and more productive activities probably accounted for more somber weekly moods than average teenagers (p. 244).

In short, these teenagers were creating a productive learning environment for themselves, inside and outside of school, by avoiding or reducing some of the non-functional aspects of teenage society in the United States.

### *Special Populations*

During the last decade in the United States there has been increasing interest in a variety of special populations within the broad general area of gifted education. Among these populations are women, gifted individuals with disabilities, gifted underachieving, and culturally different gifted students.

*Women.* One of the continuing puzzles in this field is why women, making up half of the population and clearly showing academic and intellectual equality in the early grades to males, do not have a stronger track record of adult production or eminence (Feldman, Csikszentmihalyi & Gardner, 1994). Western culture, with its bias in favor of white males, has been considered a major barrier to the further development of women and have stimulated a series of special programs that provide opportunities for the talent development of women (Kerr, 1997; Noble & Smyth, 1995).

A recent review of the topic of gifted women (Noble, Subotnik & Arnold, 1999) identified three major barriers to their progress and productivity that result from this relatively unfriendly culture. First, is the importance of *high self-esteem* necessary for setting important goals, taking risks, and confronting challenges. The authors feel that such high self-esteem is admired when it appears in men, but discouraged as immodest in women.

Second, women are automatically treated as minorities or token members of high-level male-dominated achievement settings. The lack of role models and the 'glass ceiling' which limits promotion to top positions contribute to problems in women reaching potential. Finally, there is the balancing act that women are faced with in juggling family and career. Some adaptation of organizational structures and expectations to take into account this conflict between career and home might be

helpful. The clear advance of gifted women in many different fields will provide role models and success paths that can be followed by the next generation of gifted girls.

*Disability.* We have long been aware of the outstanding accomplishments of gifted individuals who have had a particular physical handicap. Franklin D. Roosevelt, Ludwig Von Beethoven, Helen Keller, etc. are examples of twice exceptional individuals that are easily recognized. But recently, another area of disability has come to the attention of investigators and educators. These are twice exceptional children who are *gifted with a learning disability*. These would be youngsters who may have a variety of perceptual problems, such as dyslexia, that interfere with their learning and sometimes in their even being identified as gifted.

Reis, Neu & McGuire (1995) conducted case studies of twelve college students with learning disabilities who had attained high IQ scores in their youth but who had never been placed in a program for gifted students. These students reported a variety of negative school experiences including (1) their talents not being recognized, (2) an assumption that learning disabilities meant below average ability, and (3) frustration with some teachers' expectations. They also reported that other teachers provided them with support with special lessons and challenging the students at their level of performance. These students revealed high motivation and determination and were aided by a special college program for students with learning disabilities in which they learned various coping strategies, time management schemes, etc.

Coleman (1992) compared 21 matched pairs of middle grade students, one member of the pair being gifted-learning disability and the other average ability learning disability, on their academic coping skills. She found that the gifted LD students had been able to develop on their own a series of positive coping skills that enabled them to perform adequately in school in contrast to the average LD students, who manifested a type of learned helplessness and pessimism in academic situations. She recommended that the development of positive coping skills be part of the curriculum for both gifted and average LD students.

Concern has been felt for what happens to these 'twice exceptional' children when they become adults. Holliday, Koller & Thomas (1999) followed 80 adult rehabilitation clients who were high ability-learning disability subjects. They found that their adult performance was more characteristic of the learning disability dimension than the high ability side of their intelligence, calling for more attention to this combination of characteristics.

Another twice exceptional set of individuals has received attention recently because of the revived interest in autism. A special version of autism appears

to be the 'Asperger Syndrome' where the child has high abilities concomitant with the more traditional symptoms of autism (social distance and isolation, special linguistic patterns, etc.) (Schopler, Mesibov & Kunce, 1998).

*Underachievers.* Ever since Terman called attention to the gifted underachiever (students performing much more poorly than their capabilities would indicate) in his monumental longitudinal study (Terman & Oden, 1947), there have been periodic concerns about finding such youngsters and remediating them. The original findings that such students lacked motivation, had a low self concept, and blamed others for their troubles, seems to be borne out in subsequent studies (see Colangelo, Kerr, Christensen & Maxey 1993).

Rimm (1997) presents a systematic way of approaching such children including individual assessment, family communication, identification of appropriate role models, correcting academic skill deficiencies, etc. Rimm reports widespread success using this model. It should not be imagined however that modification of the coping styles of such students is either quick or easy (see Butler-Por, 1987). After all, it took nine or ten years to form these dysfunctional habits and reversing them or replacing them requires an intensity of effort and individualization of care that few school systems have available to them. Gallagher & Gallagher (1994) described the dance of the underachiever as consisting of "two steps forward, one step back, one step to the side, and pause." The biggest disappointments appear to occur whenever we underestimate the amount of time and effort needed to achieve our goals.

*Cultural Difference.* One of the topics receiving the most attention during the last two decades are differences in ability and achievement between various students from different racial, ethnic, and parental income backgrounds. The finding that there are strong differences in prevalence of giftedness from various racial groups with African-American and Hispanic underrepresented; Asians overrepresented (Robinson & Clinkenbeard, 1998) has been taken as clear evidence of unfairness in the educational system or the culture itself. Dornbush, Glasgow & Lin (1996) in a review of the social structure of schooling point out that:

In a system of mass education, group differences in achievement are seen as a glaring problem. The ideology underpinning mass education implies that equality in educational opportunities leads to equality in educational outcomes, but this expectation has not been realized (p. 404).

Various methods other than traditional intelligence tests have been used in an attempt to find 'hidden gifted' students from minority populations. These

usually take the form of using multiple indices. Frasier & Garcia (1995) pointed out that using multiple measures is not sufficient unless one has a defensible way of combining the results from these measures. Another approach has been to use observation in an enriched classroom along with portfolio assessment that can create a pool of students for further consideration (Borland & Wright, 1994). Others use tests like the Raven Progressive Matrices test as a preferred 'culturally neutral' test and report promising results (Mills & Tissot, 1995). There will likely be many more attempts to provide enrichment for minority gifted students in the near future since it has become a priority of state and federal agencies as well as individual teachers.

### Changing Paradigm of Public Education of Gifted Students

How gifted students are educated in the United States depends in large measure of how we view our public education enterprise, an unwieldy collection of about 15,000 school districts that is overseen by 50 separate states while the Federal government merely supports some research and development activities and provides some financial support for the education of special populations of economically disadvantaged children and children with disabilities.

The portrait of total chaos that many foreign observers imagine as a result of these many people influencing educational decision making from 15,000 separate school districts and 50 states, is overdrawn. While theoretically they could all go off in their own directions, educators often follow the lead of other states or districts so that trends like the Internet in multiple intelligences, or the use of portfolios, quickly become widespread across the country through successive modeling and example setting.

A report released by the U.S. Department of Education, *National Excellence* (Ross, 1993) has had a powerful impact on many educators and school systems. The report indicates many shortcomings of American Education in their dealing with talented and gifted students. Among the shortcomings of elementary school programs were:

- The regular school curriculum does not challenge gifted and talented.
- Most academically talented students have already mastered up to one-half of the required curriculum offered to them in elementary school.
- Classroom teachers do little to accommodate the different learning needs of gifted students.
- Most specialized programs are available for only a few hours a week.
- Students talented in the arts are offered few challenging opportunities.

Some of the shortcomings of the secondary school programs were noted as:

- Appropriate opportunities in middle schools are scattered and uncoordinated.
- High school schedules do not meet the needs of talent students
- The college preparatory curriculum in the U.S. generally does not require hard work from able students.
- Small town and rural schools often have limited resources and are unable to offer advanced classes and special learning opportunities.
- Specialized schools, magnets, and intensive summer programs serve only a fraction of the secondary students who might benefit from them.
- “Sometimes social studies doesn’t challenge me because we mostly just copy things down and go slow.”
- “No it is not challenging, because all we do is take notes, memorize, then regurgitate information for a test.”
- “We are not allowed to be challenged—everything is explained for you with no room for personal views. Sometimes it is not hard enough.”
- “The stories I read are simple and so are the questions. We just read and summarize and answer questions.”

According to the *National Excellence Report* all of this leads to a ‘quiet crisis’ in the words of Secretary of Education Richard Riley (p. iii) and leads to such undesirable consequences as the following:

Compared with top students in other industrialized countries, American students perform poorly on international tests, are offered a less rigorous curriculum, read fewer demanding books, do less homework, and enter the work force or post-secondary education less well prepared (p. 1).

The report urged American educators to pay attention to student excellence in addition to their well-documented emphasis on student equity. Other reports appear to support the National Excellence findings.

The TIMSS report (Third International Mathematics and Science Study, 1997) stressed the low performance of American students compared with students from other countries. This was particularly true at the twelfth grade level. Even gifted students in the United States enrolled in advanced calculus and physics classes were only able to perform at the level of average students from other countries in these subject areas.

One of the common reactions of gifted students in the U.S. to public school is *boredom*. An inquiry of 871 gifted students in nine separate school systems (Gallagher, Harradine & Coleman, 1997) documented the reports of over half of these students that the standard academic subjects lacked challenge. Mathematics and the special enhancement program for gifted students were the only areas in these districts where the students felt challenged.

This group of students was saying, “Give me more work.” Not just more of the same curriculum that has already been too easy for them, of course, but more conceptually challenging materials so that they can use these special abilities that they have. They want to flex their academic muscles. They are as bored as would be a student who has aspirations to be a world class sprinter and has been told he has been entered in a race with a bunch of fourth graders. Some of the comments that these gifted students made were:

*Equity and Excellence.* Many observers have noted the mixed feelings expressed towards gifted students on the part of the general public, and of a subset of professionals. On one hand, we are proud of their accomplishments and honor them through scholarships and various prizes, but on the other hand our envy of their ease of performance communicates itself to these students who wonder what it is they have to do to obtain acceptance. Also, if we see our society as one fueled by competition then helping gifted students means giving them additional advantages over our own non-gifted children.

Two contradictory values have been competing for predominance in American education: *equity versus excellence*. Those who stress equity focus on the vastly different opportunities that exist from one subculture to another in the U.S. They focus on bringing the economically disadvantaged students up to a higher performance level, a level indicated by their potential. There is also a subset of the academic community that sees evil designs in the attempt to provide special help for gifted students. They see this as part of a class struggle. Margolin (1996) suggests that we are providing aid and comfort to the ‘oppressors’ of our society by establishing special programs for gifted students.

Those supporting *equity* (see Oakes, 1985; Margolin, 1996; Sapon-Shevin, 1996) are particularly concerned that many minority students have not had the chance to show what they can do and may be kept out of special services for gifted students because of their limited scores on aptitude tests. In this way, they observe, the majority of high income parents will continue to see to it that their children dominate the special programs.

One of the most influential of trends over the past decade has been the move towards *inclusion*. This is a term from special education describing the proposed integration of children with disabilities with other students in the same classroom. This inclusion philosophy is on the way to replacing the resource room as the primary model for educating children with disabilities (Kirk, Gallagher & Anastasiow, 2000).

Part of the reason for this inclusion movement has stemmed from the overrepresentation of minority children in pull-out programs for children with disabili-

ties leading to suggestions that they were being discriminated against and given an inferior education. Inclusion would at least put such children in the same environment as the mainstream children (Stainback & Stainback, 1996).

There is a similar push for inclusion of gifted students because of under-representation of minorities in separate educational settings for gifted children, again leading to the suspicion that minority students were being kept out of desirable educational experiences (Sapon-Shevin, 1996). Regardless, there seems to be a trend towards educating gifted students in the regular classroom with help from a consultant teacher, or by organizing *cluster groups* (6 to 10 gifted students forming a subgroup in the regular classroom) (Gentry & Owen, 1999).

The general dissatisfaction of parents with the status quo of public education has led to the development of several alternative environments. *Charter schools* (schools that are free from the bureaucratic regulations of the regular school but with its same responsibilities) have been one way in which parents of gifted students have tried to gain more decision making control over the school program.

Another device is *magnet schools*, so-called because they present a visible program in certain educational areas such as advanced mathematics, or art, or creative writing, and thus draw students interested in their special program. Though we are currently short of evaluation of such programs, the informal messages from magnet school students has been largely positive.

A final change of setting has been *home schooling* whereby the parents agree to help the student learn necessary facts and master skills in exchange for being allowed to keep their child at home. The growing prevalence of computers in American homes has helped this Home School movement, which began as a move by some parents to give their children a religious orientation and background that they could not get in the public schools. In the case of parents of gifted students, home schooling has been used to allow the child to go forward on his/her own and not be tied to an inappropriate curriculum or educational setting.

Oakes (1985) complained that ability groupings for gifted students have failed to show any academic superiority and wishes to have all students educated together. At least in this fashion all would be getting the same education and no special opportunities would be given to upper middle class, white students. On the other hand, Kulik & Kulik (1991) have analyzed many grouping studies and have come to the conclusion that when grouping is accompanied by advanced conceptual curriculum, the ability grouped programs show a clear advantage over the heterogeneous classroom.

During the Cold War with the Soviet Union, programs for gifted students profited from the fears and anxieties of the public who felt we were falling behind

in our educational programs, particularly those in mathematics and the sciences. Given a competition for national survival, all necessary steps to improve our performance were acceptable, particularly for those gifted students who had the potential to make a difference in scientific discoveries and engineering prowess. With the Cold War over, there is less of a press to challenge our brightest students although some efforts have been made to substitute Asian countries, such as Japan, as an economic competitor in the information age.

The discovery that there was an under-representation of African Americans, Hispanics, and Native Americans in advanced programs fueled the suspicions of observers who felt that these advanced programs and services were being reserved for those children of families that possessed political power and could influence the decision making as to who will receive special services. This perception of a love-hate relationship with the general public has caused some gifted students to reject special programs and flee to the anonymity and social safety of the general education program. Other gifted students complain, however, that they are not being challenged in their classrooms and have found it too easy to attain high grades with minimal effort. While we honor the athletes who give '110% effort' and whose exertion lead them to outstanding performance we do not often demand the same level of effort from the intellectually gifted. The result is similar to that of a six-cylinder car running on four cylinders, adequate for some purposes but far from its potential.

### The Paradigm of Educating Gifted Students

Our changing view of intelligence, and what should be a good public school education, has inevitably influenced how we provide special services for gifted students in the schools. These changes occur in *where* the student is educated, *what* the student is taught, and the type of *skills* they are expected to master.

*Where.* There have been a wide variety of efforts designed to counteract the lack of challenge provided to gifted students in the typical educational setting. One of these involves a drastic change in the educational environment itself. A number of states have established special residential schools designed to provide stimulation for highly talented students at the secondary level (Koloff, 1997).

These schools have elaborate procedures for selecting the students involved, and they bring together a faculty with special expertise in the curricular areas emphasized by the school, often science and mathematics and art that seem to be the central focus of many of these programs. These schools provide an advanced curriculum of college level content and difficulty to these students who, often for the first time, find themselves among other students with similar abilities,

interests, and aspirations. The results have reported great student and faculty enthusiasm, a laboratory for instructional strategies, (Stepien, Gallagher & Workman, 1993) and a reputation for excellence. Eleven states now have created similar schools for the purpose of challenging the top students in their community or state.

Another approach using existing institutions was developed by Julian Stanley, called the Study of Mathematically Precocious Youth (SMPY). The program was initiated at Johns Hopkins University and now includes four other universities. Its purpose is to identify youth with extraordinary talent in mathematics through administering tests while the youngsters are in their early teens. While originally viewed as a talent search, the SMPY became a base for student acceleration and, through special summer programs, allowed talented students to earn credit for advanced mathematics courses.

Benbow & Lubinski (1996) have reported the beginnings of a fifty-year longitudinal study to determine the fate of SMPY students identified in the talent search. Some preliminary findings indicated substantial later academic success and student satisfaction with the program. The talent search portion of SMPY was also responsible for the discovery of great gender differences in mathematics between girls and boys and has been one of the leading forces to build special math and science programs for girls in this country (Lubinski & Benbow, 1994).

#### *Ability Grouping*

Several major attempts have been made to determine if placement, by itself, seemed to be of significance in academic achievement. The Learning Outcomes Study involved over 1,000 students. The teachers worked in a variety of settings providing special services for gifted students from fourteen school districts in grades 2 and 3. These students were placed in four separate settings: *Special School, Special Class, Pull-Out, and Within-Class* settings. The students were tested at the end of the year with the Iowa Test of Basic Skills and a variety

of attitude and self-concept measures (Delcourt, Loyd, Cornell & Goldberg, 1994).

The results did indicate major achievement differences between the four groups with the advantage accruing to the special schools and special class programs. There also were differences in self concept with the highest measures obtained by the gifted students in the heterogeneous classrooms. This is a phenomenon noted before. Your social reference comes from the peer group in which you are assigned. If you are surrounded by peers of relatively equal ability to yourself your self image is likely to be lower than if you have peers who are manifestly lower in performance than yourself. There were no group differences obtained on social acceptance, however. Although the gifted youngsters in this study were quite young there did seem to be an advantage in grouping them together, allowing the teacher to press on to more challenging and complex materials and topics with these students.

Table 1 provides a breakdown of desirable practices in gifted and general education that seem to be supported by solid research (Shore & Delcourt, 1996). Many educators have pointed out that various educational strategies that have been recommended for gifted students could be profitably used for all students. Examples of such approaches are enrichment, inquiry, discovery, problem solving, problem finding, etc. All students profit from the challenge of doing their own thinking instead of memorizing predigested content.

For gifted students the content level involved in the discovery and problem solving could be at a higher abstract level than possible for the average student. The high level curriculum noted in Table 1 as uniquely appropriate for gifted would be an example of raising the conceptual level of the curriculum, such as studying various forms of government through the ages rather than just mastering the current workings of government in their own country. Also Shore and Delcourt note that *ability grouping, acceleration, and differential programming* are particularly useful for gifted students, mainly because they have already mastered the standard curriculum provided in general education.

*Table 1. Desirable Practices In Gifted And General Education..*

Uniquely Appropriate for Gifted	Effective with Gifted and General Education
Acceleration	Enrichment
Career education (girls)	Inquiry, discovery, problem solving, and creativity
Ability grouping	Professional end products as standards
High level curriculum	Microcomputers
Differential programming	

Adapted from Shore, B. & Delcourt, M. (1996). Effective curricular and program practices in gifted education and the interface with general education. *Journal for the Education of the Gifted*, 20 (2), 138-154.

More and more educators seem to be convinced that differentiating the standard curriculum is the key to effective education of gifted students but examples of such differentiation are few and far between. Gallagher & Gallagher (1994) have detailed four different ways in which the standard curriculum might be modified for gifted students. Such modified content can represent acceleration, enrichment, sophistication or novelty.

- (1) *Acceleration*. The material presented to the gifted student may be drawn from the established curricula of a grade or more in advance of the students' current status (e.g. algebra in the seventh grade).
- (2) *Enrichment*. The same curriculum goals are used as for the regular class members but the material is extended and more in depth (e.g. studying the diaries of the Lewis and Clark expedition as the class discusses westward movement).
- (3) *Sophistication*. The material presented to gifted students is at a higher level of complexity, representing systems of knowledge, than that given to the regular student (e.g. studying the laws of Physics and their applications).
- (4) *Novelty*. Material that is unique to the regular curriculum but which has some interest to gifted students (e.g. the study of the stock market and its operations).

The proliferation of high academic standards recently published by professional groups in mathematics, history, science, etc. have proved another anchor point for differentiated curriculum for gifted students.

### *Productive Thinking*

One of the continuing arguments about productive thinking is whether we can instruct students in the general heuristics of problem solving or problem finding so that such mastery can then be transferred to whatever subject matter the student has to be dealing with at the moment (deBono, 1986). Much of gifted education of recent origin has held that assumption. Teach for creative thinking and the student will be creative in whatever topic area he will operate in (Torrance, 1964). An alternative position is that the student should be taught heuristics only within a particular field and that such complex strategies will be useful to him/her only within that field, with the transfer of these skills to other fields to be mainly limited or non-existent.

The field of artificial intelligence seems to provide some useful insight to the problem. There was an earlier attempt to develop a 'General Problem Solver' designed to use general principles to address a wide variety of problems in mathematics, chess playing, etc. (Newell, 1990). Basically, the 'General Problem Solver' became less useful in an area such as chess playing than were programs that had deliberately been written for only chess playing.

A series of studies contrasting the strategies of experts versus novices in physics, medical diagnoses, chess players, etc., tended to indicate that it was the knowledge base of the experts that allowed them to respond more effectively in problem situations. Perkins & Soloman (1989) summarize the contending parties as follows:

General heuristics that fail to make contact with a rich domain-specific knowledge base are *weak*. But when a domain specific knowledge base operates without general heuristics, it is brittle—it serves mostly in handling formulaic problems (p. 23).

They conclude by arguing for an approach that calls for the intimate intermingling of generality and context-specificity in instruction. The message for us in gifted education would seem to be that if we wish to teach the student problem solving skills or creative thinking strategies we should do it within the context of a strong content base.

The desire to blend together the processes of productive thinking and sophisticated content in an integrated curriculum model is presented by VanTassel Baska (1997) in three dimensions: (1) emphasizing advanced content knowledge that frames disciplines of study; (2) providing higher order thinking and processing; and (3) focusing learning experiences around major issues, themes, and ideas that define both real world applications and theoretical modeling within and across areas of study (p. 128).

Examples of such models may be found in the problem based learning model and the enrichment triad model that follow.

One of the increasingly popular instructional strategies being used in American education is *problem-based learning* (PBL). This approach is a distinct departure from the didactic lectures and reading often used in our schools and universities. There are three critical features to the PBL approach (Stepien, Gallagher & Workman, 1993):

- *Learning is initiated with an ill-structured problem.* (This is one in which the solution to the problem is *not* embedded in the statement of the problem itself as would be true in an arithmetic reasoning problem)
- *The student is made a stakeholder in the situation* (may be asked to play the role of a legislator or scientist forced to make a decision about the situation)
- *The instructor plays the role of metacognitive coach* (helps guide the student in their search for important knowledge by helping with the organization of information).

This PBL approach appears to heighten student interest and motivation without losing content mastery for the subject matter (Gallagher & Stepien, 1996). Since students of varying ability levels can respond to the

problems at various intellectual levels this PBL approach allows for challenge for gifted students without losing the interest of other students.

The Renzulli Enrichment Triad is another instructional device designed to help students become more productive thinkers. The three stage approach is to: (1) introduce students to major topics, (2) provide students with methods and skills for finding answers, and (3) take a real problem and conduct an independent investigation using skills learned in step 2. Table 2 gives an example of this approach.

Baum, Renzulli & Hebert (1995) report positive gains in attitude, achievement tests for a group of seventeen underachievers (grades 3–9) who were educated through the Enrichment Triad approach. But how will we know whether our differentiated environments, content, or strategies have achieved their goals?

#### Accountability

One of the most persistent reform movements in education in the U.S. has been that of accountability. A central question in this endeavor is, "Do the schools achieve the instructional goals that they set for themselves?" Since there is strong suspicion in the minds of many that the schools do not achieve instructional goals for gifted, a complex system of testing is often mandated to determine the achievement of students in various content fields (mathematics, history, etc.). Aside from the unwarranted assumption that student performance is the exclusive responsibility of the school, instead of the psycho-social-cultural and economic worlds in which they exist (Gallagher, 1998; Evans, 1999) such broad scale attempts at evaluation must also assume common goals across schools and districts. Once one goes beyond simple skills such as reading and arithmetic, that assumption of common instructional goals and experiences also suffers.

Does this general education accountability movement aid educators of gifted students in their own attempt to determine if their special services or programs are having a positive effect on the students? Not really! There are problems in trying to apply general goals to gifted education which, after all, is supposed to have been differentiated from the average instruction. Gallagher (1998) notes several problems in evaluation:

- *Ceiling Effects.* Standard measures for average students will find the gifted student performing at the top of the test and we will only know that the gifted student has mastered the material on that test, we will not be testing their depth or breadth of knowledge.
- *Content Emphasis.* Part of differentiated content for gifted means that they may be studying Ancient History of Egypt or Space Exploration. If these topics are not on the standard examination, how will we know how the student has performed?
- *Content Complexity.* Most of the standard tests focus on factual knowledge or simple association and will not test the student on elaboration of thinking or depth of understanding of the subject again underestimating the gifted student's mastery of the topic.

One key to the proper assessment of programs for gifted students is to clearly state the specific instructional goals and a description of the educational procedures by which these goals are to be met (Callahan & Caldwell, 1995; Borland, 1997). There has been an attempt to employ *authentic assessment* (using measures that link to the instructional goals such as writing an essay for a measure of writing skills) and *performance assessment* (if the student produces a product such as a scientific experiment as part of his assignment then that product is the proper basis for careful evaluation). Such efforts then become qualitative (the use of human judgment in evaluation) in

Table 2. *The Renzulli Enrichment Triad: How Did Our City or Town Begin?*

Step	Teacher Activity	Student Activity
I	Exploratory activities that introduce students to a major topic. Field trips, special speakers, etc., help to stir students' interest	Students are asked to consider why their town started and developed here. They may read old newspapers and documents to stir their curiosity.
II	Students are introduced to methods by which they can find answer to these questions.	Students learn how to find historical documents, how to use school and community libraries, how to deal with conflicting information.
III	Students take a real problem and conduct an independent investigation using some of the skills they learned in Step II.	They can use diaries and reports to study the role played by the initial settlers in establishing the community. They can study the role played by trade via the roads and rivers that shape community growth.

form but the qualitative methods approach is becoming increasingly well accepted (Wiggins, 1989; Nielson & Buchanan, 1991).

While well crafted evaluations for programs for gifted students are rare at the present time, they are not non-existent. Evaluations of new curricula in science and language arts for gifted students have shown meaningful gains in cognitive growth through a mix of quantitative and qualitative measures used (Hughes, Van Tassel-Baska, Boyce & Quek, 1994). Evaluation is a growth industry in American Education and will be much in evidence during the next decade.

### 2000 and Beyond

What lies in the immediate future for gifted education in the U.S.? Prediction is always a dangerous business since there are often *wild cards* that appear (events that cannot be predicted in advance that change the landscape) but some trends seem evident.

*Intelligence.* We have had two decades of exciting work on delineating what we mean by high intelligence and we would seem to be only in the midst of that work now. We should count on more interesting findings about the link of emotions and intelligence or what controls the *executive function* by which we make decisions, etc. and above all what we can do as educators to enhance its development.

*Young Gifted.* Most of the educational efforts over the past few decades for gifted students have started in the age range of 8–12, after the child has fairly well established patterns. Our realization of the flexibility of intellectual growth enhances the need to look at the development of these children earlier. Education is also in a slow and painful, but inevitable, process of extending its influence and responsibility to four-year-olds and perhaps to go to three year olds as well. They will be responsible now for young gifted students and will have to learn new approaches appropriate to that age level.

*Culturally Different.* We have spent a decade of attention on how to find the ‘hidden’ gifted students from culturally different environments but relatively little time in trying to enhance the intellectual development of these bright students once we have found them. This trend should be reversed soon. A much greater effort should be made in documenting attempts to upgrade the abilities of culturally different gifted, one of the major untapped resources of our society.

*Differentiated Curriculum.* There has been a realization that moving bright students from one environment to another is a relatively useless endeavor unless, at the same time, we modify the basic curriculum that they receive. Much effort has already been started on blending sophisticated content with instructional strate-

gies designed to help the students master complex ideas and systems. We should see a blossoming forth of a wide sample of model curricula in many content areas that will be of substantial aid to the teacher of gifted students.

*Gifted Women.* Ever since there has been a significant effort to attend to the special needs of gifted girls we have seen an upturn in their performance. Since this slice of the population turns out to be slightly more than 50% of the entire population, there would seem to be much to be gained socially as well as individually to continue our efforts to help girls “be the best that they can be” in the educational setting and later in the workplace and family.

*Support Services.* Just as gifted education has been influenced by more general trends in education so should they be influenced by a coming change in the organization of special education in the schools. There is a strong trend to bring a wide variety of auxiliary services into the schools (social work, mental health, special education, health, nutrition, etc.). It seems likely that the support services (including the psychologists, counselors and special teachers serving gifted students) will probably be brought under one department of special services within the educational complex of the school district. Whether this will be a favorable move for gifted students remains to be seen.

*Public Policy and Excellence.* As noted in this report, the United States has been wavering back and forth between two important educational goals, *equity* and *excellence*. The last two decades has seen the pendulum swing strongly in the direction of *equity* as we have become aware of the many problems facing young children growing up in poverty and social disorganization and most of our initiatives have been designed to use the educational system to counterbalance some of the negative social forces. The new millennium is likely to see a swing of that pendulum back to more emphasis on *excellence* as we become more and more embedded in the information age. It becomes more and more important for bright students to be using their abilities to stimulate this new era with economic and political productivity. But this will not happen if the current ‘laissez faire’ approach to gifted students continues into the next decade.

# A Study of Education for High Ability Students in Canada: Policy, Programs and Student Needs

Janice A. Leroux<sup>1</sup>

## Introduction

Elementary and secondary education in Canada is currently in a state of major change. Since education in Canada is the direct responsibility of each province and territory, the changes are a reflection of the broader state of the economy and governments' emphasis on economic restraint. Ten years ago there were numerous provincially supported programs for gifted students across all grade levels. The promotion of excellence was a public goal and a wide range of services for these students, along with other exceptional students with special needs, was the prevailing pattern.

With the election of a number of more conservative provincial governments across the country, support for education (and concurrently, health care) began to wane. Economic and technological advancement became the current goals espoused by educational reformers in the provinces (Government of Canada, 1991a, b). A national trend towards inclusion and 'least restrictive environments' became the philosophical argument driving educational dollars.

Providing a range of services, although still on the books in many provincial regulations, was less in evidence as high ability students spent more time in regular classrooms. Educational innovations questioned the value of pull-out programs and stressed the notion of inclusion for all (Lipsky & Gartner, 1989; Pearpoint & Forest, 1992).

While student abilities in the classroom were showing greater variability, teacher competence and commitment to such diversity was declining (Lovitt, 1993). Yet at the same time, within faculties of education, teachers who were being exposed to the needs of special education students, received few, if any, training modules focusing on gifted and talented students. Teacher education and the need for advanced qualifications in education of gifted students became less popular in the faculties of education; this trend appeared all across the country.

It should be stated that education is mandatory for all children up to the age of 16, with exceptions made with parental consent at the age of 14. All schooling is free up to the age of 18. Only at post-secondary levels does the federal government in Ottawa provide financial support to subsidize education. Thus, each province is free to plan policy, implement change and provide support services for its student population. The results are quite varied from region to region in this land that is geographically the largest country in the world.

In order to determine the current provisions for gifted students, in 1998 a survey was carried out across Canada asking school boards, provincial Ministries of Education and Faculties of Education. Because of the vast numbers of school boards in each province, a purposive sample reaching a cross-section of geographic areas was surveyed. Seventy-eight responses were received from nine provinces and the North West Territories. Fifteen responses came from faculties of education in eight provinces. Ministries of Education from the North West Territories and three provinces were also received. The total of survey returns represents a 42% response rate. The following chapter reports on the conclusions of the survey.

## Ministries of Education

All the provinces and territories stated that there were provincial mandates to provide equal educational opportunities for all students. Policy statements ranged from Individual Education Plans (IEP) required for all identified exceptional students (New Brunswick, Yukon, and Ontario) to program policies developed as required at the local board level (Manitoba). There appeared to be consensus about the right of all students to an appropriate educational program, however, the form for establishing and conducting such programs was not legislated uniformly across the country.

Across Canada, 'Gifted' for the purposes of legislation, is usually defined as intellectual ability. Hence, there is little attempt to accommodate special abilities such as creativity, kinesthetic or psycho-social talents. Any legislated services are based on demonstrated

---

intellectual aptitudes generally identified at the local school board level by a variety of assessment measures such as the Canadian Cognitive Abilities Tests, the Revised Wechsler Intelligence Scales, teacher, and in some cases, parent nominations.

As a result of varying educational policies, program offerings for high ability students differed from province to province. Some Ministries reported no separate legislation for programs for these students beyond what was available in the regular classrooms (New Brunswick, Yukon, North West Territories). Another Ministry, similar to Alberta and Ontario, reported legislation under special education services that allowed for mandatory education plans, yearly reviews of programs and services, or district supervisors responsible for enrichment services (New Brunswick). In general, it appeared that while equity in education is publicly legislated policy across Canada, programs and services for gifted children most frequently are subsumed in the regular classroom because there is no consistent legal mandate or support for a wide range of other services.

When asked what research was available to determine the effectiveness of such policies, all the respondents reported there were no provincial research or evaluation programs in place. Manitoba and the North West Territories, similar to Ontario, indicated that local educational districts provided various school-based measures such as parent conferencing, or curriculum review studies. Thus, if local school boards have advocates for high ability students within the educational and parental community, then indications are that some educational provisions for a range of services and accountability might occur. This issue is developed further in the survey results from individual school boards.

Funding for establishing and conducting programs for gifted students is generally not allocated from provincial Ministries of Education. All four provinces and territories reported that block grants were provided to school districts which in turn were responsible for education of all students. Any transportation, supervision, special programs or personnel for services for identified gifted students have to be budgeted by the local education authorities in each school district. All respondents reported that such funding was optional for high ability students in their areas.

When asked about pre-service education requirements and professional development training available for teachers of gifted students, all respondents said there was no specific training mandatory for teachers in their provinces or territories. Courses were optional, general special education upgrading qualifications were encouraged, and district level professional in-service was available. In all reports, however, nothing was mandated regarding qualifications for teachers responsible for gifted and talented students in the provinces. School systems were under no obligation to

hire teachers with special educational certification for teaching gifted students.

When asked to outline future plans for educational provisions for gifted and talented students in their province or territories, respondents described: (1) the development of curriculum documents (Manitoba); (2) the development of teacher training modules, with an emphasis on Renzulli's Enrichment Triad Model (New Brunswick, Yukon); (3) the organization of in-service workshops and professional development for teachers (North West Territories). The latter are also current initiatives underway in Alberta and Ontario.

In summary, while Ministries of Education are the ultimate authority responsible for education of high ability students, much of the actual planning and implementation is the responsibility of local educational authorities. Ministries do not set down qualifications for teachers of the gifted, nor mandate levels of training. Little specific funding is set aside for projects or transportation related to gifted students, teacher in-service development is optional, and curriculum documents are left to the discretion of local school boards. In addition, research and evaluation relating to gifted and talented students is rare at the provincial level.

### Local School Boards

Nine provinces and one Territory making a total of 78 districts, responded to the survey. Questions ranged from identification and placement criteria, types of programs offered for gifted students, criteria for teacher selection, to community collaboration. The following provides a synopsis of the data both from demographic and open-ended responses received.

The majority of the school boards which responded indicated that there were special provisions made for gifted and talented students in their jurisdiction. About 80% of the school districts reported providing various types of school programs at various times during the school day. These programs included services such as:

- enrichment classrooms, full or part-time
- independent study programs
- advanced placement (for secondary schools)
- subject acceleration
- pull-out programs
- mentorships with community and university personnel
- regular classroom with enrichment
- different programs within regular classroom

Grade acceleration of high ability students was available in over 70% of the school districts, although a number of respondents wrote that this was only offered 'occasionally' or 'rarely'.

Community activities such as Science fairs, Music festivals and mini-course enrichment programs at a local university were considered in some provinces as

part of the school program and hence, reported as types of programs offered. Ontario, Alberta, British Columbia, and Saskatchewan indicated that for advanced secondary school students who were motivated, the International Baccalaureate Program was also provided as a means to accelerate gifted students. This allowed them to gain academic credits for university while still in their secondary school environment.

It appeared that most school boards supported the concept that opportunities for enriched learning should be available to children who demonstrated intellectual ability and motivation to learn. The form that programs took was extremely varied, with most activities taking place at the school level in a home classroom among groups of normative ability children.

It should also be noted that prior to 1993 in larger provinces such as Ontario, Saskatchewan, Alberta and to some extent British Columbia, homogeneous classes of gifted and talented children were funded in many urban centres. Sometimes these classes were designated 'pilot classes', but they continued to operate for over 15 years because parents and teachers supported this placement option.

Over the last seven years, however, the rapid growth of special needs, at-risk students, and increased societal demands for fiscal accountability across all sectors of society in Canada, has led to extensive restructuring of school programs. Educational, health and welfare resources were reduced at all levels, both provincially and federally. In the midst of such changes, the wide range of program services for high ability children began to shrink. Successful congregated classes for these students were among the first programs to be cancelled. It remains for a coalition of new advocates among parents and teachers to ensure access to congregated ability classes for our current and future gifted students.

Part of the reason there seems to be no consistent policy for gifted and talented children across each province is that individual school boards have autonomy to plan and implement school programs according to perceived local needs. When asked if the local school authority had a written policy for the education of its high ability students, over 75% of the school districts reported no such policy was in place. Ontario, the province with the highest number of districts with school provisions for gifted students (90%), reported the highest percentage of districts with specific policies in place (67%). Considering that Ontario has had legislation since 1980 recognizing the legal rights of education once defined as 'Exceptional-Gifted', it is somewhat surprising that a third of individual school boards report having no policies to accommodate gifted students.

Jurisdiction of programs for gifted students appeared to be divided between special education and curriculum departments of the local school authorities. Responses indicated that 63% of school boards

assigned responsibility for programs to the special education department, while 36% reported giving jurisdiction to the curriculum department. There seemed to be no relationship between whether there was a policy in place for education of gifted students and the assignment of program jurisdiction.

A variety of other administrative patterns were also listed under the category, 'Other'. These included assigning administration of programs to such sections as individual school staff and support services, and student services. Once again such data highlight the autonomy of the majority of local school boards across the country.

When asked to rank the importance of identification procedures used in the individual school boards, the three most important measures were: (1) teacher selection, (2) individual psychological tests, and (3) group academic tests. Since most of the school boards currently use a variety of procedures for screening and identification of gifted students, it is not surprising that parent nominations and peer nominations also ranked closely with group academic tests in the majority of school boards. However, it should be noted that the latter two measures, when used in local school systems, do not carry the same weight or ranking strength as either individual or group psychological assessments.

Once identified, programs for high ability students begin in late primary grades (ages 9–10) across the country. In very rare cases, such as the Halton Board of Education, and the former Ottawa School Board in Ontario, younger students may have access to congregated enrichment classes. Generally, regular classroom teachers are expected to know the needs of their students and provide enrichment to complement the regular curricula.

Only Ministries of Education (Special Education branches) in Alberta and Ontario have issued curriculum Guidelines with special resources materials to help teachers work with gifted students in these provinces. The majority of school boards reported that they had developed their own support documents and resource materials for these students. It can be assumed that in the 22% of school districts that did not report having their own curriculum materials for gifted students, that the teachers carried a great deal of responsibility for locating and implementing special programs.

Before the new wave of economic utility hit Canadian educational systems, there were often district wide consultants available to offer resources support for teachers in the classroom. These were teachers trained in special educational needs of high ability students and available to a family of schools for help with enrichment materials, teaching strategies, reading resources, etc. At the current time, these consultants are generally teaching in regular classes once again, or have been reassigned to work with teachers who have special education students with disabilities and limited learning needs. Only 20% of the school boards

reported still staffing a consultant responsible for programs and teacher support for gifted students.

On the other hand, over 60% of the school boards reported using a special assignment teacher in their schools as the personal responsible for the programs and teaching of identified gifted students. This person might be a school librarian, a principal (head teacher) who taught part-time, a special education teacher, or other classroom teachers designated responsible for gifted students part of the week. The program delivery and personnel assigned to serve gifted students in extremely varied across the provinces.

Likewise, transportation, a major concern in school districts that are as large as some European countries, is a concern and source of restriction for accessing special programs for gifted students. Less than 40% of the reporting school boards provided transportation to any special classes for these students. Several of the large urban districts (less than 5%) reported issuing bus passes for students in special programs.

If a school was noted for its special programs, but was too far away, then generally the onus was on parents to provide transportation. That assumes that an open boundary policy allowed this choice to parents and their children. Not all provinces or districts allow cross boundary school placements without a fee, and there have been cases of litigation where parents of gifted children have sued (and won), the right to have a child placed in another jurisdiction at no cost and with transportation provided (Leroux, 1990).

The result of transportation restrictions means that if a local school does not provide special programs for gifted children or adolescents (and this often applies to middle and secondary school students), then the students cannot access a wide range of services and must accept the limited programs available in their community school. Because transportation costs are a large portion of school board budgets, individual schools are expected to serve a growing range of special education needs. More and more we see gifted students integrated into regular classrooms in their local schools, served by hard-working teachers, but with educational provisions that are often sporadic and underfunded.

The issue of funding for programs and services for gifted students is difficult to determine. Not all school boards reported information as to costs per pupil or for program development. Because responsibility for these students comes under a variety of categories such as special education, transportation, curriculum departments and staffing, to name a few, a clear picture does not emerge across the provinces. Where congregated classes are reported for gifted learners, class size ranges between 18 to 25 pupils. In general, it appears that school districts are extremely creative in attempting to access resources, modify curricula, fund field studies to extend the curriculum, promote cooperative programs, and use community mentors and volunteer

experts, in efforts to provide unique educational experiences at reduced costs for their high ability students. It remains for future research to assess the results of these endeavours.

All of the school boards reported providing in-service workshops for teachers on issues relating to education of gifted students. In addition, over 90% indicated that they provided opportunities for teachers to go to conferences and workshops to up-grade their knowledge of the field. Several districts also noted that workshops and in-service activities were organized when teachers requested such support. No information was gathered, however, as to the frequency of these training provisions or to the number of teachers who actually attended. If teachers are primarily responsible for adapting and providing programs for individual students, then training assistance is a key component for success. Once again there is great variability in the degree of expertise available for and utilized by, educators responsible for serving high ability students in Canada.

It was interesting to note that when asked to rank criteria important in the selection of teachers for gifted and talented students, the following ranking represents the collective response:

- |                               |   |
|-------------------------------|---|
| • commitment                  | 1 |
| • creativity                  | 2 |
| • flexibility                 | 3 |
| • personality/human relations | 4 |
| • intellectual ability        | 5 |
| • academic qualifications     | 6 |

Although the above ranking reports the average of responses, it should be noted that many school boards ranked many of the traits of similar importance. It was evident that many of the districts wanted personnel with a combination of the listed qualities. Since the survey was completed by one person in a district, however, rankings might have been arbitrarily assigned. Caution should be taken when interpreting this item.

When comparing this ranking with that of a similar survey done by the Canadian Educational Association in 1980 (Borthwick, Dow, Levesque & Banks, 1980), the item 'flexibility' was then ranked number one, and 'intellectual ability' was ranked number 4. This may indicate a small shift in importance over the years, but generally the criteria have remained quite constant in the expectations of educators responsible for the selection of teachers for high ability students.

The last item on the survey asked how the school boards evaluated programs for gifted students in their systems. The following processes and frequency of responses were indicated:

- |                                     |     |
|-------------------------------------|-----|
| • system review by the school board | 50% |
| • informal evaluation               | 50% |

• teacher assessments	40%
• products produced by students	35%
• student achievement	40%
• parent assessment	10%
• no evaluation reported	50%

Figures total more than 100% because most respondents described a variety of evaluation processes at work. In addition to the above items, one school board in New Brunswick indicated that guidance personnel were also part of their evaluation process.

Where boards did not have a system-wide process for program evaluation, individual schools and teachers were responsible for evaluation procedures. This 'informal evaluation' was for the purpose of adjusting programs and rationalizing services at the school level. This seems to indicate that many school systems still leave the responsibility to individual teachers to meet the needs of high ability students.

Also, the fact that school boards in seven provinces reported having no evaluation procedures for their gifted programs raises a number of questions. Where is the accountability? Who is ultimately responsible for program quality, review and revision? Why are there no consistent policies and procedures from the central school administrations and provincial Ministries of Education?

Provincial Special Education departments in Ontario and Alberta require that yearly reviews of individual pupil placements and educational programs be conducted and reported by school boards for students identified as gifted. These proceedings, involving parents along with school personnel, are costly and time-consuming. Could these be reasons why more provinces have not mandated formal evaluation for services for gifted students?

It should be noted that currently Alberta is opening educational options to allow school boards to establish charter schools. In 1998 in Calgary, parents supported the opening of three charter schools to serve gifted children in the city. This was a direct result of a public review of the city's board of education. Evaluation results indicated that special needs programming for gifted students was insufficient and ineffective in the regular school system. Armed with such information, parents took the opportunity to hold administrators accountable.

Educational administrators have an important role to play in ensuring the quality of education for all students, but without systematic program evaluation, the onus falls back to the classroom teacher again to provide assessment and evaluation to justify continuation of services for high ability students. It is evident there is a great need for consistent program evaluation across the country and accountability to parents may be the powerful force needed for renewal.

In summary, school boards in the provinces have the major responsibility for educational policies, programs

and services for gifted learners in their jurisdictions. There is great diversity in educational provisions across Canada. Local budgets drive the availability of services and resources: the increase of inclusive, least-restrictive environments for education fuels the placement for gifted students. Regular classroom teachers are most likely to be the primary educators responsible for program development and implementation. Educational qualifications for teaching gifted learners is the decision of individual school boards.

Though a wide range of educational programs and services are available in most school boards, only Ontario has legislation which mandates such services for gifted students. School boards are creative and diverse in their development of programs, utilization of community resources and provision of services. The percentage of gifted students served varies from 1 to 10% across the country, with urban centres reporting the largest numbers of students.

Program evaluation and yearly reviews are, for the most part, sporadic, and dependent on the policies of local school authorities. In some urban centres, notably Ottawa, Calgary, and Toronto, parents have been valuable advocates for enhanced program services to meet the needs of gifted children. The current movement towards economic utility has spilled over to education and school boards are reorganizing and amalgamating many services for these students. There is a need for strong advocacy for gifted students lest they be lost in the turmoil of current educational reforms in Canada. As well, research is needed to show the complex links among teacher effectiveness, programs and groupings, and special populations of students in order to inform any proposed educational changes.

### Faculties of Education

The responsibility for teacher preparation lies with faculties of education in the ten provinces of Canada. In general, knowledge and training in the area of high ability learning is incorporated into the broad field of special education for new teachers. This section will summarize responses to the survey which were received from 15 faculties in eight provinces.

The questionnaire asked if programs in teacher education were offered at the faculty of education. Responses indicated that 86% of the institutions did not have specific courses available for the beginning teachers. The fact that some faculties provide a minor focus on gifted and talented students is laudable, but this situation is not extensive. Universities in British Columbia, Alberta, Ontario and Quebec described some credit courses available, but these are elective courses which means that not all undergraduate teachers would receive this training.

Descriptions of program offerings ranged from one module in special education studies, to an optional three-credit course concentrating on the gifted learner.

When studying about special needs students, the beginning teachers would be encouraged to explore the range of abilities of various populations of exceptional children or complete a case study of a special child during the practicum weeks. However, because this remains an option, there is little reason to suggest that all beginning teachers learn about gifted students. Such options are a prevailing pattern in undergraduate programs at the faculties of education.

When asked if a graduate program in special education was offered, 60% of the faculties responded 'Yes'. However, majoring in education of gifted learners is rarely available because no institution reported a wide range of graduate courses focusing on this concentration. Of the total responses to the survey, 54% indicated there were no actual credit courses available in this field. Individual faculties, such as those in McGill University, Bishops University, and Universities of British Columbia, Alberta, Brandon, Ottawa, and Toronto, offer a graduate course in education of gifted and talented students. Since one or two courses do not constitute a total program, it appears that at the graduate level in Canada there is little opportunity to specialize in the education of high ability learners.

On the other hand, many faculties of education reported providing seminars and professional development training for teachers in programs for gifted learners or who want to upgrade additional qualifications in this area. Over 66% of institutions indicated that they offered activities such as conferences, summer institutes, invited speakers, seminars or credit qualifications for teaching certification in this specialty. Again, these programs were generally subsumed under special education diplomas and often reflect the direction of provincial policies in education. (It should be noted here that many of the provinces tie teacher salary levels to the number of advanced qualifications completed by a teacher, and special education is one of the general categories for this training opportunity.)

In summary, there is little education offered to prepare undergraduate teachers in the developmental and educational needs of high ability learners in Canada. What courses are available are optional, not required courses. This phenomenon seems to reflect society's reduced commitment to the needs of gifted learners and the pervasive philosophy of inclusive education for all. Some faculties of education offer excellent courses at the graduate level for educators interested in the field, however, no institution provides a major specialty.

Many institutions, as a response to demonstrated need from the educational community, provide advanced qualifications in education of gifted and talented learners. If a community of educators requests such professional upgrading, or the faculty of education provides leadership in developing such programs, then it appears educators avail themselves of the

opportunities. However, since no numbers of actual teachers enrolled in such advanced programs were solicited, it remains for further research to determine the interest and viability of professional development courses across the country.

It should be noted that two programs provide outstanding examples of professional development for teachers in Canada. McGill University in Montreal continues to offer its summer credit program for teachers of the gifted. A variety of teaching models are explored and applied with classes of gifted children for a number of weeks, exemplary role models teach and supervise instruction, and graduate credits are provided for teacher participants.

At the University of Calgary, along with teacher in-service sessions, a school outreach program is in place which teams master teachers with local classroom teachers in an on-site learning experience. Here university personnel go into the local schools when requested to train teachers, inform parents, and help administrators upgrade their skills in supporting the high ability learners in their communities.

It is evident from both these examples that universities can provide leading roles in the education of teachers of gifted and talented students. It remains for other universities to consider undertaking similar systematic programs based on the examples of these institutions.

### Conclusions

Education of gifted and talented children in Canada has seen major changes in the last ten years. Systemic reforms based on economic utility have led to cutbacks in personnel, and the number of students served in withdrawal or homogeneous classes for high ability students.

Provincial and Territorial Ministries of Education have individual approaches to serving the needs of gifted students. There is no clear evidence that indicates support for this group of students other than the mandates designed for special education policies. With the exception of Alberta, Ontario and New Brunswick, no provinces reported specific legislation beyond that of equal education opportunities for all students. When funding is available to local school boards, it comes under the aegis of special education and hence, allocation is left to the decisions of local authorities. Transportation of students, funding for programs, identification procedures, teacher certification, and program evaluation are the responsibilities of school boards which in turn receive little if any, specific funding from the Ministries of Education for gifted students. Ministries of Education need to evaluate their policies regarding education of gifted students and consider assuming a higher priority in this area.

Within the school boards on the other hand, school administrators are being asked to ensure that enrich-

ment programs are available to a wider student population. Regular classroom teachers are being required to provide more enrichment strategies within heterogeneous groups of students. There is little indication that vast numbers of school administrators or their teachers are receiving systematic professional development for the special needs of students identified as gifted learners. Hence, one questions that educational interventions are being consistently provided for these learners.

Although many school boards report providing funding for field studies, community mentorship programs and enrichment activities outside of the school building, limited numbers of gifted students are reported in homogeneous groupings, in withdrawal programs, and working with a resource teacher in middle and secondary schools. Because more and more classroom teachers are being asked to provide enrichment activities in the regular classroom, the onus is on the teacher to be flexible, creative and committed to serving the needs of the high ability students in her/his care. Opportunities for advanced placement and acceleration are reported available in many jurisdictions, however, these strategies are used with only a small number of students, particularly in the higher grades.

A number of school boards reported developing curricula and program guidelines for their teachers. Other jurisdictions reported supplying resource personnel with varying expertise to help classroom teachers with the needs of gifted students. Other areas reported excellent cooperation among teachers, parents and community members in providing transportation, expertise, and collaboration in enrichment activities for their gifted students.

Here is where the true creativity of our teachers stands out. There are islands of exciting programs being developed and implemented through the efforts of outstanding teachers across the country. Whether it is working with seniors to develop historical narratives, organizing community relief drives, communicating with international peers using computer interface systems, or planning experiments for use in our space programs, high ability students are being challenged by teachers who are committed to excellence for their students.

These are the same educators who take personal time to attend seminars and take additional qualifications courses to upgrade their teaching abilities. Because they care about gifted learners, they continue to learn how better to provide educational opportunities for them. Likewise school administrators, intent on ensuring the best learning for all, provide resources and support for their school faculty so that gifted students receive equal education just as do other exceptional students. Where gifted education thrives in Canada, we see a harmonious orchestration among administrators, teachers and parents. Greater sharing of these educational innovations should occur and celebration of

exemplary school programs needs greater attention across the country.

There is another section in this orchestra and that is the faculties of education. Clearly there is a need for a systematic appraisal of provisions to address the needs of gifted learners in both undergraduate and graduate programs. Universities could provide more required courses in the developmental and educational needs of high ability children so that all teachers would be introduced to this important population early in their careers. They could take leadership in research studies to evaluate policies and programs across the country. Studies such as those from the Ontario Institute for Studies in Education at the University of Toronto provide good examples of relevant research which can inform classroom practice. If faculties of education wish to remain players in the educational composition, they need to provide trained teachers for our gifted learners.

The results of this survey, though limited in numbers, represent a cross-section of Canada's educational communities. The very fact that so many educators took time to complete the questionnaires is a testament to their commitment to gifted education. During this period of change in educational circles, there is also an opportunity for renewal. Concerned educators and parents can take advantage of such reformations to advocate for educational commitment to gifted learners. There is expertise in Canada: it is imperative that we capitalize on this and make the educational welfare of our gifted students once again a high priority everywhere.

### **Summary**

The changing face of education in Canada has an impact on education of high ability students. In order to ascertain the current state of policies and programs for gifted students, a survey of provincial Ministries of Education, Faculties of Education and selected school boards across the country was undertaken. Results indicate that policies of inclusion are popular, diversity of program services is the norm, and regular classroom teachers, with some support from local school resource teams, carry the major responsibility for these students. Also, there is no consistent undergraduate or graduate credit training for teachers at faculties of education in the provinces. Advocacy by concerned educators and parents is an on-going need.

### **Acknowledgments**

Grateful appreciation is acknowledged for research support from the University of Ottawa and in particular, Maria Cuffaro, M. A., for her invaluable research assistance with the data collection and analysis. Lastly, my heartfelt thank you to all the educators at all levels across the country who took time to complete the questionnaires.

# Gifted Education in Europe: Programs, Practices, and Current Research

Roland S. Persson<sup>1</sup>, Helga Joswig<sup>2</sup> and Laszlo Balogh<sup>3</sup>

## Introduction

The fact that some individuals are capable of more than most others has been recognized in Europe for a considerable period of time. The philosophers of Ancient Greece, for example, bringing into the world the foundations of Science and Democracy, were generally respected, if not revered, by their disciples and the contemporary society (Grinder, 1985). They believed they were divinely inspired by *daemons*—tutelary spirits guiding and teaching them. Later, in the Roman Empire, the same notion was taken over, and such divine inspiration then became known as *genius* (or in Moslem mythology: a *jinni*); a word more familiar to modern proponents of Gifted Education.

There have been many illustrious Europeans following in the footsteps of, for example, Plato and Aristotle in terms of impacting with their brilliance, creativity and audacity—for good and for worse—the way Western history has unfolded, or at the very least, they have in their own unique way changed our understanding of history and society. Isaac Newton, Galileo Galilei, Vasco da Gama, Marco Polo, Martin Luther, Leonardo da Vinci, Karl Marx, Raol Wallenberg, Carl Friedrich Gauss, Wolfgang Amadeus Mozart, François Champollion, Carl von Linné, Sigmund Freud, Albert Einstein, Niccolò Macchiavelli, Marie Curie, Pablo Picasso, Lev Vygotsky, Niels Bohr, Ingmar Bergman and Winston Churchill are only a few from all over Europe, whose skills and insights have inspired—and occasionally threatened—the society of their time.

The fact that high ability potentially may pose a threat is to some extent a European dilemma too, which needs to be considered in outlining and understanding the status of Gifted Education and related research and

educational policies in Europe. While there are numerous exceptionally gifted and talented individuals in European history, most of them did not experience the reverence and respect awarded many a philosopher and thinker of Ancient Greece. Talent used for the well-being of a nation is a tremendous asset, but talent as a potential foe may well be a formidable threat, as European history shows well (cf. Persson, 1999).

The gifted European has been treated somewhat ambivalently over the years. There is in much of Europe a continuous, and mainly political, struggle between the ideals of elitism and egalitarianism, that has resolved very differently in the various nations of Europe. While differences between individuals in cognitive ability was regarded as something natural to the citizens of ancient Athens (Durazzo, 1997), such differences have become increasingly more contentious, and politically sensitive, since the time of Enlightenment in 18th century Europe. Above all, the legacy of Communist and Socialist tenets—as they pertain to education and individual differences—largely eliminated the significance of innate and genetically determined factors. In the former USSR, for example, and in countries then under Soviet influence, psychological tests were forbidden. They were regarded as instruments of class discrimination (Mönks, Katzko & van Boxtel, 1992; Urban & Sekowski, 1993 Heller & Hany, 1994).

Dorothee Wilms (1986), for example, Minister of Education and Science in the former Federal Republic of Germany, pointed out that, “detecting talent is not a selection process in the sense of social selection . . . Support of talent is an educational process and no social mechanism. Excellence is in principle independent of social rank” (p. 19). It is obvious that Wilms is endeavoring to negotiate a balance between opposing values in order to make Gifted Education politically possible. The ambivalence towards Gifted Education still looms large in Post-Communist Europe. On the one side, it seems, stand critics who equal talent

selection to creating a socially privileged societal stratum potentially beyond democratic principles. On the other side stand proponents arguing the democratic rights of all children to develop to their full potential. While both factions appeal to the importance of upholding democracy and the equal rights of citizens secured by it, they nevertheless base their arguments on very different aspects and understandings of the notion of equality. One faction argues the right to be *different* for the common good, in which case special provision for talent as well as for the learning disabled is seen as a necessity. The other faction, however, rather argues the right to be *similar*—also for the common good. But the result is that special provision for the highly able becomes controversial, since such children are often regarded as privileged by their ability. Hence, by a flawed conclusion—as is obvious by the research on genetic influence on cognitive ability presented elsewhere in this Handbook—they are often not regarded as in need of any special support. The aim for a proponent of similarity must therefore be to bring children of low ability up to a higher level, thereby offering them their democratic right to become ‘more similar’ (cf. Husén, 1979).

### **The Purpose and Structure of this Chapter**

For the sake of convenience, but also to some extent based on European nations’ understanding and implementation of Gifted Education, Europe may be divided largely into three areas: Northern Europe (including Scandinavia, The British Isles, The Baltic States, and Russia), Middle, Western and Southern Europe, and Eastern Europe (including The Balkans and The Ukraine). The outline of Gifted Education in 25 of the larger European nations follows this tripartite division, the purpose of which is to convey an overview of the status of Gifted Education in Europe in terms of existing policies, provision, relevant practices and specific research. The chapter is concluded with a summary, which also endeavors to answer the question whether there exists a typically European approach to high ability and its education and research.

The authors aimed at covering all European countries and not restrict the survey to the 15 nations of the European Union. Geographical Europe consists of some 40 nations inhabited by approximately 700 million people. For this purpose a standardized questionnaire was devised, which asked questions concerning the political recognition of high ability in the national school system and legislation, the history of Gifted Education in each country, the nature of specific provision offered for the highly able, and questions on the existence of special training for teachers. Also, in the event that a particular country has no legislation or any special provision, national representatives were asked to explain why this is not the case, to elaborate on their understanding of Gifted Education, and speculate whether it might eventually

develop. Furthermore, each respondent was specifically asked to name indigenous research on high ability and Gifted Education, if available, since the existence of such in any nation is a fair indicator of status and will be invaluable in focusing cultural differences in educational practice and policy.

The questionnaire was sent to Embassies, Ministries of Education and Science or bodies and agencies sorting under these, and to national experts known by the authors. Considering the often contentious nature of Gifted Education in Europe we wished to provide national authorities with an opportunity to respond and outline their reasons for acting in favor of the highly able in their school systems or, as in some cases, the reason behind their lack of action and interest. In particular, the national correspondents of the European Council for High Ability were reliable sources of current information—scientific when available, and their own personal experience and observations when required. The contribution of personal experiences is a particular concern to the outline of Gifted Education in Eastern Europe, The Balkans, and The Ukraine, since the amount of published material so far is limited—and more so in some countries than in others.

Information was received pertaining to 25 European countries, thus excluding 15. The reason for exclusion was generally due to lack of response from authorities and/or individuals contacted. However, the number of respondents is more than sufficient, and representative, in order to convey the status and nature of Gifted Education and relevant research in Europe reliably.

### **Eastern Europe and the Balkans**

Bulgaria, Croatia, Hungary, Poland, Romania, Slovakia, Slovenia, and the Ukraine generally recognize high ability through legislation—most commonly through the national Act of Education—which regulates how the issue of high ability is dealt with. The manner in which Gifted Education is managed, however, is broad. Some prescribe provision for talents as obligatory for state organizations (e.g. ministries, public schools and so on). Others only mention it for calling the issue to attention. Note that such legislation has mainly developed in the 1990s, reflecting directly the programs of political change of the Post-Communist Era. However, the fact that educational efforts now are made, and even thrive, can be traced back to the Communist period in each individual country. In spite of the imposed egalitarian dogma, most of these countries already had a tradition of nurturing high ability in special classes, workshops and courses, predating Communism. These efforts were often tolerated and endorsed by the authorities, but on the condition that talents were made ‘ambassadors’ to promote the ideals of the Communist State internationally. Such provision, however, was not always pursued with the welfare of the talented individuals in mind, which has been very painfully revealed, particularly in the former German

Democratic Republic, where researchers have now been given access to previously classified archives (e.g. Berendonck, 1993). The pursuits focused during this era were traditionally Sports, the Arts, and the Sciences. The knowledge and experience acquired regarding the nurture of talent, albeit under dubious political circumstances, were influential far beyond Eastern Europe. Particularly models pertaining to talent detection and development in Sports (Régner, Salmela & Russell, 1993), Musical Performance (Neuhaus, 1969), and Music Education (Kabalevsky, 1988) became internationally recognized and often adopted or adapted elsewhere.

With a new political agenda, founded on democracy, this long-standing experience of nurturing talent facilitates the further development of Gifted Education in this area of Europe. Significant developments have already been made during the Post Communist Era. Also, with the continued development of specialized educational practices, indigenous research has followed and improved, since research and findings are now communicated freely across national borders. For example, researchers and educators in several Eastern European countries have joined the European Council for High Ability (ECHA) as well as the World Council for Gifted and Talented Children (WCGTC). They participate actively for the exchange of experience and the dissemination of research findings.

However, the current political agenda is recent and the aftermath of the previous era are still obvious. One of the greatest obstacles for further improvement and development is limited financial means, which is reflected in, for example, the current lack of systematic special training for teachers in Gifted Education, as well as the lack of scope in these efforts. In spite of difficulties progress has been quite remarkable in a relatively short period of time. Given that this trend is maintained, it is only a matter of time before the current differences in research quality, effectiveness and educational provision for the highly able between Eastern and Western Europe are leveled out.

#### *Bulgaria*

Article no. 43 of the Bulgarian Code of Education states the responsibility of the Ministry of Education and Science to identify high ability and provide for its subsequent educational provision. However, during the 1990s significant changes have taken place, and the State is no longer sole provider. There have emerged several foundations, non-state organizations and a number of new programs, all of which have been organized to cater to the highly able. The St. Cyril and St. Methodius International Foundation, for example, plays a significant and active role in educating young talented individuals by means of vocational training and career planning. The *Reference Book of Non-Governmental Organizations* (1997), published by the Bulgarian Foundations and Associations Union, lists

more than 20 non-governmental organizations, that have the nurturing of talent as well as specific teacher and parental training as their expressed aim.

Of particular interest are the Bulgarian special schools devoted to the Arts, Mathematics, the Sciences and Languages. Some of these were already founded in the 1960s, but with a changed political climate, they have increased in numbers. Such schools tend to provide a greater number of study hours and a greater variety in the subject on which such a school specializes. Regular schools also make provision for gifted students. They offer special classes in Mathematics, Informatics, the Sciences and Languages. In addition, after the seventh school year, children also have a choice of certain optional subjects extending and enriching the general curriculum, thus matching a child's specific interests more effectively. Bulgarian educational expertise is aware of the need to provide a rich and stimulating learning environment for optimal development, which is indeed reflected in a number of recent studies (Jakova, 1993; Stoycheva, 1994, 1996; Trifonova, 1994; Stoyanova, 1995; Kaftandjieva, 1996; Milanova-Kamburova, 1996).

Competitions are regularly held for able children on local, regional, national, and international levels. Winning such competitions generally entails gaining admission to universities or to prestigious Arts or Sports Academies. Award winners of international competitions, on the other hand, receive more public attention and are often recognized by the media. In addition to available competitions for students there is the St. Cyril and St. Methodius International Foundation Awards for teachers of Mathematics, Chemistry, and Biology, in recognition of their outstanding contribution to the identification and encouragement of young talents.

In the wake of Post-Communist societal changes regular schools, as a whole, are now more alert to talented students, and the development towards even greater awareness seems to continue. There are several programs worked out by individual teachers, or teams of teachers, who often establish educational centers with a specialized focus. This is done to some extent in response to a series of international seminars organized by the Ministry of Education and Science between 1979 and 1989, on modern trends in Education—with special focus on giftedness and creativity. This effort alone has stimulated more than 30 schools to launch special programs for educating gifted students. Furthermore, between 1982 and 1987 Edward De Bono's methods for teaching thinking skills were adapted in many schools under the auspices of the Ministry of Education and Science.

In addition, there are currently a variety of extra-curricular programs for highly able children available, such as clubs, summer camps, summer schools, festivals, shows, and exhibitions. There is no official mentorship program for teachers focusing on the

highly able, but teachers tend to cooperate in matters of Gifted Education. Basic teacher training, as yet, does not include a systematic preparation for the nurturing of special talent, though student teachers are given some relevant, albeit basic, information. Note, however, that there exist graduate programs at universities focusing on high ability (cf. Jakova, 1996).

### *Croatia*

High ability is also recognized by the Croatian Government, but action for special provision is taken mainly at preschool and primary school levels. A national preschool program with such a focus is endorsed. Gifted Education at primary level is regulated by the Code of Practice for Gifted Students from 1991, and addresses issues like different domains of giftedness, identification methods, programs for enhancing and nurturing giftedness, as well as evaluation models (Koren, 1994).

The current state of Gifted Education in Croatia has, to some extent, roots in former Yugoslavia, at which time most of the activities were coordinated and supervised by the Ministry of Employment and its agencies (i.e. State Employment Offices and Vocational Services). The most important fields of study and learning in which development of Gifted Educational practice is currently taking place are the Fine Arts, Mathematics, the Sciences, and Sports (Arambasic, 1996; Vizek-Vidovic, 1996). Able students in Croatia attend extracurricular classes—within the regular school setting—that are specially organized in these fields of interest. This type of provision exists in several different varieties (Sekulic-Majurec, 1993, 1996; Vizek & Vlahovic, 1993; Vlahovic-Stetic, 1993; Cvetkovic, George, Sekulic-Majavec et al., 1996; Kolesaric & Koren, 1996).

There are several special summer schools and courses for talented students in Mathematics, the Fine Arts, Literature, and Astronomy, lasting from one to two weeks at a time. Also, a mentorship system exists at secondary school level, in which some teachers from the general school staff are specially appointed as 'mentors' to especially prepare able students for national and international competitions. Competitions, as a means of Gifted Education, are highly valued particularly in primary schools. They are organized in all subjects and are highly respected, since a victory will mean receiving scholarships for grammar schools or universities. There is no special program in Croatia for training teachers specifically in Gifted Education, however, but the topic is sometimes addressed by further training programs for teachers.

While high ability is indeed recognized by the Croatian Government, there is currently a lack of funding, administrative support, and adequately specialized teacher training. There are some private

initiatives promoting Gifted Education such as, for example, Smarties—a parental association organizing special preschool activities for fostering children's creativity and ability. For talented individuals in the Performing Arts there exist drama centers for youth. And in 1998 the Croatian Psychological Association uniquely established a special division within its framework dedicated to the promotion of giftedness.

### *Hungary*

Hungary also recognizes the necessity of nurturing talent and emphasizes its significance for the future wellbeing of the nation by establishing a legislation to govern the educational provision regarding the highly able. The Public Education Act of 1993, The Higher Education Act of 1995, and Regulations for the Development of Public Education of 1996, are all examples of current—and recent—legislation securing the continued development of Gifted Education in Hungary. Consequently, with such legislative support, Gifted Education is making significant strides forward in the new political climate.

To cater to, and provide for, talents, however, is not new in Hungarian educational history. To some extent, this continued development under new circumstances is based on already existing traditions. Interest in nurturing talent specifically was evident already in the early years of the twentieth century. Teachers, as well as researchers, have paid particular attention to the development of giftedness—although not always explicitly—since the time of World War II.

In addition to the Hungarian system of public schools, private schools and schools maintained by churches and foundations, have also participated in developing practices.

The current frameworks for nurturing talent were established already prior to 1980, and entail special groups, workshops and special classes. These three are common in schools at both primary and secondary levels. The most successful special fields include the Arts, Mathematics, the Sciences, and Sports (Laczó, 1993; Majoros, 1993; Harsányi, 1996; Kárpáti, 1996; Süle, 1996; Pásku, Kerekes & Fekete, 1997). Since the late 1980s, however, so-called complex programs have been implemented. These aim not only to develop skills and abilities, but also take into account the personal background of the individual student (Balogh & Nagy, 1991, 1995; Czeizel, 1995; Oppelt, 1995; Balla, Hanoi & Molnárné, 1996; Balogh, Dávid, Nagy & Tóth, 1997). Basic Art schools (teaching Fine Arts, Music, Dance and so on) traditionally hold a special position in Hungarian Gifted Education. Talent in Sports is provided for by special classes in primary schools and in region-based Sports Schools. High ability is also advanced by the existence of Special Colleges.

The tutorial system is increasingly becoming an established form of supporting gifted students. Professors and outstanding researchers allow secondary students to participate in research work. This type of activity is organized by the larger universities.

Competitions are also a means for promoting talent in Hungary. The school system has promoted local, regional and national competitions for a long period of time. One of the most significant is the National Academic Competition of Secondary Schools, where winners are awarded admission to the universities. The number of competitions for primary schools is increasing.

Higher education is currently experiencing a return to Faculty Colleges, which are tertiary institutions gathering the most able among students in certain academic fields; providing them with special programs to facilitate their continued development and training (Pásku & Imre, 1993).

The dynamic development of Gifted Education in Hungary in the last decade is reflected in indigenous research work too. Specific research is increasingly being published all over the country at universities, colleges and research institutions and is being disseminated at international conferences. Such publications on Gifted Education, specific to Hungary, are helpful points of reference for a continued effective advancement (Gefferth & Herskovits, 1991; Herskovits & Gyarmathy, 1995; Bóta, 1996; Dávid, Pásku & Vitális, 1996).

The success so far has been accompanied by an increasing focus on high ability in in-service training for teachers, the culmination of which prompted the Kossuth Lajos University at Debrecen to launch a Teacher of Gifted Education Program in 1997/1998. This program is a four-semester, graduate, in-service training, comprising more than 600 hours worth of study. It is based on the syllabus required by the University of Nijmegen, The Netherlands, to gain The European Advanced Diploma in Education the Gifted (often termed the ECHA Diploma). Note that special training of parents is also becoming increasingly common in Hungary (cf. Györik, 1993; Herskovits, 1994; Varga & Gyarmathy, 1996; Dávid & Balogh, 1997).

In addition to the public and general system of education, other public institutions also take part in providing for talent students (i.e. centers for culture, community centers and so on). There are organizations that endorse the promotion of talent, fully, or as part of their agenda. A few of the more important ones are The Hungarian Association for High Ability, The Corporation for Public Academic Activities, The Bolyai Association, MENSA, The Hungarian Association for Professional Training, and so on. The number of foundations fostering the development of giftedness is increasing and the establishing of regional Giftedness Centers is in progress. These are intended to facilitate

identification procedures and host special educational programs. The first center has already opened in Budapest.

#### *Poland*

The first move towards legislating Gifted Education in Poland took place in 1991. That is not to say, however, that Gifted Education was non-existent prior to this. Some educational provision was available, but it was neither comprehensive nor particularly well organized. Presently, enforced by the new legislation, Gifted Education is recognized by the Polish authorities, and all three educational levels are considered: primary, secondary, and tertiary.

In programs aimed at developing appropriate educational practices, talent in Music, Mathematics, and Visual Talent are given priority (Kepinska-Welbel, 1991; Limont, 1993a, b; Klimas-Kuchtowa, 1996; Manturzevska, 1996). In these fields, specific provision begins already in primary school. Children have, for example, special Ballet and Sports classes. In secondary education Music, Ballet, the Fine Arts, the Social Sciences, and Mathematics become focus. Highly able students tend to have special classes after school, but The Polish Children Fund (PCF) also organizes special summer schools and courses. However, these usually focus on the Arts. PCF additionally provides special meetings and workshops on Modern Languages, History, Astronomy, Physics, and so on, in which talented students are given the opportunity to meet with adult experts in their fields of interest. PCF is also in charge of organizing mentorship programs.

The current system is appealing to children, and is effective. Students in primary schools may exchange one or two classes, whereas students in secondary schools, simultaneously with their studies in school, may also attend university courses.

Competitions are numerous and varied in Poland. For example, there are 24 competitions available in the Arts, Astronomy, Biology, Chemistry, Philosophy, Physics, Geography, History, Information Technology, Modern Languages (e.g. English, Beylo Russian, French, Latin, German, Russian, and Polish), Mathematics, Ecology, Economy, Technology, Polish Studies, Universal History, Law, Agriculture, and Nursing. Some of these contests are held both for primary and secondary school children. Others are organized for secondary schools only. The winners of primary school competitions will gain free admission to secondary schools, and the winners of secondary school competitions obtain several priorities when applying to study at university.

There is no special training of Polish teachers in Gifted Education, however, but high ability is often discussed as part of Further Education Programs. There are programs for parents, some of which aim at shaping parents' attitudes to better be able to provide a creativity-inducing environment (Ledzinska, 1993,

1996; Mendeka, 1996a; Niebrzydowski & Poraj, 1996; Swietochowski & Poraj, 1996). Note that research in the field of giftedness and Gifted Education is considered important in Poland, and creativity appears to be a field of study of particular interest (Strelau, 1992; Limont, 1995; Sekowski, 1995; Mendeka, 1996b; Necka, 1996; Niebrzydowski & Poraj, 1996).

### *Romania*

Romania follows the legislative trend of the rest of former Communist Europe. The latest Act of Education was passed in 1995, and endorses the recognition of gifted education at primary, secondary, and university level. It includes aspects such as educational acceleration, creating special classes, identification criteria, provision requirements, the special conditions for admission to universities, and special resources needed for Gifted Education. Note that the Romanian authorities are still at the early stages of implementing this new legislation. One problem currently posing an obstacle to making it effective is organizational in nature; there is lacking a department within the Ministry of Education that could specifically coordinate and organize all matters pertaining to Gifted Education.

Similar to Hungary, the traditions of nurturing talent predate Communism. Educational legislation, from as early as 1904 and 1939, recognizes giftedness as a special and separate issue. Following World War II, however, the sole provision for highly able children was made in placing them in special classes.

Current strategy gives priority to special provision in The Arts (Music and Folklore), Sports, Informatics, Mathematics, Physics, and Biology. New areas for provision are Communication Skills, Leadership, and Creativity. There are special schools for the Arts and Sports in most larger cities, and there exists an abundance of secondary schools with special provision in Informatics, Modern Languages, Mathematics, Physics, and the Sciences. Regular schools do not often consider differentiation; a common problem is the difficulty for teachers to actually apply educational theory in practice. Note that training programs in Pedagogy and Psychology were banned at universities from 1970 to 1990.

Summer courses are common in Romania; not only as staged by the Ministry of Education, but also by private organizations. One of these organizations: RO-Talent, has a leading position; but there is also the Henry Coanda Foundation and others. Competitions regularly take place for pupils from their fifth school year and on, in their local school, at regional, and national levels. Particularly able children also participate in international contests. The awards are attractive: winners are awarded with foreign travel and admission to universities. Unfortunately, these competitions often lack an appropriate pedagogical basis, but the need to

carry out such activities on a sound basis is increasingly understood and considered (Cretu, 1992, 1993, 1996; Lazar, 1993).

Student teachers currently obtain some introductory courses in Psychology and Pedagogy relevant to high ability provision. Iasi University, for example, offers a course in Gifted Education, which is obligatory for student teachers. But whether Gifted Education is part of teachers' further education training or not, depends on the policies of each of the Local Education Authorities, which are mainly organized by the 'Casa Corpului Didactic'.

In sum, while high ability is certainly a focus of Romanian educational policy, its implementation is often missing. The main reasons for this are lack of professional knowledge and information, no priority in funding, a shortage of expertise in Gifted Education, and the need for specific administration of these matters at ministry level. There are some new developments in Romania in spite of difficulties, however, which bode well for the future. There is indigenous research in progress (e.g. at the Institute of Educational Sciences at Bucharest and its centers throughout Romania), and an additional program for teachers in Gifted Education at Iasi University is being launched. Also, there have been several doctoral dissertations produced focusing different aspects of Gifted Education from the universities at Iasi, Bucharest, and Cluj-Napoca.

### *Slovakia*

Legislation relevant to Gifted Education in Slovakia is derived from the legislation of former Czechoslovakia. Beyond general guidelines, however, suggestions as how to operationalize these guidelines are presently absent. Provision for talented children is available but mainly at primary and secondary school levels.

Preceding contemporary Gifted Education in Slovakia were so-called People's Art Schools, which were established following World War II. During the 1960s a system of special classes with enrichment in a few particular subjects—still in operation—was conceived, and implemented. However, after 1989, and the break with Communism, the system has also been implemented in private schools. Special teaching in Music, Dance, Visual Art, Literature, and Drama is available in so-called Basic Art Schools, which are spread throughout the country; about 10% of all children attend these schools. In addition, there are several Music Conservatoires and Industrial Art Schools at secondary level available. Children with special abilities in Sports attend Sports Schools (Dockal, 1996; Kovac, 1996). Children highly able in Mathematics may attend special Mathematics classes from their fifth school year, or may proceed to study at independent secondary schools specializing in Mathematics (Laznibatova, 1993). Earlier, special classes in Foreign Languages were available from the fourth school year, but with the

changed political climate, every school now teaches Foreign Languages. Particularly able children may therefore start learning new languages as early as from their first year of school (Farkasova, 1993).

Since 1989 a system of eight-year grammar schools has been established (succeeding the fourth year of primary school) for highly able children, where teachers provide advanced training aiming at high-level proficiency in every taught subject (Dockal, Lazibatova & Kovac, 1992; Dockal & Kovac, 1993; Farkasova, 1993; Kovac & Matejik, 1993; Lazibatova, 1993; Ostatnikova & Dohnanyiova, 1996). There are no special programs for gifted children in regular schools, however, but grade skipping is practiced promoting particularly able children ahead of normal grade placement, or allowing promotion in particular subjects only.

Several competitions are organized for able pupils on regional, national, and international levels in the Arts and Sports. Teachers have the opportunity to attend further education with a focus on Gifted Education, but there is currently no special teacher training available.

In addition to schools, different professional associations take a special interest in able children. One of the most active is the Slovak Association of Mathematicians and Physicists, which organizes competitions and summer camps; such camps are also similarly organized by the different Arts Associations (i.e. Fine Arts and Music). The Czecho-Slovakian Association for Gifted Children was founded in 1991, and its members are actively involved in specific research and/or education. The Association arranges conferences, seminars for parents and teachers, and summer camps focussing on creativity involving both the able children and their parents.

#### *Slovenia*

The needs of gifted children in Slovenia attract much less attention than do the needs of children with learning disabilities. State institutions are less active in Gifted Education than they are in traditional Special Education, which tend to emphasize various disabilities. The result of current priorities is that financial means to pursue Gifted Education are relatively scarce; however, private initiatives have increased substantially. Private resources are available and private institutions make available scholarships, talent education, and schools for the highly able.

Interest in safeguarding the continued development of gifted individuals, however—just as in most other Eastern European and Balkan nations—has a long-standing tradition. Special provision for talent has been given attention for almost two centuries. However, to better and more effectively operationalize and implement legislation relevant to Gifted Education, systematic efforts are now being made to establish a

Ministry of School and Sports which, when fully functioning, will also coordinate provision for the highly able in Slovenia.

Gifted Education in Slovenia emphasizes the need for differentiated curricula and training programs in the different domains of talent: Sports, Music, Arts, Drama, and so on (Ferberzer, 1993, 1996; Makarovic, 1993, 1996; David, 1997).

Post-Communist Slovenia is developing towards educational pluralism, which entails the possibility of choice at each educational level, and in each direction, as well as emphasizing the autonomy of the individual students. Schools are being made more independent from government authorities; also, international comparisons with other educational systems are made, and competitions are held; furthermore, it is now possible to study abroad, and the funding of scholarships for gifted children has increased. Teacher training has become more focused on Gifted Education; while teachers tend to learn the theory, however, they often fail to apply theory in practice.

In spite of some success in developing Gifted Education, full recognition is still wanting. To some extent, this may be explained by prejudices (in terms of the legacy of previous political ideologies), financial difficulties, lack of theoretical knowledge and expertise, insufficient teacher training, lack of scholarships, insufficient recognition of initiatives, and the fact that there is currently no national organization with an expressed interest in the promotion and education of highly able children. However, in the past ten years there have been several conferences addressing Gifted Education and related issues, for example, Gifted Children in the Educational Process at Maribor in 1987, Extra-Curricular Activities in Primary Schools, also at Maribor in 1988, and Gifted Children: Their Situation, Problems and Possibilities of Development at Novo Mesto in 1994.

A need for developing Gifted Education more comprehensively has been brought to the attention of the Slovenian authorities several times. It is important for future and continued development, however, that it be sensitive to Slovenian culture and traditions.

#### *The Ukraine*

Provision for the highly able in the Ukraine has been an issue in Education since the 1930s; it largely failed to develop due to the Communist egalitarian ideology. Specific research into the field began in the 1950s, but governmental recognition of such research did not arrive until the 1980s. Research in the field is currently being pursued at, for example, L'viv State University, where a project has been launched focusing on the development of intellectual and social talent in non-traditional educational programs, as well as on the impact of family education on high ability. Of interest

to this research project are also methods of identification (Partyko, 1996).

The change in policy and attitude to Gifted Education in Post-Communist Romania is largely due to a political desire to make the Ukraine comparable with most other nations in the world. It is now 'fashionable' to address issues of Gifted Education, and recognizing young talents is believed to improve the Ukraine's standing in the global community.

The Ukrainian Government's actions officially demonstrate that Gifted Education is indeed recognized in primary education and in secondary education; Gifted Education pertaining to higher education, however, is currently not similarly recognized. Priority is given to Sports, Music, Visual Arts, Dance, the Sciences and Verbal Skills (i.e. talented poets and writers). There is some attention given to provision for talented individuals in Business and Management, which is a field of talent gaining increasingly more interest.

Educational provision is mainly focussing the development of cognitive abilities (Kholodnaja, 1993; Borodchuk, 1996; Partyko, 1996; Shavinina, 1996a), but the need for addressing creativity is also recognized and promoted by some researchers (Shavinina, 1996b).

In the Ukraine there are special schools and studios for Music, Painting, and Dance; children talented in the Sciences are provided for in grammar schools. Able students in the mixed-ability environment of regular schools are occasionally given individual assignments. This type of provision is fickle, however, and always dependent on teachers' sole initiatives, and is therefore not common. There exists an experimental program called The Development of Creative Giftedness and summer schools organized by the so-called Minor Academy of the Sciences (Kokotko, 1996). Other available programs involve particularly gifted youth from the rural areas of the Ukraine; competitions are held in each of the prioritized subjects at school level, regional level, and national level; the national level competition is usually followed by an International Olympiad. Note that Ukrainian teachers generally are trained on how best to prepare able children and adolescents to take part in the competitions on offer; one means of preparation is to gather candidates in special classes.

In addition to provision within the national school system, there are several specially appointed Counselors in the Ukraine, acting as moral support to the gifted and the talented, are available for consultations; such consultations are always free of charge.

### Western, Middle and Southern Europe

State ordinances and laws guiding education in Austria, Belgium, France, Germany, Italy, Portugal, Switzerland, Spain, and The Netherlands tend to be *inclusive*. That is, ideally all education should be integrated within the regular school system (cf. Daunt, 1995;

Mitchell, 1995), as recommended by the UNESCO World Conference on Special Needs Education: Access and Quality, at Salamanca, Spain, in 1994. Legislation, therefore, often contains general formulations on the rights of all children to receive education and states that such education should adequately support, and meet, their abilities and interests; such formulations also imply the possibility of making provision for highly able students. In some legislation there is also emphasis on accelerated and enrichment programs, which could be interpreted as recognizing Gifted Education. However, the acceleration possibilities formulated in these legislative frameworks refer mainly to early admission to schools, grade skipping or moving through grades at a faster rate than normal. Acceleration activities such as these are not accepted practice in all Western, Middle, and Southern European nations; prejudice and bureaucracy often complicate their implementation.

With regard to enrichment as a means of providing for highly able students, European school documentation contains, and suggests, different forms of expanding and deepening knowledge and skills, which is also relevant to Gifted Education, and therefore supportive of gifted children. Such suggestions are based on various forms of 'inner' and 'outer' differentiation.

*Inner differentiation* is carried out by conveying different and additional subject matter to the existing curriculum, as well as employing special teaching methods—especially project-oriented and multi-subject based learning. Allowing students to develop at their own pace, and making use of their own unique knowledge and experience, obtained prior to entering a certain school year, are important aspects of this strategy (Hany, 1995). However, taking such individual components into consideration in groups, where students have been matched with regard to their level of achievement, has proven to be somewhat problematic. There is no single specific method available for teaching the highly able. The countries discussed here are all working at different levels of intensity in establishing curricula for specifically supporting and promoting gifted students (Pagnin, 1994; Hany, 1995; Heller, 1995, 1996; Cardoso, Coutinho & Fernandes, 1997; Martins, 1997; Joswig, 1998; Tournon, Iriarte, Reparaz & Peralta, 1998).

The possibilities of *outer differentiation* are also discussed in European educational documentation. General guidelines do exist, which may be operationalized and allow further development; these refer to differentiation in school systems and to special courses in different types of schools and institutions.

#### Austria

The Austrian school system is supportive of the needs of the gifted in that it differentiates between general and professional education, between electives, and

optional and elective subjects. It also allows flexibility in core and extension subjects, and accepts autonomy by means of, for example, allowing schools to choose a certain profile and become a 'special school'. Paragraph no. 17 of the Austrian 'Schulunterrichtsgesetz' (Code of School Teaching) requires that every pupil be instructed according to his or her natural ability as far as this is possible; in this legislation there are defined possibilities for acceleration and enrichment.

The Austrian school system commences with four years of primary education ('Grundschule'). It then divides into two tracks, namely the main track school ('Hauptschule', which has four levels), followed either by polytechnical training (leading to a vocation) or by attending a so-called 'extension school'. The General Upper School (which has eight school levels) follows primary education and concludes with the 'Matura' diploma.

One of the main tasks of Austrian school policy during the last twenty years or so, has been to create a system, which was flexible—vertically as well as horizontally. It is therefore now possible to enroll a child earlier in the first grade, if parents wish it and if the principal agrees that this is a feasible strategy. It is also possible to switch between the two school tracks (Bundeskanzleramt, 1994). Paragraph no. 26 of the 'Schulunterrichtsgesetz' allows for skipping grades once in the 'Grundschule' (pupils 6 to 10 years of age), again between the Grundschule and the eighth grade (pupils 10 to 14 years of age), and also after the eighth grade (pupils 14 to 18 or 19 years of age). It is also possible to sit for the 'Matura' at age 15.

In addition to these options, the Austrian legislation differentiates between achievement groups, and there exist numerous forms of outer differentiation relevant to gifted education. Partial learning at higher-grade levels, for example, is possible. Furthermore, there are the so-called Plus Courses in Salzburg, in Oberpullendorf, and in Tirol.

Some of the main track schools and the general secondary schools host special forms, which emphasize Music, Sports, or Modern Languages. In Vienna, for example, there is an experimental primary school ('Die bilinguale Volksschule'), where German and English are used as the languages of instruction. Similar schools exist in Graz and Linz. There is also The Vienna International School, where children are taught from age five and on to the International Baccalaureate (cf. Bundeskanzleramt, 1994). It should also be noted that Austria has six Colleges of the Arts. The first school specially designated to the highly able—the Sir Karl Popper School—was launched in 1998, with two classes at secondary level, based at the Wiedner Gymnasium in Vienna. There are plans to expand this school progressively and also include primary education. It is the explicit aim of this school to support particularly gifted individuals in different

intellectual and social domains; the curriculum has been developed by the Popper Club, and one of the characteristics of the school is the use of a coaching system (cf. Witzmann, 1998).

Yet another method of outer differentiation in Austria is the possibility to attend university courses for particularly talented individuals. The 'Landschulräte' (the state school boards) of Salzburg and Tirol, as well as the 'Stadtschulrat' (municipal school board) of Vienna, have several agreements of cooperation with the Universities of Salzburg and Innsbruck, the 'Mozarteum' Conservatory of music, and the Technical University of Vienna (cf. <http://www.bmuvie.gv.at/pbegabung/>). In addition, so-called home schooling is allowed in Austria as long as it is pursued under state control.

In regard to inner differentiation, the 'Schulunterrichtsgesetz' provides for differentiation of course content and teaching methods for pupils of different achievement levels, who are being taught together. There are currently experimental pilot schools, and in five of the federal states—at a higher-education level—there are also pilot courses relating to the curricular coursework, as offered by the European Council for High Ability (ECHA) in conjunction with the University of Nijmegen in the Netherlands. A three-part basic teacher training course, leading toward the European Advanced Diploma in Educating the Gifted, is available for teachers interested in gifted education.

Pupils at all school levels may put their talent to the test in annual competitions in Modern Languages and in the Social Sciences, such as 'Europa macht Schule' (i.e. Europe goes to school) or 'Jugend Innovativ' (i.e. The innovative young). They may also compete in Sports (in tournaments and championships), the Arts (e.g. Prima La Musica), as well as in the Olympics for Mathematics, Physics, Chemistry, and Computer Sciences. The Federal Ministry for Teaching and Culture is currently planning an evaluative study to examine the long-term effects of such contests on the personality development of students who participate in these events. A special effort to support gifted education are the annual summer academies offered in some states and the initiatives of a parent group (i.e. Austrian Club for highly talented children), which was founded in 1994 and now has chapters in six of the Austrian states.

In conclusion, it is clear from all the current initiatives and activities in Austria, that supporting the gifted and talented is increasingly becoming more and more important both from the perspective of Austrian authorities but also from the perspective of society as a whole.

### *Belgium*

Belgium is a federal state with three communities (the Flemish, the French, and the German community), and

two regions: Flanders and Wallonia. Both regions are autonomous and have separate educational legislation. In neither region, however, is giftedness recognized; at least not by the same token as special provision for the physically handicapped children or for children with severe learning difficulties is. In Flanders and Wallonia there are well developed, but separate, systems of special education also, divided into eight domains; however, neither of these special educational systems include a domain targeting gifted children.

While highly able children are not recognized as a specific target group, gifted children may nevertheless benefit from the more general measures taken toward this end on kindergarden and primary education levels made possible by a recent policy focusing 'extended care'. This policy aims at enhancing the abilities of schools and teachers to deal with differentiation in a more efficient way. Gifted children can certainly benefit from this novel educational approach in spite of the fact that its main target group are children other than the highly able. This special program was launched in 1993, as it became clear that too many children were not appropriately benefiting from the general way of teaching in mainstream primary schools.

However, there are at present no specific efforts made by the Ministries of Education to provide for gifted children. On the other hand, private schools, five secondary Arts Schools and three secondary Sports Schools, have been established in Flanders to cater to the highly able. But for all other gifted students, special provisions are supplied only in the regular classroom. The measures usually taken to aid highly able children in the regular school involve grade skipping, early school admittance, part-time attendance in a higher class, special support provided by a peripatetic teacher, mixed-age classes (especially in small schools), projects for the gifted, informal differentiation, autonomous study, and homogeneous classes (streaming). During holidays, private organizers provide courses in Modern Languages, Sports, Creative Writing, and Computing for gifted and motivated students aged 12 and older. There are also annual Belgian Olympics in Mathematics, Physics, Chemistry, Biology, and Modern Languages for students in their final year of the secondary school.

There is currently no special teacher training targeting the education of talented children and adolescents, but there are two-day seminars available to teachers on "Differentiated curriculum in primary and secondary education," which has been on offer since 1995 (Kieboom, 1994). Also, the Belgian Association for Gifted Children and Adolescents (Begaafde Kinderen en Adolescenten—BEKINA), founded in 1986, takes a leading role in providing information and raising the general awareness in Belgium of the necessity and significance of providing suitable education also for gifted students.

### France

The notion of high ability/giftedness has so far been somewhat inconsistently recognized in France. While recognized by the government as an issue in primary and secondary education, there has as yet been no special policy implemented. The French school system is organized around the 'Lycées', which are schools focusing on the Social and Natural Sciences, and Economy, followed by a two-year preparatory period, which may lead to admission to elite schools—the so-called 'Grande Ecoles'. These different school systems are usually seen by the authorities as sufficient in also meeting the special needs of gifted students.

However, special efforts to promote gifted children do exist; for example, early school admittance is possible. There is no longer a standard minimum age for when to enroll in the school system, nor is special approval needed from the Local Education Authority; approval for admission is given by the school in which the child is to be enrolled. So-called home schooling under state control is also possible, and grade skipping is an option. A student may skip one grade when in primary school, and in the 'collège' (which students enter at age 12) there is in addition the possibility of shortening the four-year program to three years. This means that, given special permission, the examination concluding secondary school may be obtained before the age of 17.

There are also a number of private schools in France, accepting students mainly on the basis of their achievement. Such schools, additionally, often consider parental financial status when deciding whether or not a student should be admitted; in other words, tuition is expensive and such schools are therefore open only to the socially privileged. There is only one amongst the private schools—the Lycée Michalet at Nice—hosting approximately 150 students, that is entirely devoted to intellectually talented students (from ages eight to 16). But there are 13 of the colleges that provide special courses for intellectually talented students between the ages of 11 to 15. The first such special course was launched in 1990 at Collège du Cèdre, in Le Vésinet, near Paris, which is a state school. Since the 1970s, however, there have existed special schools in every region of France for talents in Music and Sports; the most famous of these is Ecole de L'Opera at Paris.

A number of competitions are organized regularly in France, including sports tournaments and competitions in chess and music. Most such competitions are broadcast on TV or Radio. In addition, a variety of French associations organize scientific or mathematical games such as 'Les Olympiades de Chimie et de Physique', or Mathematics competitions like 'Kangourou' and 'Logic Flip'. One Parisian university (Jussieu) regularly organizes courses and meetings to specifically challenge teenagers from different fields of

pursuit. Once a year they gather young scientists from all over France to the Mathematics and Jeans Congress. The 'Ministère de l'Éducation Nationale' also organizes competitions in subjects such as French, Philosophy, Mathematics, English, German, and Physics for the most outstanding students in the 'Terminales' (i.e. the examinations concluding secondary education) at the end of the school year (Monnier, 1998).

A very active organization in France, aiming at promoting giftedness and talent, is the 'Association Française pour les Enfants Précoces (AFPE)'. It aims ultimately at changing the French school system in a way beneficial to gifted children, but also to continue to provide special training for teachers, advising parents of gifted children, as well as organizing meetings and conferences where scientists, teachers, and parents meet and discuss the different aspects of supporting and nurturing gifted and talented individuals (Côte, 1996; Côte, Adda, & Capron, 1997; Côte, Adda & Cancill, 1998; Côte, Bouchard & Delcros, 1998).

#### *Germany*

Germany is a federal republic with control of education resting with the individual states; legislation stipulates that each young person is to be provided with an education regardless of his or her heritage or economic situation. Furthermore, education must reflect the child's talents, interests, and inclinations; it is the responsibility of schools to make provision as stipulated by legislation.

Early education in Germany tends to be very similar all over the country; but with regard to secondary education, however, several German states tend toward a division into three types of schools (cf. Bals, 1999). School legislation does provide for the possibility of specially supporting the gifted. Such provision includes inner differentiation, flexible enrollment in the first grade, grade skipping, the use inclination courses, electives and free-choice requirement courses, as they are included in the curriculum. In the 'new' federal states there is also school legislation taken over from the former German Democratic Republic (GDR), which largely still follows the previous system of support for talented individuals. This legislative legacy allows for some schools to support the particularly gifted by following a special curriculum as well as offering a diverse array of extra-curricular activities (Sprengel, 1999a). There are currently 26 special schools in the new federal states of Eastern Germany promoting gifted children, all of which are part of the GDR legacy.

Following the German Unification in 1990, however, many of these schools were taken over by new sponsors (other than the state). Nine of them are devoted to Mathematics and the Natural Sciences, eleven specialize in the Arts and in Music, and six focus on Modern Languages. In addition, three schools

support and specially promote intellectually gifted students, namely the Landesschule Pforta, The Free School at Rostock, and Torgelow—which is a private secondary school (a so-called 'gymnasium'). However, there are also special classes: one at the Jugenddorf-Christophorus school in Braunschweig and one at the Christophorus school in Rostock, that cater to talented children from the 9th grade. Since 1985, in the state of Baden-Württemberg state-wide enrichment courses at secondary school level were established (Hany & Heller, 1988) and in a large-scale investigation evaluated (Hany & Heller, 1992; Heller & Hany, 1993). Furthermore, statewide acceleration programs for highly gifted students from the German Gymnasium have been implemented in Baden-Württemberg (Heller, Neber & Wystrychowski, 1993; Heller, Osterrieder & Wystrychowski, 1995; Heller & Reimann, 1999) and in Rhineland-Palatinate (Kaiser, 1997). For an overview of the concerned program evaluation studies see Heller (1995b). In the state of Bavaria, the Ministry of Culture is planning to launch three special support classes for students commencing school during the 1999/2000 school year in Munich, Nürnberg, and Regensburg (Sprengel, 1999b). Two years ago, a combined acceleration-enrichment program was established at the Maria Theresia Gymnasium in Munich. In addition, there are special classes, particularly for Music and Sports, at a number of German gymnasia. Considering former GDR's considerable prowess in Sports, it is not surprising that, as part of the East German legacy, 20 gymnasia devoted to Sports still remain; this should be compared to only nine similar gymnasia in the rest of Germany ('Kleine Sportasse', 1998).

One particularly significant German initiative in Gifted Education was taken by 'Jugenddorf Hannover' in 1995 to make provision for highly able children already in kindergarten and in primary schools. When leaving kindergarten, children enter a primary school, which has developed a program much along the lines of the proceeding kindergarten. In this environment children learn in mixed-ability groups, but the special needs of the gifted children are taken into account and are carefully monitored and supported (Hartmann, 1998). The Jugenddorf Hannover also offers advisory services for parents and highly talented children regarding identifying giftedness and discovering means of support. Such advisory channels are also provided by the Jugenddorf-Christophorus schools at Braunschweig and Rostock. More counseling and advice are available through the institutes of psychology at the universities of Hamburg, Munich, and Tübingen. The first German Counseling Center for the Gifted was founded in Hamburg in 1984/85 (Feger & Prado, 1986), another one in Munich 1987 (Heller & Geisler, 1989; Heller, 1992a, b, 1993). The main emphasis is on individual counseling for parents, teachers, and gifted pupils as well as in giving advice to schools on how to

recognize and further giftedness; meanwhile, further counseling centers were established, e.g. with the support of the municipal government in Hamburg (Quittmann & Manke, 1998).

Extracurricular support in Germany is apparent in regional and state contests, conducting work groups, correspondence networks, and specialist camps or art studios, along with summer schools and camps, which are offered through the 'Deutsche SchülerAkademie' (Pupils Academy) and others. There are competitions for talented and motivated pupils, such as 'Jugend forscht/Schüler experimentieren' (Young people's research/Students experiment), which is a Natural Sciences contest. There are also selection rounds for the International School Olympiads in Mathematics, Physics, Chemistry (see Engel, Gronau, Langmann & Sewerin, 1999; Heller & Lengfelder, 1999, 2000), Biology, and more uniquely: to a federal German environmental competition too. Able students may also show their prowess in different Language competitions, Political Education, German and Contemporary History contests, as well as in the Pan-European contest 'Europe in School'. In the domains of Music and Culture there are further competitions in Rhetoric, Creative Writing, Singing, Drama, Film and Video-making, and in musical composition: Young People Making Music, which is a federal contest (Bildung und Begabung e. V., 1997).

The 'Deutsche SchülerAkademie' was started as a special form of supporting talented and interested young individuals in out-of-school fields of pursuit. It was initiated by 'Bildung und Begabung e.V.' at Bonn in conjunction with the Federal Ministry of Education and the Sciences, and evaluated by Neber and Heller (1997). Since 1988 it has provided holiday programs for able students. In 1993, however, the German Parliament—and in 1994 by a unanimous vote at the Ministry for Culture's Conference—a permanent federal budget was set to form a starting point for supporting gifted and talented individuals. Since 1988 over 3000 highly able students have participated in the holiday courses offered (Bildung und Begabung e. V., 1998). For greater detail see Peters, et al. in this handbook.

In higher education, a dozen (and more) gifted supporting programs exist in Germany. Ten of these were evaluated in recent years (Heller et al., 1997; Heller & Viek, 2000).

Some teacher training in Gifted Education is on offer in Germany, and specific programs have been developed (Heller, 1992a, b, 1995a, b, 1996, 1997a; Neber, 1995; Heller & Ziegler, 1996; Ziegler & Heller, 1998, 2000). The international MA study program 'Psychology Excellence' at the University of Munich is one pioneering initiative in gifted education and research. This pilot program conveys, to educators and psychologists, the issues relating to recognizing and supporting giftedness. It runs as a four-semester continuing

education program (cf. <http://www.paed.uni-muenchen.de/excellence/>).

Germany also hosts a number of organizations and associations with a wide range of activities pertaining to talent and giftedness. There is the 'Hochbegabtenförderung e. V.', established by parents. It offers a total of 63 courses for 470 children in 13 German cities. The organization also offers individual assessment and counseling to gifted children and their parents. Furthermore, the 'Deutsche Gesellschaft für das hochbegabte Kind e.V.'—founded in 1978—has 3000 members in 15 regional groups and also organizes advanced courses for children, as well as arranging special days of study at the universities. It provides advice to parents, does a wide range of publicity work, and arranges activities for entire families with gifted children. 'Müsteraner Zentrum für Begabtenförderung' is yet another German association focusing on giftedness and contributing to special provision. In addition, 'Bildung und Begabung e.V.' organizes competitions, the courses of the 'Deutsche SchülerAkademie', and is of particular interest to the European perspective, since the organization has strong links with the 'European Council for High Ability (ECHA)'. Furthermore, 'Arbeitskreis Begabungsforschung und Begabungsförderung e.V. (ABB)' in Rostock, is an association of researchers, educational policy-makers, and teachers, supporting giftedness research, and aims at integrating research findings into actual teaching (cf. Urban & Joswig, 1998).

Not all of the numerous German initiatives started over the past few years can be presented in detail here for lack of space. Yet the initiatives mentioned do signify that a considerable effort is being made to bring gifted education more into the foreground of education as well as providing a solid base for it (Heller, 1995c, 1997a, 1999; Heller & Hany, 1996).

### Italy

Supporting the highly gifted is not a recognized issue in the educational policies in Italy. Although an interest in higher ability and talent is clearly emerging in Italian society as a whole, the notion of suspected elitism, the fear that non-liberal and undemocratic education could be rekindled and, because of this, that efforts towards gifted education therefore could be misunderstood, present a problem in the current Italian debate. As a result suggestions of establishing, for example, special schools or specially designed curricula, are indeed met with interest but are not put into action. The Italian experience regarding educational strategies for highly able children is therefore, by and large, limited.

However, private pre-schools for gifted, and generally for upper class children, have been organized, but these have so far had only limited success. There are also a few private schools, usually supported by the Roman Catholic Church, as well as a few universities, which previously selected students on the basis of

financial as well as intellectual ability, thereby potentially creating a mainly social elite. These schools are akin to the place and status of the famous boarding schools in the English educational tradition. However, Italian authorities now prohibit this type of selection for education, and as a result educational initiatives and research lean toward the general rather than toward the particular. Authorities seek to support ability, avoid any obstacle for development, and to seek out and promote possibilities for developing excellence. Research programs at the Universities of Genoa, Pavia, and Rome, for example, are currently studying the development of social and moral learning and motivation, the way gifted individuals live and behave, and identification by means of adequate testing—without the need of a separate educational environment for the gifted student. Research results have been presented at international conferences, and one workshop on creative potential has been held at Pavia in 1994 in cooperation with the ECHA.

In Italy, as well as in many other European countries, there are competitions; however, these tend to be staged by private sponsors, who arrange competitions in Mathematics and in the Sciences as well as in the Arts (Painting, Writing, and Film Making) (cf. Pagnin, 1994).

#### Portugal

Educational provision for high ability in Portugal is not handled in a manner similar to traditional special education; that is, to regard special education as mainly including a variety of learning difficulties, physical disabilities and social-emotional disorders. There is in Portugal a concern for educational differentiation, which took legal form during the 1990s in ratifying and publishing the General Law for the New Reform, in which the rights of students' 'different learning rhythms' are made a specific issue. This legislation, indirectly, also paves the way for accepting the special needs of gifted children. For example, the Portuguese Department for Basic Education (DEB) published and distributed a brochure to all primary schools entitled *Gifted Students*, and by legislation the Department made possible for gifted students to begin their compulsory education at age five instead of at the mainstream age of six. In 1996 DEB launched and implemented a project to specifically support intellectual precocity: 'Projecto de Apoio ao Desenvolvimento Precoce (PADP)'. It provided extracurricular enrichment for students in primary and intermediate level schools.

There are also special courses for teachers available in Portugal, and conferences are held aiming at informing and promoting creativity in schools, as well as making teachers sensitive to the special needs of the highly able. In 1997 two such conferences were held in Lisbon and in Palmela (Martins, 1997).

Special endeavors to promote giftedness consist of available summer programs. For example, the Portuguese Center for Creativity, Innovation and Leadership (CPCIL) has provided summer programs for talented students since 1989. The Center cooperates with DEB and summer program participants are invited to take part also in the PADP. These programs are aimed at general enrichment, such as divergent thinking, communication, and leadership skills. In July of 1998 the DEB organized a similar summer program for 150 participants to which highly able students from grades 3 to 9 were invited. This particular event should be considered the first *official* summer program for highly able students ever staged in Portugal.

There are three private non-profit associations in Portugal devoted in various ways to giftedness; in 1986 the Association in Portugal for Gifted Children (APGC) was created; it organizes conferences and has also made available relevant publications. In 1989 the Portuguese Center for Creativity, Innovation and Leadership (CPCIL) was founded by parents and teachers in order to disseminate knowledge of identification and provide counseling, enrichment sessions, teacher training, conferences and summer programs for Portuguese and foreign students, making interchange and partnership with other similar associations abroad possible. Furthermore, in 1995 The Portuguese Association for the Study of the Problems of Intelligence, Creativity, and Talent (APEPICTA) was launched and staged a conference (cf. Martins, 1997). All three associations have been instrumental in changing how giftedness is perceived in Portugal and have been of considerable value in providing significant assistance in a large number of cases, where children have been identified as gifted.

#### Spain

There has been a growing awareness in Spain, since the 1970s, that there exists a need to cater to diversity in education and to provide personal attention to students. However, not until important changes were made in the educational legislation (particularly the 'Ley de Ordenación General del Sistema Educativo—LOGSE, 1/1990, 3 October'), did a more systematic development towards gifted education become possible. The new legislation has many implications for the education of gifted children. High intellectual ability is indeed represented in the legislation as a bona fide category of special educational needs. As a result, the Ministry of Education has issued various legal measures to cater to diversity. The 'Real Decreto 696/1995', Article 3.2, however, stipulates that gifted students must be educated in regular teaching and programs but that there is also a possibility for such students to attend specialized centers of education. Furthermore, other legal stipulations (e.g. The Order of 24 April 1996) state that compulsory schooling should be made more flexible for students who are academically gifted;

and the most recent legal development (The Resolution of 29 April 1996) actually outlines procedures to be followed to help educators and schools to implement the educational needs associated with high ability. This Resolution establishes the following available provision: early entrance to the school system, grade skipping, an appropriate form of psychopedagogical assessment, the use of special curricular measures, and ways of guiding the highly able in accordance with their educational response.

Thus, acceleration in the form of early entrance or grade skipping is now possible. School enrollment may be reduced by two years, but this may be done at only one grade level. Enrichment in the form of special measures like grouping or restructuring schedules and locations, however, still need to be put more into practice to gain enough experience for effective procedures to be found. Researchers and teachers are increasingly becoming aware of the need to make the teaching-learning process more flexible, and to adjust teaching to the pace and needs of the individual.

Support programs have been developed, which aim at supporting gifted children individually or in groups (cf. Martin Bravo, 1997, Prieto Sánchez, 1997; Aceveda & Sastre, 1998; Touron, Iriarte, Reparaz & Peralta, 1998). In order to prompt the development of such programs into appropriate and consistent practice, teacher training programs have also been developed; such further training opportunities for teachers are to be launched at the University of Madrid. These will target two main issues, namely the development of specific diagnostics and identification instruments and the planning and development of suitable programs of action. In addition to teacher training there are also summer schools aiming at supporting the families of gifted children; international exchange programs have been developed. In 1998 university staff, teachers and researchers, with an interest in the study and promotion of high ability, established an organization: 'Sociedad Española para el Estudio de la Superdotación' (cf. <http://www.ucm.es/info/sees>), which publishes *FAISCA (Revista de Altas Capacidades)*—a national scholarly journal devoted to the study of high ability.

#### Switzerland

In Switzerland the Kantons (i.e. Switzerland's administrative regions) have authority regarding matters of education, and the need for gifted education is only slowly finding its way into the educational policy agendas of individual Kantons. At universities, for example the University of Zürich, work relevant to the highly gifted is anchored in the realm of special education. But universities do not have a direct influence on educational planning or its implementation. Since the end of the 1980s high ability has increasingly become a publicly discussed issue in the German and French speaking Kantons, but it is still largely ignored in the Italian speaking Kantons. There

has been some coverage in the national media since 1997, brought on by pressure from the press and public interest in this field. The state ministries, however, are not yet active in this area on their own accord; but first attempts at special provision for the talented and gifted can nevertheless be discerned. In Zürich there is an experimental and special school "for artistically and athletically talented young individuals." In 1998, also in Zürich, 'Talenta' opened, which is a private primary school for gifted children. Nineteen children have been selected as students so far by means of psychological tests and interviews with the children and their parents. The program for which they have been selected is a two-year experimental program. There are private schools also at Basel ('Minerva') and Solothurn, offering special training for highly able secondary pupils. Talented athletes may attend a private gymnasium at Graubünden, and young and promising Swiss scientists may participate in 'Jugend forscht' (i.e. Young people research). In addition, 'Schweizerische Studienstiftung' (a foundation) offers talented young students the chance to participate in diverse international programs thereby gaining international experience (Schweizerische Studienstiftung, 1998).

State policies, however, are aimed at keeping highly able children in the mainstream education and there are relatively few acceleration or enrichment measures offered. In the Kanton Zürich, skipping a grade as a means of providing for able children was made possible by legislation (i.e. 'Promotionsreglement'), which allows for skipping one grade at primary level. On 27 January 1998 the Local Education Authority at Kanton Zürich, however, passed a resolution, which extended the use of grade skipping. It is now possible to skip grades at all levels of school and also, under certain circumstances, to skip more than one grade (Bähr, 1998b). The Zürich LEA based this decision on specific research, pursued between 1995 to 1997, which showed that grade skipping most certainly may be seen as one of the ways in which to reduce the often insufficient demands of achievement placed upon gifted students (Bähr, 1998a).

In the city of Zürich the first ideas and funds for an enrichment teacher (a special teacher for gifted education) are available. Individualization in the classroom is recommended, and work is under way creating new teaching and support materials for teachers. One of the first nation-wide in-service teacher seminars on supporting giftedness in schools was held in 1998 at the Pestalozzianum, in Zürich; more courses concluding with appropriate certification are planned.

#### The Netherlands

High ability/giftedness is recognized by the Dutch government as an issue in primary and secondary education. The Dutch Ministry of Education stimulated and supported specific research between 1980–1987 at the University of Nijmegen, focusing on elementary

schools, and at the University of Utrecht focusing on secondary schools; and in 1988 the Center for the Study of Giftedness (CSG) was founded at the University of Nijmegen, together with a Chair given the designation "The growth and development of the gifted child." This Chair, unique in European academia, has been held by Franz J. Mönks since its inauguration in 1988. The Center has, since it was launched, been instrumental in facilitating the development of Gifted Education and the understanding for high ability in much of Europe (cf. Mönks, 1994).

From 1988 and on, more specific attention was given to the gifted students in the Netherlands. The Secretary of Parliament recognized the importance of the subject and promoted research and study. In 1993 the Platform Gifted Education was founded on request by the government, which aims at better educational provision for gifted students and to stimulate new developments benefiting them. However, during 1998 the Platform activities decreased due to lack of funding, reflecting the increasing dominance of inclusive policies. The most celebrated policy at the moment endorses the motto "Together in school again," which signals that fewer children should attend special schools, and that regular schools should rather feature increased differentiation. Gifted children are thought to benefit more from this. However, this is rather difficult to operationalize. There is also another school form in the Netherlands, in addition to the 'regular' primary schools, namely the so-called New Schools. These alternative schools (run as Jena-plan schools, or in accordance with the ideas and philosophies of Montessori or Dalton), can more easily offer special provision for gifted students, since children tend to work individually to a greater extent than in the regular schools. There are also special schools for pupils talented in music, dance, or sports, however, and children can attend these schools from about 10 years of age.

Like in most other European countries there are various competitions (or Olympics) available in the Netherlands; these are organized by the Specialists in Curriculum Development (SLO), the Ministry of Education and/or universities in fields like Mathematics, Physics, Chemistry, and Information Technology. The participating students study either at secondary schools or at university. The aim of these Olympics is simply to promote the practice of the different Sciences; winners may continue to take part in the international equivalents or obtain a prize (up to 5000 NFG).

Other Dutch activities aimed at supporting gifted individuals include summer courses for 14 to 17-year old Europeans, which have been staged at several universities (i.e. Rotterdam, Delft and Twente at Enschede) since 1996 (Pluymakers, 1997). In addition, the Talent Support Foundation organizes summer courses in Mathematics, Arts and Culture, Economy,

History, and Sports. FACTA, another foundation, similarly organizes summer courses focusing on Computer Science (for further aspects of Gifted Education in the Netherlands cf. Mönks, 1992; Mönks, van Boxtel, Roelofs & Sanders, 1996; Span, 1992; Dijk, Kok & Poorthuis, 1996; Mooij, 1996; Peters, 1998).

'Pharos' is the Dutch parent organization, founded in 1987, and like other European sister-associations, it offers provision for gifted children and hosts weekend camps (Nawroth, 1997). The goal of the Dutch Talent Support Foundation is to offer special support; furthermore, HINT, yet another organization, promotes gifted children in terms of offering information to schools and education authorities, as well as organizing lectures, courses, and activities for gifted children.

The Faculty of Social Sciences of the University of Nijmegen, in cooperation with The Center for the Study of Giftedness (CSG) and the European Council for High Ability (ECHA), uniquely offers a European Advanced Diploma in Educating the Gifted. This postgraduate course is designed to serve teachers or others involved in education wishing to specialize in Gifted Education. The certification has been available to European teachers since 1994 (Kayser, 1994). The CSG organizes workshops for primary school teachers about once a month. In addition, there are also one-day workshops offered for secondary school teachers. Teachers receive general information in these workshops about the identification of giftedness and how one can meet the special learning needs of gifted students in the classroom.

There are some teacher training colleges that specifically offer one or two modules (one module equals 40 hours of study) for primary teachers in their third or fourth year of study. For secondary teachers special training is being planned. The first specialized course, however, will be offered during 1999 by the University of Nijmegen. More generally, there are a number of School Advisory Officers in The Netherlands who offer information about gifted education to teachers.

Although high ability/giftedness is increasingly accepted as an issue needing attention, it is still common to think that high ability does not qualify as bona fide special educational need; but due to the continued dissemination of knowledge it is most probable that high ability/giftedness will become an even more significant and accepted field of special practice and knowledge. One reason for this is likely to be the increasingly more assertive stance taken by the parents of gifted children.

### **Northern Europe, The British Isles, The Baltic States, and Russia**

#### *Scandinavia*

While egalitarianism is a problem for gifted individuals in much of Europe, in spite of considerable progress in

developing policies and special provision for the highly able, Scandinavia stands out from other European nations as exceptional in this respect. No European nation, and few in a global perspective, are likely to display and enact egalitarian convictions and policies as do the Scandinavian countries of Denmark, Norway, Sweden, and also to a lesser extent, Finland. However, the notion of equality and social collectivism in Scandinavia, at all levels of society, is best understood as an inherent cultural characteristic, in which certain political ideals have merged with indigenous traditions and sentiments, which draw on historical facts and events dating from early medieval times and the Viking Era (Sawyer & Sawyer, 1993; Persson, 1998a).

In modern times, as separate nations have emerged from a culturally and often politically common ancestry, political scientists and historians tend to speak of all the Scandinavian countries as politically similar. Together they embody 'The Nordic Model' (Pettersson, 1994). The similarities between the Scandinavian countries also in terms of social dynamics were observed in Hofstede's (1982) monumental research on international differences in work-related values. Hofstede developed, for example, the Masculinity Index (MAS) by which he compared 39 different nations worldwide. High MAS indicates, for example, an independence ideal, an achievement ideal and a propensity for embracing and promoting individual excellence. Low MAS, on the other hand, much signifies the opposite: an inter-dependence ideal, a service ideal and a reluctance to reward or promote policies or actions that would cause some individuals to excel more than others. All Scandinavian countries—except Finland—are rated as low MAS: Sweden (MAS 6), Norway (MAS 10) and Denmark (MAS 22), which should be compared to, for example, Japan (MAS 87), Austria (MAS 75) and the United States (MAS 62). Finland receives a much higher rating than other Scandinavian countries (MAS 51), which has some significance in relation to Scandinavian Gifted Education and practice.

Due to the close cultural and social relationship between the Nordic nations, one should expect that attitudes toward Gifted Education, high ability and its research are more or less shared also. Particularly in Denmark, Norway and Sweden, the basic ethos by which individual excellence is commonly considered is known as 'The Law of Jante'; an expression coined by Danish novelist Aksel Sandemose in 1933. The expression signifies the impropriety of pride of self. Therefore, no-one must believe they are 'special'. A similar expression with much the same paradoxical meaning is The Tall Poppy Syndrome in Australia and New Zealand (see Mitchell, 1991; Thompson, 1994). The social reality of this often-debated issue in Scandinavia has resulted in, as Swedish journalist Göran Skytte (1997) puts it, "a begrudging and nationally endorsed attitude of envy."

### Sweden

It is somewhat paradoxical that a nation hosting the internationally acclaimed Nobel Prize Ceremony, where highly accomplished individuals from all over the world come to collect their prestigious awards in recognition of their work, does not itself recognize politically that talent is an issue deserving particular attention in its educational system. While concern for the rights and welfare of every individual student in the regular classroom has been safeguarded in every national school curriculum since 1920, special needs have only been identified in reference to children with learning disabilities or a variety of physical or psychological disorders (cf. Rosenquist & Sandling, 1995). High ability has officially never been singled out as a separate issue in education, and amongst school teachers it is occasionally even considered unethical to argue that high-achieving children are in need of special provision (Persson, 1997a).

There exist special music schools in virtually all Swedish towns and cities available to anyone interested in music from age 6 to age 18 (Kommunförbundet, 1976). In addition, there are special secondary schools devoted to a variety of Sports and Music. It is difficult, however, to regard these as an intentional strategy to nurture talent specifically. While such special training does occasionally produce very able athletes and musicians, selection is mainly based on special interest rather than on special ability, although there are formal criteria as well as proficiency examinations in order for applicants to be accepted. However, a limited number of educational experiments have recently been launched, usually at a secondary level and in Science or Mathematics, which could be regarded as more akin to traditional Gifted Education. High-achieving students have been offered the possibility of taking more advanced courses than is typically offered at their level of education. These efforts, however, are local and limited to a handful of schools. Also, a recent action taken by the Stockholm Local Education Authority involves the creation of six special classes at primary and lower secondary levels. This particular effort is made possible by the fact that local education authorities have a certain degree of autonomy obliged mainly to make possible the targets and follow the guidelines stipulated by the National Curriculum. How these targets are to be reached falls within the jurisdiction of local education authorities. The special classes in the Stockholm school system will be in operation in the fall of 1999, and are carried out, it would seem, contrary to the wishes of the Ministry of Education. It is feasible to assume that there are political motives at the heart of these experiments, rather than a sudden understanding of the special needs of gifted children. The Stockholm City Council currently has a conservative majority, and it is possibly tempting for local politicians to act out against the Social Democratic

government, rather than to consider the actual needs of gifted children in the school system. Interestingly, and somewhat alarmingly, special teacher training has not been considered, nor have strategies by which to evaluate this type of special school or program been devised (Melander, 1995; Nyman, 1998).

Swedish educational research over the years has indeed focused ability differentiation in the regular classroom (Husén, 1948; Gustafsson & Härnqvist, 1977; Dunér & Törestad, 1980), but it has been difficult to reconcile discovered variety and different levels of ability with dominating political ideals and cultural traditions forming the basis of national curricula (cf. Husén, 1979). Above all, education “plays a crucial role in supporting active citizenship and makes it possible for individuals to employ citizens’ rights and meet necessary civic obligations” (Ministry of Education and Science, 1993, p. 125).

In Sweden formal groups and organizations tend to be strong and influential in contrast with individuals, who are generally considered weak and are often ignored; a tradition much influenced by dominant political ideals. Daun (1994) argues the considerable influence of the Swedish Social Democratic party, which has been in power with few interruptions since 1932. Due to the fact that individuals are largely legitimate only if representing a group, Daun concludes, that

Swedes are ambivalent about their ‘stars’ . . . whether in sports, show business, or culture. Successes may be admired, but their exclusiveness and out-of-the-ordinary achievements often give rise to envy and therefore to malicious pleasure when the stars ‘fall’. The high value awarded to *sameness* makes all personal success problematic (p. 107).

The notion of sameness also applies to Swedish education. Edfelt (1992), for example, points out that in Sweden “it is considered undemocratic not only to be mentally gifted, but also to be gifted and demand special treatment because of this fact” (p. 47).

While high ability and individual success may not readily be acknowledged in individuals, it is certainly recognized if occurring group-wise. One curious example of this—qualifying *both* as group-orientation and elite-orientation—is the so-called ‘Gnosjö spirit’. Gnosjö is a small community in South Sweden in which entrepreneurial talent and prowess in the realm of small and medium-sized businesses is flourishing quite independently of political guidelines and policies decreed in Stockholm, making the area not only financially very affluent, but it also knows virtually no unemployment (Karlsson & Larsson, 1993; Gummeson, 1997). This phenomenon has been subject to much study and praise by politicians and researchers alike and, interestingly, more or less regardless of their political creed.

In spite of the cultural legitimacy of group-achievement and the collectivist protectionism of educational policies, however, one must juxtapose education with general professional practice encouraged in Swedish society as a whole. There exists a paradoxical discrepancy between stated and argued traditional values and politically encouraged behavior to support the market economy by professional expertise and talent. While education is ‘protected’ from what is argued to be ‘elitism’, elitism is indeed practiced, recognized and widely supported in professional life (Persson, 1997b). There is understandably, therefore, often a considerable disagreement between industry and governmental education policy (Nicolin, 1996). Conflicts between unique and very able individuals and the Swedish societal system has occasionally led to accusations of anti-intellectualism (Segerstedt, 1979), as well as to a certain ‘brain drain’, the most spectacular of which is likely to be film director Ingmar Bergman’s decision in 1976 to leave Sweden after a series of accusations of tax evasion (Bergman, 1987).

Some change is under way, however, and interestingly it originates in individual initiatives rather than in governmental policies or group-efforts. Individual teachers, who have trained abroad, bring back knowledge and practices of Gifted Education with them, and share this information with others (e.g. Wahlström, 1995). Implementation and effort, however, is always local and receives neither official recognition nor special funding. The most significant change, and with the greatest potential of affecting the compulsory school system in a direction commensurate with the recommendations of the European Council on education for the highly able (cf. Council of Europe, 1994), is an effort made by Jönköping University, in which all students in the comprehensive teacher training programs are provided with rudimentary knowledge of high ability and the special needs of the highly able. A special course is also available, but applicants are few (Persson, 1997c, 1998c), in spite of the fact that indigenous research has shown that Swedish teachers themselves recognize both the special needs of highly able children and their own lack of information on how to support them (Persson, 1997a).

#### Denmark

In Denmark too, the ideals of the collectivist Welfare State, have prevented high ability from growing into a particular focus of attention in education. Inclusion, as well individualization, are basic principles of the Danish compulsory school system, as they are also in the rest of Scandinavia. All children’s varied educational needs, according to Danish legislation, should be met by differentiation within the regular classroom (Tetler, 1995; Lau & Pagaard, 1996; Robenhagen, 1996). The Danish comprehensive school, as functioning under the latest Reform Act of 1993, shall “familiarize the pupils with Danish culture and

contribute to their understanding of other cultures and of man's interaction with nature. The school shall prepare the pupils for active participation, joint responsibility, rights and duties in a society based on freedom and democracy. The teaching of the school and its daily life must therefore build on intellectual freedom, equality and democracy" (Ministry of Education, 1996, p. 2).

While differentiation is a basic prerequisite to cater also for particularly talented pupils, however, there is still the problem of teachers' common sense understanding of high ability in the inclusive classroom. Their basis for dealing with talent in the Danish school is to count on such children as always being resilient; that is, they will somehow manage whatever the circumstance (Jansen, 1996).

While the philosophical foundations of educational systems in Denmark, Sweden, and Norway are virtually identical, the Danish Ministry of Education—unlike educational authorities in Norway and Sweden—has "shown some interest" in the work of a research team of educators and psychologists established in 1995 in the Danish National Institute for Educational Research at Copenhagen, whose objectives are to "investigate potential problems and their incidence in relation to talented children" (Rabøl-Hansen & Robenhagen, 1996, p. 5).

#### *Finland*

Finland, although endorsing 'The Nordic Model' also (Persson, 1994), differs to some extent from other Scandinavian countries in educational objectives and relationship to high ability. Note that Finland stands apart substantially from the rest of Scandinavia in terms of work-related values as estimated by Hofstede (1982).

While attitudes towards specific teaching for the highly able traditionally has been negative and rejecting, this is changing due to "increasing communication to educators and administrators of research findings, indicating the advantages of nurturing the highly able and the techniques to do this" (Ojanen & Freeman, 1994, p. 7). This development towards a greater flexibility in the Finnish understanding of equality, is largely due to a governmental decision to decentralize decision-making in the school system and, in fact, abandoning the concept of a national curriculum. Individuality and freedom of choice are emphasized more strongly in the Finnish school system than in any other Scandinavian country. As a result, schools have been encouraged to draft more individual curricula, which in turn allows flexible decisions for appropriate acceleration for the highly able (Tirri, 1997). This new trend of individual consideration and choice allows flexible decision-making. Parents may decide that their child is ready to start school at age six (earlier all children started at age seven), and there is a movement

towards allowing parents to choose which school to send their children to. In addition, students in secondary schools may have their study schedule more or less 'customized' due to the fact most upper secondary schools operate on an ungraded basis (Laukkanen, 1995). Also, opportunities for able children to attend extracurricular enrichment on a voluntary basis have arisen in recent years. Some primary schools, for example, arrange groups where students may advance those skills and interests in which they show talent. Such groups have so far focused on Thinking Skills, Mathematics, Computers, and the Arts within a project-oriented framework. Mathematically gifted secondary school students regularly meet at the University of Tampere and also take part in summer courses where they gain credits in Linear Algebra and Physics for later studies at university. This project is sponsored both by the Ministry of Education and Finnish Industry (cf. Nieminen & Piche, 1995).

A new strategic plan for the Finnish school system, ratified by Parliament in 1993, outlines the main objectives of education and science policy to maintain a high and varied level of training, to further spiritual growth, to encourage individual initiative and entrepreneurship, to improve education and research quality, to widen the basis for industry and strengthen innovation, to combine work, training and changing life situations, and develop further professional skills and facilitate employment (National Board of Education, 1997). This plan for the Finnish school system is unlike other Scandinavian strategic guidelines for schools and education, and does not only reflect recent political developments in Finland but also, at a more fundamental level, cultural differences. Note that there is also a growing base of original Finnish research with regard to high ability, competence, talent and its training (Merenheimo, 1991; Välijärvi, 1992; Tirri & Uusikylä, 1994; Uusikylä, 1994, 1996; Engeström, Engeström & Kärkkäinen, 1997; Rätty & Snellman, 1997).

#### *Norway*

In 1997 the Norwegian Ministry of Church, Education and Science implemented an educational reform resulting in a new national curriculum reinforcing the Nordic notion of communality. It states, as do similarly other Scandinavian educational policies, that "the school system is based on the principle of inclusion; on equality and the individual adaption of the teaching of a unifying curriculum in an integrated school system" (Ministry of Church, Education and Science, 1997, p. 1). While the new curriculum clearly states that the Norwegian school system is structured so as to satisfy both the individual student's needs as well as society's need for competence, there is little to suggest that high ability would be a particular concern. On the contrary, it appears that the egalitarian ethos is reinforced to an

even higher degree in the new reform, and to an even greater extent, than is the case in recent Danish and Swedish school reforms. It may well be, that in Scandinavia, the egalitarian ethos is strongest in Norway (Williams & Mitchell, 1989; Undheim & Nordvik, 1992).

While authorities expect that high ability as well as low ability should have their needs satisfied in the integrated and inclusive classroom, they also argue—somewhat contentiously in the light of Gifted Education research—that “all pupils aspire to achieve the same goals, and the demands of differentiation and individualization inside the class are a central concern of the teaching staff” (Arne Gundersen, personal communication, 29 September, 1998).

However, the Ministry of Church, Education and Science also points out that while there are no special schools available, and no summer schools are held for the special benefit of highly able children, schools may well take the initiative to invite experts in different fields to inspire not only students but also their teachers. As in most other European (and Scandinavian) nations there are competitions in Mathematics, Computing and Physics also in Norway attracting the talented.

#### THE FUTURE OF GIFTED EDUCATION IN SCANDINAVIA

It is not likely that the Scandinavian countries will conceptualize high ability in a way similar to, for example, Germany, Austria, The Netherlands, Canada or much of the United States. Nor is it likely that they will adopt current, and predominantly American, models by which to develop Gifted Education. That is not to say, however, that high ability will always remain of no or little interest, or that some precaution to secure the democratic rights of talented children to obtain training commensurate with their unique ability, will not be taken.

One interesting observation is that all the recent Scandinavian national curricula are implicitly approaching the notion of Multiple Intelligences (Gardner, 1983). In addition, MI-theory is increasingly seen by researchers as a way forward in which to cater to highly able children in the inclusive classroom also (Baltzer, 1996; Tirri, 1997; Persson, 1998), since—in a sense—a classroom based on the notion of multifaceted competences much bypasses the egalitarian dilemma. The social and ideological sensitivity to whether an individual is of high or low ability would become lessened by a focus on competence differentiation rather than on achievement level differentiation in a few IQ-related skills. It is likely that with indigenous values and tradition as a basis, the Scandinavian countries may well develop their own culture-specific approach to provide also for the gifted and the talented.

#### Russia and the Baltic States

##### *Russia*

One easily associates contemporary Russia, as well as the former Soviet Union, with a passion for talent and a national pride for its high-achievers, considering the number of internationally known and prominent Russian artists, athletes, and scientists. Indeed, in fields such as Painting, Ballet and Music talented children from all over Russia have been sent to Moscow and Saint Petersburg to schools, rich in tradition, for training since before the Russian Revolution in 1917. Composer Peter Ilyich Tchaikovsky, for example, argued in his time, with reference to training in music, that “schools must be started in our capital cities, and also in our regional centers and towns . . . The purpose of these schools would be to train young people for the conservatoire” (Kabalevsky, 1988, p. 139). However, the assumption that Russia also has a long-standing tradition of Gifted Education in, for example, the Sciences and in Mathematics is false. Firsov (1993) declares the early development of special educational networks to further gifted mathematicians and scientists to be a myth; and as such a Western product of the now defunct Cold War. The first special school on a secondary level, with a special focus on advanced mathematical education, was created by Semyon Schwarzburd: a Mathematics teacher in Moscow School No. 444 in 1959.

High ability is recognized politically by the Russian Government, but there are no stated priorities regarding which subjects or fields of pursuit in which particular provision should be developed. Note that in providing training for gifted and talented individuals in Russia, the term ‘gifted’ is usually avoided. For example, in Moscow, where there are approximately 1250 federal and about 250 private schools, half of these host enrichment programs (or in Russian terms ‘deepened programs’) rather than ‘programs for the gifted’.

There are both special schools and special classes available ranging in focus from Mathematics, Natural Science and Technology (cf. chapter 6, part V, in this Handbook) to Verbal Skills (including Foreign Languages), Music, the Arts, Sports as well as vocational and practical skills. A special program for Leadership was launched in 1991 and programs in Business and Management are currently under development. There are special boarding schools for mathematically gifted children from the remote and rural areas of Russia. In addition, such children may also participate in a special correspondence course hosted by Moscow State University. Interestingly, mentorship programs exist, but they have not been planned in order to reinforce educational provision; they have emerged spontaneously. Some schools use tutoring in which an expert works with a small group of students for a number of years; these experts, as a rule, are always former students of that particular school. The intention is to

transfer the best of intellectual and cultural traditions of that school to the next generation of gifted individuals, challenge them in a particular subject, and facilitate their transition from school and to university.

An extensive network of extracurricular activities—often in cooperation with universities—where highly able children may find additional stimulation for their particular interests also exists. These involve lectures, workshops, projects, fieldwork, and cooperative learning endeavors in traditional school subjects and in other more specialized subjects such as the study of Animal Behavior, Astronomy, Archeology, Cosmology, Paleontology, Folklore, Ikebana (i.e. Japanese flower arrangement), Esoterics, and so on. Special summer schools and programs are numerous. Perhaps the most spectacular example of such provision is the Summer School of Cosmonautics in the Siberian city of Krasnoyarsk.

Special schools, which are relatively few, are generally intended for the exceptionally gifted children. Training entails radical acceleration, individually tailored instruction, psychological support, creativity training and communication training (Babaeva, 1999).

General guidelines for the Russian school system do not focus talent in a mixed-ability setting. They rather emphasize the necessity for differentiation and individualization of instruction. Whether or not these guidelines are adhered to, however, is dependent on the individual schoolteachers; number of students in the classroom, teachers' workload, individual interest and enthusiasm. There is a tendency amongst schoolteachers to devote more time to children with learning disabilities. Special training for teachers regarding the nature and special needs of highly able children does exist but takes place irregularly and usually as in-service training on the initiative of the Local Education Authorities. Such training typically includes the psychology of high ability, identification, strategies and models of Gifted Education, curriculum development, and the principles of creativity training.

Gifted Education in Russia, although already extensive more or less by tradition, has to some extent lacked specific and centralized guidelines. This is changing, however, indigenous research in the field is growing stronger (cf. Leites, 1996), and a group of specialists have been working on such guidelines for some time. There is currently in press an official document that includes a general conceptualization of the giftedness construct, its assessment, types of giftedness, and what manner of provision is suitable and recommended for the stated types of giftedness. The document has recently been approved by the Ministry of General and Professional Education of the Russian Federation. This further development is linked to the current Post-Communist turmoil, in which far-reaching reforms are creating transitional difficulties. During this transition, however, a particular concern has been expressed that gifted individuals must not be

wasted or overlooked in the course of societal change. Rather, they represent a necessary national investment, which eventually may help to solve the crisis. One example of this concern is the latest federal program Gifted Children, launched in 1996 and constituting an important part of the Presidential program Children of Russia.

### *Latvia*

To nurture talent is essential also to the Republic of Latvia; one of the Baltic nations, and largely for the same reasons high ability is becoming increasingly important for Russia and in the rest of former Communist Europe. Inara Akmene (1994), of the Latvian Ministry of Education and Science, declares that "the education of highly able school children is essential to Latvia. We work together with universities and public organizations to bring up a generation of talented young people, who in due time may constitute the intellectual basis of this nation" (p. 8).

High ability is thus endorsed politically in Latvia, and has been the focus of particular interest for many years. The Ministry of Education and Science at Riga, for example, hosts the Educational Advancement Institute; a body specifically assigned to promote competitions (usually termed Olympics), programs and activities for gifted and talented children and adolescents. Such provision rests mainly on all-year mentorships, seasonal enrichment programs (such as summer camps), and an abundance of competitive opportunities in several fields and disciplines. Highly able children are likely to be assigned to expertise from the universities; be it either in Mathematics, Physics, Chemistry, Biology, The Visual Arts, or in Modern Languages. There are incentives for university staff to participate in these schemes. A particularly successful mentor, in recognition of his or her success, may be eligible for the Atis Kronvald's Prize. No specialized training is provided to prepare these mentors for their role nor is such training available for school teachers.

The success of programs, courses, and studies, is always tried in a variety of Olympics on different levels, from subject competitions in single school units to nationwide and international competition, where number and type of prizes are important to local as well as national self-esteem. As in Russia, competitions and provision for mathematically prodigious children appear to be regarded as particularly important, as well as particularly prestigious (cf. Andzans, undated).

### **The British Isles**

#### *England and Wales*

The status of Gifted Education in England and Wales is somewhat paradoxical; the issue exists as such in education. It is frequently the focus of debate in a complex social setting, where stratification is relatively distinct (cf. Giddens, 1989). Class consciousness exists

alongside a tradition of very prestigious schools for the social elite, the political and egalitarian ideals of the working class, influential charities, and parent organizations of the middle class. In addition, there is a strong academic tradition of research on the various aspects of ability. The current international knowledge base of high ability owes a great deal to well known scholars such as Sir Francis Galton, Charles Spearman, Philip E. Vernon and more recently Hans-Jürgen Eysenck, Richard Dawkins, John Sloboda, John Radford, Alan Baddeley, and many more. Indigenous research specifically focusing on Gifted Education, however, is still scarce (Freeman, 1998), whereas specific literature for parents of highly able children, and for teachers interested in Gifted Education, is readily available (Denton & Postlewaithe, 1985; Leyden, 1985; Freeman, 1991; George, 1992; Young & Tyre, 1992; Faludi & Faludi, 1996; Montgomery, 1996; Eyre, 1997).

Recognizing and nurturing high ability has, in a sense, been an integral part of English society for a long time. Interest in high ability, however, has been largely class-bound, and has become a part of the sometimes conflicting interests of the higher and lower strata of English society. This conflict has occasionally also been voiced in research. Howe (1990), for example, argues in over-viewing the traditional nature/nurture problem, that

it may be comforting for recipients of a privileged upbringing to have chosen to believe that Nature has ordained some people to be born quick-witted and others dull, some to lead and the remainder to follow. But the findings of empirical research contradict this conclusion (p. 57).

It needs to be pointed out, therefore, that while elite training in English boarding schools has a long-standing tradition—often hailed and commended for its excellence—it has, in fact, little to do with the growing recognition of the need to establish Gifted Education as based in the national school system. The famed tradition of English boarding schools is above all a matter of *social* positioning in society, where high ability certainly is an expressed target, but where tradition and a certain social fostering are likely to constitute a more powerful *raison d'être* than is differentiation and concern for ability profiles of individual students. Such schools may, contrary to belief, not necessarily facilitate the development of high ability. It is known by research that this type of institution may well have a long-term negative impact on the emotional lives of their pupils. They tend to foster in some children a particular style of coping whereby distress is actively suppressed from consciousness rather than confided in someone willing to listen (Boyd, 1985; Fisher, Frazer & Murray, 1987; Harris, 1989).

Due to the dominance of politically egalitarian convictions, as in the Scandinavian countries and in former Communist Europe, resistance to focus Gifted Education as a separate issue in the English school system—irrespective of the existence of traditional elite schools—has been formidable (cf. Young & Tyre, 1992). The process of recognizing the notion of special needs in education as inclusive of provision for the highly able also, has been a long one and, interestingly, largely separate from government decisions and legislation. High ability is not recognized, for example, under the Special Needs Legislation of 1981 and 1993, which also conveys the principle of inclusion: special needs should be provided for in the regular school (O'Hanlon, 1995). The provision for gifted and talented children in schools has nevertheless been the specific focus of officially commissioned reports (DES, 1977; HMI, 1992; Eyre, 1995; Freeman, 1998), or mentioned by these as an issue in need of serious consideration (DES, 1979; Askew & Wiliam, 1995).

As early as 1973—preceding the Warnock Committee Report on Special Education (DES, 1978), which to some extent accelerated the interest in providing for highly able children too—The Department of Education and Science in London offered a first course for teachers on the special education of gifted children. In-service training of teachers has continued, and some research on how best to implement such training is being pursued (Clark, 1996, 1997; Montgomery, 1997).

Note that teachers and parents organizations have been of paramount importance in prompting a development towards special provision for gifted and talented children in England and Wales (cf. Freeman, 1995). The National Association for Gifted Children (NAGC) was founded in 1966 by parents to promote knowledge of high ability, and in 1982 the National Association for Curriculum Enrichment and Extension (NACE) was founded by, and for, teachers to support teachers nationally in matters pertaining to the education of gifted and talented children. More recently NACE has also established a research center at Westminster College, Oxford: The Centre for Able Pupils.

Implementation of Gifted Education, always subject to egalitarian legislation—and influenced by parents and teachers organizations—has been mainly the concern of Local Education Authorities (LEAs). For example, in 1992 about 35 LEAs (out of a total of 108) were employing at least one individual with official responsibility for the gifted (Freeman, 1992), and five LEAs had one person employed with highly able children as their *sole* responsibility (Raffan & Short, 1992). Development towards national guidelines for Gifted Education, however, is slow (DES, 1989), and Freeman (1998) expresses some doubts as to a central and immediate political solution to the problem. The 1995 revision of the new National Curriculum has to some extent opened up to high ability provision

through the so-called Access Statement, which declares that “for the small number of pupils who may need provision, material may be selected from earlier or later key stages where this is necessary to enable individual pupils to progress and demonstrate achievement” (cf. Freeman, 1998, p. 53). The level description for each Attainment Target in the National Curriculum also addresses ‘exceptional performance’ and does mention ‘very able pupils’. However, it would appear that, at least for the time being, the further development and advancement of Gifted Education in England and Wales, rests mainly with individual schools and the local policy adopted on how to make provision for the highly able child (Eyre, 1997; Freeman, 1997, 1998). The number of schools expressing an interest in such policies is steadily on the increase. For example, there are presently ten experimental classes set up all over England geared towards special provision. In addition, a group of advisors has been set up to guide the British Government in the further development of Gifted Education, and a group of Members of Parliament has very recently launched a special investigation into the education of the most able (Joan Freeman, personal communication, 5 January, 1999). Freeman (1998) points out that this “accelerating development is likely to be the result of some government guidance, official and government-supported conferences and free publications focusing high ability, school standards in education inspections, parents and teachers organizations, as well as due to the recent large-scale NACE/DFE-project entitled Supporting the Education of Able Pupils in Maintained Schools” (cf. Eyre, 1995), which involved some 20,000 teachers in 37 LEAs.

### Is There a Specific European Approach to Gifted Education?

Europe is a continent with a great deal of cultural, ideological, and economical variety. This is clearly reflected in the way Gifted Education is approached and valued. European ideals may be *ideologically* and *culturally* divided between policies striving for differentiation and policies promoting similarity, which largely divide the Continent in two halves: one Northern part and one Southern/Eastern/Middle/Western part. While special provision for the highly able is an expressed education-political agenda, albeit not always uncontroversial and legislated, in Southern, Eastern, Middle and Western Europe, Northern Europe (i.e. Scandinavia) largely resists any attempt to single out any individual in educational contexts for any reason, since generally the group is the culturally decided unit rather than the individual. It is often more important to be similar rather than different.

In spite of the demise of the ‘Iron Curtain’ between Communist and Non-Communist Europe, however, the continent is also divided in an Eastern and a Western part depending largely on current differences in

national economies. This divide creates an interesting discrepancy between East and West as far as Gifted Education is concerned.

On the assumption that high ability is essential in promoting the development of a nation’s Industry, Science, and Economy, all of former Communist Europe has embraced Gifted Education with some fervor and ingenuity; which in part is reviving a rich cultural tradition, that was largely dormant and suppressed during the time of Soviet influence. This part of Europe, however, currently lacks the financial means, and in some cases also efficient administration and organization, to implement their intentions, and bring to life again their interest in providing for talents. There is also little controversy in the East parts of Europe regarding Gifted Education.

In Western parts of Europe (including Scandinavia), however, national economies are relatively strong; there is generally no lack of funding for national education; but while high ability is recognized as instrumental in professional life and in competing with other world economies—professionally, developmentally and scientifically, Gifted Education is paradoxically a controversial issue, although more so in some countries than in others. This resistance tends to be ideological in nature, and is perhaps based on the fear that promoting an elite, which potentially could supersede democratic principles, could also proceed from being an intellectual/professional elite to becoming a social and exclusively privileged and potentially secluded elite. However, such fear is largely unwarranted. Most sociologists agree that no democracy can, in fact, exist without the support of an elite (Giddens, 1989).

The sensitivity of the issue in most of Western Europe has prompted national school systems to opt for Inclusive Education as recommended by the so-called Salamanca Statement, on the assumption that all children’s educational needs can be satisfied, more or less, within the regular classroom in a mixed-ability setting.

The nations of the Western part of Europe, therefore—to the extent that national education authorities recognize the need of special provision for highly able children—enact Gifted Education mainly in an inclusive setting (see Table 1). For such endeavors to be successful, specific teacher training, means of instruction, research, and school system flexibility, are of the utmost importance. Significant to this development is the fact that the European Council—a body for inter-governmental cooperation between 25 European states—issued a recommendation for all of its member states in 1994 regarding, specifically, the education of gifted children (Council of Europe, 1994). This document recommends all member states

- to legislate for the special educational needs of gifted children to be recognized;

- to promote research on identification, the nature of success, and reasons for school failure;
- to provide information on gifted children and in-service training for all teachers;
- to make special provision for gifted children *within* the ordinary school system (i. e. Inclusive education);
- to take measures to avoid the negative consequences of labeling someone as gifted and talented;
- and to promote debate and research amongst psychologist, sociologists, and educators, on the
- vague and relatively undefined giftedness construct.

This document carefully addresses the sensitivity of the issue by emphasizing, that “special educational provision should . . . in no way privilege one group of children to the detriment of the others” (p. 1).

Is there then a typical European approach to Gifted Education? Clearly, the conditions for developing provision for the highly able are unique in the sense that the complexity of the issue demands European-based research to find ways of implementation, and to develop strategies commensurate with the psychological nature of highly able individuals, compatible with the cultural legacies of Europe, and agreeable to current political ideologies. The variety of problems encountered in developing Gifted Education, however, is not unique to Europe. Suspicion towards high-achievers, irrespective of their field of pursuit, is a problem in Scandinavia (Daun, 1994) as well as in Australia and New Zealand (Mitchell, 1991; Thompson, 1994), and to some extent also in the so-called Third World (Raina, 1996); and allegations of school systems nurturing anti-intellectualism have been made

Table 1. An Overview of Different Aspects of European Provision for the Gifted and Talented.

**Legend:** Note that legislation refers to legislation specific to making provision for the highly able. Similarly, schools and classes refer to specially designated learning environments (also specially designated higher education)—private and/or state-controlled. Extracurricular pertains to all manner of provision or specially designated activities, which are not part of a school system. By training is meant all types of teacher training, either by in-service training, specially offered courses, or unique teacher training programs. Other includes means of provision typical of inclusive strategies such as grade skipping, within-class provision and/or a variety of enrichment strategies.

<sup>a</sup>There is legislation in a few federal states, especially in the ‘new states’ of former GDR.

<sup>b</sup>Note that these are six experimental classes, launched in 1999 in Stockholm by initiative of the Stockholm LEA.

<sup>c</sup>Note that these are experimental classes.

in the United States (Howley, Howley & Pendarvis, 1995) as well as in Sweden (Segerstedt, 1979).

To be different than most others has probably always been a dilemma in any culture and in any historical era; and being exceptionally able is only one possible way in which an individual may be different from others (Persson, 1999). Berenson's (1959) definition of 'genius' in the world of Visual Arts as "the capacity for productive reaction against one's training" (p. 201), for example, speaks of the potential and social impact of creating something new. Hence, by implication, to be 'deviant' from what is considered the general norm, is also to be made suspicious by peers and contemporaries holding on to that norm. There is safety in recognition and in that, which is generally accepted. Common to all nations, presumably, are abilities, which deviate from accepted norms by level or nature. Many of the problems encountered by implementing Gifted Education worldwide are likely to be the same rather than unique, or at least related, on social-psychological grounds.

It is likely, however, that in time Gifted Education will be established in a way unique to Europe, the reason being that such provision will need to follow not only psychological characteristics, and specifically European needs, but also the culture of which the gifted psyche is an inevitable part.

### Acknowledgements

The authors would like to extend their gratitude to the multitude of staff at European Embassies and Ministries of Education and Science, who have willingly and expertly assisted us in providing current information relevant to high ability and Gifted Education. We are also particularly indebted to the following individuals, who graciously and exhaustively contributed their considerable professional experience in their respective countries as well as material and relevant information, which was not readily available by any other means than by colleague-to-colleague contact: Inara Akmene, Juan A. Alonso, Lidija Arambasic, Konstatin Bähr, Kirsten Baltzer, Dominique Barthélémy, Edward Chitham, Carmen Cretu, Carl D'hondt, Vladimir Dockal, Ivan Ferbezer, Joan Freeman, Margarida Goveia Fernandes, Arne Gundersen, Jarkko Hautamäki, Annette Heinbokel, Kurt A. Heller, Liane Hoogeeven, Thomas Köhler, Ole Kyed, Wiesława Limont, Theo Mardulier, Sylviane Monnier, Franz J. Mönks, Tetyana B. Partyko, Willy A. M. Peters, Ludmila Popova, Vagn Rabøl-Hansen, Katya Stoycheva, Kirsi Tirri, Javier Tournon, Kari Uusikylä, Vlasta Vizek-Vidovic, Vesna Vlahovic-Stetic, and Levcho Zdravchev.

# Russian Gifted Education in Technical Disciplines: Tradition and Transformation

Elena L. Grigorenko<sup>1</sup>

## Introduction

Russia's program of education for the gifted in maths and science has undergone tremendous change since the late 1980s. Once a centralized program that carefully selected, trained, and harnessed young talent, it can now best be described as a mosaic of traditional and innovative forms—an uneasy combination embedded in a context of pedagogical, financial, social, and political challenges.

All Russian children are familiar with a specific type of mathematical problem, in which Train 1 leaves Station A bound for Station B, while Train 2 departs from Station B and travels toward Station A. Although there are parallel tracks for two-way traffic, both trains must, at a certain point, pass through the same switch in railway track. If the trains arrive at the switch in track simultaneously, they will collide. The problem specifies the distance between Stations A and B, the distance from both stations to the switching point, and the time constraints of the train schedules. The students' task is to calculate the speed at which each train must travel to avoid a collision.

Metaphorically, this simple maths problem evokes the present dilemma confronting the Russian system of gifted education. Train 1 represents the inertia of the traditional centralized and controlled educational system, while Train 2 symbolizes the momentum established by recent developments beginning in the late 1980s. The trains departed from different places, but at some point they must pass through the same switch. The choices are that they can collide, pass each other without rendering an explosion, or, unlike it goes in the maths problem, get assembled in a single train. Somehow, Russia must find a way to integrate these two systems.

Unfortunately, the task before Russia is more complicated than the schoolchildren's train problem. We are not certain how far apart—how truly distinct—

the two educational strands are, and we cannot be sure when each much be reconciled with the other. Nevertheless, the 'trains' have left their respective stations, and decisions about the future of gifted education must be made. We need to understand, first, the defining features of Train 1 (the 'old' way) and Train 2 (the 'new' way); and, most importantly, we must determine how these different ways of schooling can be brought into productive harmony within the Russian educational system. How, in other words, can we avoid an educational 'train wreck'?

## Train 1: Hallmarks of the Old Way

In Russia's traditional regular classes, all students received virtually identical training; they used the same textbooks and took the same exams. The Ministry of Education and local educational authorities established the programs to be carried out in regular classrooms. No schools could do less; but they could do more.

In general, the old system of gifted instruction pursued the following goals, in descending order of importance: (1) education for the good of the whole society, (2) education to promote progress, and (3) education for the personal growth of the individual. Society's needs came first, and technological and societal progress took second priority; personal development for the sake of the individual was the least important of the three major goals.

The system of education for the gifted was designed accordingly. To capitalize on the nation's intellectual resources and further the reputation of Soviet society, the designers of the system established a network of competitions. These contests identified gifted students, whose talents were then developed through extra-curricular support and specialized schooling. The Russian system of intellectual competition has been evolving for over 50 years and includes competitions of multiple types and levels (school, district, town, region, and so on). Particular emphasis has been placed on the preparation and support of students engaged in international competitions. The most widespread types of intellectual competitions are olympiads,

<sup>1</sup> Department of Psychology, Yale University, New Haven, Connecticut, USA. E-mail: elena.grigorenko@yale.edu

tournaments, long-term extramural courses/competitions by correspondence, and pupils' conferences. These competitions present competitors with different sorts of tasks and feature a variety of structures and time constraints. Their major function, however, has been consistent: to identify talent (so that it could be developed to society's advantage) and to demonstrate Soviet/Russian achievement.

The second traditional goal of gifted education—assuring 'progress'—was accomplished by engaging talented youth in solving 'real problems'. Competitions and fairs exposed gifted children to the most advanced ideas. The problems and topics addressed at these events were those of concern to professionals working at the cutting-edge of their fields. In addition, most leading specialized schools for the gifted were run by Soviet academics. For example, Math-Physics school #18 was founded as an offshoot of Moscow State University's Department of Math and Mechanics by the famous Russian mathematician Alexei Kolmogorov. The majority of the teachers in this school were university professors, and many of the students conducted scientific research in the professors' labs. The gifted were channeled through a system—consisting of identification, different levels of education, and then work in appropriate jobs—carefully designed to develop and then harness their talents for 'progress'.

The achievement of the third goal—the optimal development of the individual person—was the least crucial in the old system. In fact, little organized support existed to further this aim. For one thing, specialized education emphasized learning in certain domains of giftedness (e.g. maths and science) and paid little attention to other subject areas (such as the humanities and the arts). (In fact, this was characteristic of Soviet education in general. In regular schools great attention was paid to the teaching of maths, physics, and other general sciences. However, instruction in the humanities was shaped, to a large degree, by ideology, and schools largely ignored the arts.) Second, students received little social and emotional support; up until very recently, no gifted programs utilized professional psychologists or social workers. Third, gifted education programs minimized the role of parents, who were rarely consulted. Moreover, only a few cities had day schools for the gifted, so in many cases gifted adolescents were placed in boarding schools far away from home.

Nevertheless, gifted education rewarded individuals for natural gifts. Compared with their less-talented counterparts, gifted children attended better schools (and, in the case of boarding schools, the government paid for tuition, room, and board), had better teachers (often teachers working with gifted children also taught at universities), gained access to more esteemed universities (participation in intellectual competitions and diplomas from certain schools were 'tickets' to the best universities), and received more desirable jobs

(special governmental committees assigned jobs such that higher-achieving students had better choices than their less-accomplished peers).

Traditionally, gifted education focused on the modification and enrichment of content in specific subject areas. This approach assumed that talent in specific subjects could be identified. Students were to be identified early and either placed in special schools for the gifted or enrolled in special programs. Nowhere was this more evident than in gifted education focused on maths and science. Thanks to the technical orientation of the educational system in general, gifted education in maths and science exemplified the best of specialized education within the Soviet system. Russia established numerous schools for gifted mathematicians; some of the leading ones are well-known both nationally and internationally. Among these are Moscow School No. 57, Saint Petersburg School No. 239, Moscow Boarding School No. 18 (now called the Specialized Education-Research Center of Moscow State University), and the Novosibirsk School for Gifted Children in mathematics (now called the Specialized Education-Research Center of Novosibirsk State University).

These four schools have much in common. Selection for admission is based on results from zonal or regional olympiads, summer/winter break maths schools, intellectual competitions by correspondence, entrance exams, and special competitions organized by school staff. Each of these four schools has its own independent curriculum, hires its own staff, ensures compliance of content with national standards, and adopts an individualized approach to students' education as necessary. Each of the schools has established links to top higher-educational institutions, and each offers courses aimed at preparing students for entrance exams, as well as activities that involve young mathematicians in research. Yet, each of these institutions has its own individual profile of strengths, weaknesses, and priorities. For example, graduates of Moscow School No. 57 and Saint-Petersburg School No. 239 have excellent track records in international competitions, whereas the other two schools (the university schools) are known for developing outstanding research skills in graduates. Graduates of these and other specialized schools have traditionally been channeled into the maths and science departments of quality higher-educational institutions and could later expect to receive job assignments appropriate for their talents. For example, among the graduates of Novosibirsk School for Gifted Children there are 12 members of the Russian Academy of Sciences (the highest academic rank in Russia), 120 Professors in leading universities, and 700 Ph.D.s.

In sum, the framework for traditional gifted education was a natural, high-end extension of the Soviet educational system in general. It was subject-oriented, based on ideas of acceleration and

enrichment, subordinated to societal goals, financially supported by the state, attendant to both identification and training, designed to accommodate different levels of education, and underpinned by a labor market dependent on its products.

### *Train 2: Recent Developments*

More recent developments in the education of the gifted and talented can also best be understood in the context of the larger educational system. Russian education started changing dramatically in the late 1980s and early 1990s. The first main characteristic of this 'brave new world' of education is democratization, which has produced an explosion of different programs and approaches. There are now many different types of schools (such as lyceums and gymnasias) and innovative educational programs. Essentially, the old homogeneous system has broken up into a constellation of different approaches. Today, of the 67,200 schools in Russia, 9,126 (or 13%) are of a new type; 540 (0.8%) are private. This differentiation distinguishes between children of different abilities and of different socio-economic backgrounds. The new system also increasingly assumes that the educational process should be individualized. A. Tikhonov, the Minister of Education of the Russian Federation, has described this trend as "a transition from unified education to varied education." This increasing differentiation, however, has been countered somewhat by federal declarations calling for equal educational opportunity for all.

The second major trend in regular education today is increased interest in education in the humanities, arts, and social sciences and, simultaneously, decreased interest in maths and science education. Under the old system, every student was expected to pay his or her dues studying integrals, Newton's Laws, and so on, but now a significant number of programs minimize, or even abandon, rigorous study of these topics. Under the old system, maths was taught according to a particular system named after Kiselev. Now, however, innovation in maths education is overwhelmingly varied and difficult to describe. But the general tendency has been aptly summarized by Russian mathematician Vladimir Arnold, who warned of the danger of "a decrease of hours of maths education in favor of horse-breeding and macramé." In addition to this departure from the tradition of polytechnic education, the modern Russian system has introduced new fields of study that supplement—and sometimes supplant—teaching the logic of a given subject (such as maths). Instead, students learn the logic of a broader subject area (such as the sciences or the humanities) through interdisciplinary study; such programs are aimed at developing particular thinking skills.

The third distinct characteristic of schooling in Russia today is the lack of financial support given the

educational structure by the federal government. For example, as of December 31, 1997, only 76.1% of the budget allotted by the government for educational expenses for the year was actually distributed to the institutions and programs. The subordinate structures of the Ministry of Education (i.e. schools, higher-educational institutions, educational services, etc.) lack sufficient money for supplies, equipment, activities, renovations, meals, and so on.

Finally, the role of parents has changed. In the past, parents were involved primarily in discussions of disciplinary problems. The system was so stable that school environments did not change much from generation to generation. Parents knew that their children were experiencing very much what the parents themselves had gone through when they were school-children. Parents so familiar with the system did not feel that their own involvement was necessary. Today, however, the school environment has changed radically, and so parents have felt a need to become increasingly involved. At the same time, schools struggling in the face of inadequate federal support have encouraged the active participation of parents who can provide essential goods and services. Increased parental involvement has, however, brought complications—namely, disagreement between parents and teachers about what and how teachers should teach.

All of these general characteristics of Russia's modern educational system have impacted education for the gifted and talented. First, the democratization of schooling has gradually reshaped gifted education. In the middle of the 1980s, the Soviet government began financing specialized educational centers for the gifted. However, a 1990 document, 'The State Program of Identification, Education, and Upbringing of Gifted Children and Youth with Creative Giftedness', objected to the closed nature of gifted education and suggested an alternative in which programs could be made available to all educational institutions across the country. This pronouncement called for the development of both specialized schools and gifted programs for use in regular schools.

The budget reflected this overall shift in emphasis from specialized schools to more inclusive, broad-based gifted instruction. Initially, support was gradually withdrawn from the existing system of specialized schools (which focused on the highly gifted) and invested in new programs designed for the gifted and able. However, due to a severe nationwide budget deficit beginning in the early 1990s, the federal government began withdrawing virtually all financial support from specialized programs. The participation of parents and universities in specialized education has increased, but donations, tuition, and university support cannot begin to make up for the loss created by federal cuts in funding. Budget cuts have impacted both old and new forms of gifted education. However, the old

system has been more severely affected, because it had no time to develop alternative financing, whereas proponents of the new system had sought out creative ways to raise necessary funds from the beginning.

Today, federal support of gifted education is carried out under a federal program called 'Gifted Children'. The program's three-year budget is 20,000,000 rubles (or about 3,500,000 USD). In 1997, a total of 21,400,000 students attended Russian schools. Assuming that 1% of these students are gifted (and this is surely an underestimate), the budget provides the equivalent of no more than 5.45 USD per gifted student per year.

The changing role of parents in education has also affected the system of gifted education. In essence, the 'educational niche' of gifted children in Russia is undergoing change. Schematically, this niche includes four components: the child, the family (including parents and children), the school, and the society at large. The modus operandi of the old system was from top to bottom; the societal component dominated the school component, the family component, and, to a large degree, the individual (child) component. The family's role was primarily to motivate and prepare the child, the child's role was to excel, and the rest of the educational program was accomplished by a merging of the school and the society. In contrast, the new system operates from the bottom up; the family, focused on the child, now serves as both initiator and promoter of gifted education. Now, the state's responsibility is all but gone, while the family component of the educational niche grows in importance. The school component remains in the middle, but the school is essentially being 'sold' by the state to the parents; a transition of power has gone hand-in-hand with this reshaping of the educational niche.

Educational goals for the gifted and talented also have been redefined. Before, the system cultivated special talents because it benefited from them; now, however, the system simply is not able to use these talents, so the traditional motivation for developing them is eroding. The second original aim of gifted education—assuring progress—is also in jeopardy. The federal government is no longer funding technological development. Any innovations that are being made are carried out in the private sector. Most of the old connections between federal scientific and industrial centers have been destroyed and nascent networks in the private sector are not yet fully established. Only the third goal—education for the sake of personal growth—has emerged unscathed; in fact, it has grown in importance; attention at last is being paid to children's overall individual development.

Accordingly, Russia is pursuing two new approaches to gifted education, in addition to continuing the traditional one (focused on the modification and enrichment of the standard curriculum in specific subject areas). These approaches are: (1) the accelera-

tion of education; and (2) the redefinition and restructuring of general goals and specific content.

In the acceleration approach, children with a high level of ability are taught (or teach themselves) the regular school program, but they progress at their own pace. These children often skip classes and graduate from high school much earlier than their peers. Only a few schools in the country have accelerated programs. One such school is Moscow Lyceum No. 1524. The experiences of one student there, Daniil, are typical. At age 9, Daniil began his first year at the lyceum in a regular classroom. However, he was way ahead of his classmates, so he decided to study independently, consulting with teachers when necessary. In his first year at the lyceum, Daniel zoomed through three regular grades. After three years, Daniil graduated from the lyceum at age 12 and was accepted at Moscow State University.

The second new approach to gifted education consists of a redefinition of the goals and content of gifted education. This framework assumes that gifted students do not merely know a lot about a particular subject area; rather, they think and act differently. And so, the theory goes, they need an education that not only fills them with knowledge but also helps them develop, both intellectually and emotionally, into balanced individuals.

Some schools have responded accordingly. Moscow School No. 1624, for example, implemented an interdisciplinary program called Constellation that prioritizes emotional and intellectual growth over content-specific knowledge. This program seeks to supplement the imparting of knowledge with programs that help children master higher-order thinking and bring together different areas of studies. The program first enrolled students in 1988 based on IQ scores. Since then, teachers and psychologists have monitored the subject-specific achievements of these students, who were classified into three groups depending on their IQ scores. The jury is still out on the ultimate success of the Constellation program. Notably, however, those in the top IQ tier upon entry have maintained a high level of subject-specific and general achievement. (This is a good sign since, typically, the achievement level of gifted students actually drops upon entry into a specialized school.)

### **Sizing up the Current System**

How can we assess how well the system is performing at this point? We have no hard data that allow us to compare gifted education in Russia with that in other countries. However, we can evaluate the success of Russian education for the gifted based on the results of various competitions. For example, we can, to some degree, estimate the effectiveness of Russia's gifted education in maths and science by analyzing the success of Russian teams in competitions from 1995 to 1997. The most prestigious contests for young

mathematicians and computer scientists are the international subject olympiadas. International competitions are held in maths, physics, biology, ecology, geography, chemistry, and computer science. On average, 70–80 teams of high school students from all over the world attend these competitions.

Twenty-seven Russian teenagers participated in the 1995 competitions. They won 25 medals: 10 gold, 7 silver, and 8 bronze. Russian students won 6 medals in maths and 5 medals in computer science. In 1996, Russia again sent 27 students to the international competitions. Again, the students returned with 25 medals: 11 gold, 7 silver, and 7 bronze. Six were in maths and 4 were in computer science. The following year, 31 Russian students competed in the competitions. This time around, 29 of them earned medals: 9 gold, 12 silver, and 8 bronze. Of these, 6 were in maths and 4 were in computer science. These successes are not specific to the last few years. In fact, this trend of achievement began in the 1960s and has been fairly stable since then.

However, the function of intellectual competitions is changing, and so is their value as indicators of intellectual attainment. In the 'old' system, winners had to rise to the top from the bottom. Individuals had to move systematically up the ladder of competitions from those at the school level to those at the top rung of intellectual achievement. Some exceptions existed; students could enter at different points (e.g. students from specialized schools might join the competition at later stages because their schools could have more than one eligible candidate). In general, however, students progressed from the bottom up, and anyone could start the climb.

In the 'new' system, students use alternative modes of entrance into the system more frequently. For example, of the six Russian winners of the international maths competition held in Toronto in 1995, five were from one St. Petersburg School: School No. 239, for children gifted in maths. This school has an impressive track record of producing winners of international maths and computer science competitions. School No. 239 has developed a special training program with carefully selected teachers to groom students for these competitions. In fact, schools featuring competition-oriented training are on the rise. No longer are the competitions themselves primarily ways to identify talented individuals so that they can then receive appropriate schooling. Now, the young people competing are already receiving specialized schooling. For these individuals, the competitions represent a prize to be achieved 'for the record'. In most cases, having a strong record guarantees acceptance to the better higher-educational institutions.

Some Russian experts have decried this motivational shift, suggesting that teachers be renamed 'trainers' and students be called 'intellectual sportsmen'. In fact, intellectual competition at any but the lowest levels is

turning into a closed system. Children are selected for abilities very specific to these competitions—and then groomed and selected further. At the same time, the olympiada tasks increasingly have a distinctive style; consequently, students can receive focused, competition-specific training. More and more, gaining the skills necessary to solve specific types of olympiada problems is taking precedence over acquiring broad knowledge.

Educators, parents, and experts have noticed these trends. Some educators have responded by developing different ways to identify talent. These avenues are open to children whose 'competitive' skills have not been carefully honed to meet the requirements and time constraints of the olympiadas. One of the most popular of these alternatives is the 'intellectual marathon', which involves competitors in three age groups and three subject domains (maths, human sciences, and natural sciences). It is assumed that these alternative competitions allow for the identification of a wider circle of talented children. Clearly, then, even though success in competitions is impressive, the identification role that these competitions traditionally played has diminished, and the intellectual achievement that these triumphs once indicated is under question.

We also can assess the health of gifted education by observing what happens to talented students after their school years are over. Consider, first, the following general trends in Russian higher education. As of 1997, Russian had 555 federal and 250 non-federal higher-educational institutions (including colleges, universities, technological institutions, and so on.) Collectively, the federal institutions enrolled more than 3,000,000 students, while the non-federal schools served an additional population of 160,000 students. In 1997, there were 220 students per 10,000 people; 174 of these attended federal institutions, and 46 attended nonfederal schools. Russian higher education experienced a dramatic drop in enrollment in 1991–1992. Since 1993, however, the situation has been stabilizing, with an incremental growth in enrollment of 5% between 1995 and 1996, and a 77% growth rate between 1996 and 1997. (Interestingly enough, increased enrollment has occurred primarily in non-federal institutions.) Yet, the enrollment rates of 1997 have still not reached those of 1989.

It is also important to understand that Russian higher education is subject-specific. When students enter a university, they choose a specific subject of study and apply to the appropriate department by entrance exam. Applicants must apply in person. With the exception of a few highly competitive schools (such as Moscow State University), each applicant can typically apply to only one institution per year. (At Moscow State University, the entrance exam is held one month before the exams at the other institutions, so applicants who are not accepted have the opportunity to apply to a different institution that same year.)

How, then, have gifted students fared in this broader picture of higher education? Most graduates of gifted programs in maths apply to the best departments in maths, computer science, and economics. Preferred institutions include Moscow State University, Moscow Physics and Technology University, and Novosibirsk University. These institutions have special programs—and sometimes special departments—to prepare gifted children for entrance examinations. Such school-university partnerships serve both types of institutions: schools and programs for gifted children establish links with institutions of higher education in order to ensure acceptance of graduates, and higher educational institutions forge bonds with schools in order to ensure that the best students will eventually apply and enroll.

For example, statistics for School No. 18 (a specialized boarding school for gifted children in mathematics, established as a part of Moscow State University's Department of Math and Mechanics) graduates are supportive of these practices. This school enrolls 250–300 students from all over the country every year. The typical program lasts three years, but some students join for only a year or two. In 1997, 100% of School No. 18 graduates were accepted by highly prestigious higher-educational institutions. In 1998, the figure was 98%.

Here—at the moment of enrollment in higher-educational institutions—our formal data about gifted graduates ends. Observations from professors tell us little; gifted students are initially ahead of their peers, but this discrepancy, in most cases, is overcome by the second or third year of higher education.

### **The Track Ahead: Challenges for the Future**

Still, we know enough to realize that the challenges confronting Russia's program of gifted education are many and various. Three major issues that deserve special mention here are the funding of gifted education, the reeducation of teachers, the establishment of theory-based instruction, and the harnessing of talents.

First, as federal support for gifted education has diminished, the need for alternative sources of funding has become pressing. Yet the list of potential donors is small. Tax law does not stimulate non-profit sponsorship, and so the funding of schools and programs is left first to parents, then to the potential 'consumers' of 'brainpower' (universities, banks, and high-tech corporations), and finally to alumni. But none of these potential supporters will fund Russian gifted education for the sake of its original primary goal: the benefit of the country. The current financial situation, then, requires a restructuring of the goals of this system of education. Now, gifted education must be aimed, first, at the good of the child (which can motivate parental support), then at the promotion of technological progress (which should draw the support of the 'consumers' of talent), and, lastly, at the well-being of

the country (which should stimulate some federal support—however small it may be).

Second, the training of teachers for the gifted must be refashioned to suit the changing needs and desires of the student population. Traditionally, gifted students have been educated by 'subject professionals': researchers or professors who were experts in particular subjects, but not necessarily in child and adolescent psychology and pedagogy. Moreover, the overwhelming majority of these instructors had no special training focused on the education of the gifted. An emphasis on content knowledge so dominated gifted education that these deficiencies did not matter much. But, in a system that stresses the balanced development of the talented, knowledge of psychology and teaching is crucial. The new system can survive only if it reeducates its teachers. What they know already about teaching their specific subjects is useful and should be retained, but additional teaching and mentoring skills must be developed as well.

One telling 1997 study of educators and gifted children found that gifted children want their teachers to be creative and to allow students to be creative as well. Teachers, on the other hand, did not prioritize creativity when they described either ideal teachers or ideal students. If the expectations of children and adults cannot be merged, the new system of gifted education, targeted primarily at meeting the needs of students, will not thrive.

Third, greater effort should be made to ground gifted education on a solid theoretical basis. Traditionally, Russian gifted education was essentially atheoretical, even though Soviet and Russian psychologists have developed theories covering a wide range of relevant topics—from the role of intuition in giftedness, to the nonlinear nature of the development of giftedness. In general, theoretical work has concluded that giftedness involves cognitive motivation, creative inquisitiveness, an ability to arrive at original solutions, an ability to anticipate and make prognoses, and an ability to create standards of performance meeting high aesthetic, moral, and intellectual criteria.

Along with these general concepts of giftedness, additional theories more specifically address the concept of the gifted child. For example, Nikolai Leites argues that the variability of giftedness must be taken into account. He suggests three different categories of gifted children: (1) children with accelerated intellectual development—those characterized by amazing intellectual activity and insatiable cognitive motivation; (2) children with early mental specialization—those who may have an average level of intelligence and even confront difficulty in some subject areas but who have a predisposition to high achievement in a specific domain; and (3) children who perform exceptionally well in a number of domains.

Clearly, the spectrum of possible theoretical approaches to giftedness is extensive. However, few

ways of thinking about giftedness have been verified empirically in school settings. Psychologists penetrated school systems in the late 1980s and early 1990s and, in the process, established some experimental programs in gifted education. However, programs have not been evaluated formally so that they can be either recommended or ruled out.

The latest programmatic documents of the Russian federal government and the Ministry of Education consistently reveal a new federal push for the theory-based identification and education of the gifted. While this call for theory has some merit, we must be wary of too hastily seizing and promoting one dominant theoretical approach. Right now, there are three possible developments: (1) the new system could adopt multiple theoretical approaches and, at the same time, develop a system to compare and verify their effectiveness; (2) the system could adopt a single theoretical paradigm and test it empirically; or (3) the system could remain essentially atheoretical. The second choice would likely lead to a confrontation between the federal government and the extant variety of approaches to giftedness. And the third option would weaken federal authority in the increasingly theoretical field of gifted education. The first option, it seems, is the best; this path would allow the federal government to replace its unified but atheoretical program with a theory-based program that allows verification of different approaches.

Finally, Russia needs to find ways to harness the developed brainpower that emerges from gifted education programs. In the old system, the Soviet government ensured not only the nurturing but also the consumption of natural gifts. Presently, however, the government cannot pay those it already employs; hiring new talent is out of the question. Thus, one of the most urgent problems facing gifted education today is not education so much as it is productive use of talents once they are developed.

This problem is closely linked to current conditions in the Russian scientific community. Prior to about 1989, approximately 80% of the graduates of the old system became academic scientists in Russia. The situation today suggests the extent of recent change. For instance, about 10% of the 300 1992 graduates of Moscow School No. 18 are working and studying abroad, whereas less than 5% are pursuing academic careers in Russia. A significant portion of the class of 1992 entered the private sector of Russia's developing economy; other graduates simply left no record of their pursuits. For better or worse, graduates of specialized schools and programs for gifted children are entering a much-changed world of work.

What should be done in light of this fundamental shift? Presently, the system produces many gifted young people whose talents are not utilized by today's Russian society. The old system could ignore students' social and emotional development in part because it

protected them when they entered the working world. To be fair to its students, the new system should equip those growing up today with survival skills. There are now fewer guarantees in the adult world than there used to be.

In sum, Russian experts have proposed three immediate actions: (1) the development of diverse models of gifted education including expert validation prior to implementation, (2) the promotion of investment in gifted education, with careful oversight, and (3) the development of a theoretical model of gifted education that allows for a diversity of approaches but incorporates hard-won, traditional knowledge.

In gifted education in Russia today, old traditions and new developments coexist in the dynamic context of a society undergoing profound transformation. Still, the system functions. In fact, at the superficial level of success in international competition and higher education admission, it functions no less well than in the past. The residual stability of the traditional system (train 1) and the acceleration of the new (train 2) coexist and keep gifted education rolling along. But soon the old system will not be effective at all; already its vital signs are dwindling. In a best-case scenario, the new system will inherit the best of the old ways and move on, while the old system will willingly allow some of its components to be altered to fit the new context. All of us concerned—educators, parents, policy-makers, and social scientists—must work to ensure that this inevitable integration will be as harmonious and productive as possible.

# Middle East Region: Efforts, Policies, Programs and Issues

Taisir Subhi<sup>1</sup> and Netta Maoz<sup>2</sup>

## Introduction

The purpose of this chapter is to provide an explanation of the provisions for gifted and talented children in the Middle East including the Arabic countries and Israel. Because we are dealing with issues that have such important consequences for resource allocation and for the future of children in the region, it is important to look critically at the present situation and future trends in the region. This chapter concerns itself with practices, and current thinking on a number of major issues in the area of identification and the development of giftedness and creativity.

## The Arabic Countries

In the Middle East, like other developing regions, gifted children are important to the modernization of society. About 50% of the population is under fifteen, every third person is a student, and the region's governments spend about 8% of its annual budget on education. Skills are among the region's chief exports.

School is organized around three cycles: elementary (6–12 year olds), preparatory (13–15 year olds), and secondary (16–19 year olds). The first two cycles are compulsory for all boys and girls. All schools follow the curriculum laid down by the Ministry of Education, and Arabic is the medium of instruction. In elementary school children learn Arabic, religion, mathematics, geography, science, drawing (for boys), embroidery (for girls), music, drama, and physical education. Starting from the fifth grade, all children learn English as their second language.

The preparatory cycle was added in the 1960s, providing children with an education designed to prepare them for secondary education or the labor market. This cycle is seen as enabling students to develop scientific thinking; to form positive notions

about life and society; to have respect for truth, discipline, and work; and to recognize their rights and responsibilities. Those students who pursue the secondary cycle take the General Secondary Examination (Tawjihi) at the end of the cycle. Arabic is the medium of instruction and English is a compulsory subject.

All teacher training in the Arabic countries is conducted at the post-secondary level in teachers' colleges that offer special diplomas and have demonstration schools attached to them. As of 1998, 74.9% of academic and vocational secondary school teachers were untrained, but an increasing number of teachers are attending two-year part-time postgraduate diploma courses in education offered by universities. The universities now also offer courses for a B.Ed. degree.

Although many educational bodies in the Arabic countries are responsible for minor aspects of education, the Ministry of Education in every Arabic country maintains centralized control of all education other than in the universities. The Ministry recruits all teachers to state schools through the Civil Service Commission, administers the General Secondary Examination (Tawjihi), and provides all educational resources including textbooks, prepared centrally, which are given out free of charge to children in the compulsory cycle and at cost to students in the secondary cycle. In recent years, however, the Ministry of Education in each country has taken a number of steps to decentralize control. For example, it now delegates responsibility for implementing Ministry decisions with regard to staffing, scholarships, and building.

## *The Educational Process: Aims and Philosophy*

The aims of the educational process in the Arabic countries were formally set out in the 1960s and were derived from a variety of sources. These sources reflect the diverse strands in the region's historical development including their Arabic Islamic heritage, British and French influences, and aspirations towards international standards of education and modernization. Prior to the 1960s, education was based on the Arabic

<sup>1</sup> Al al-Bayt University in Amman, Jordan.

netta.maoz@weizmann.ac.il

Islamic heritage and a view of knowledge inherited from the British and the French. This philosophy emphasized cognitive development. Its purpose was to develop the mental ability of children, but it did not take into account the development of the whole person or the needs of the society. The old aims of education concentrated on inculcating knowledge, facts, and information. Students learned by heart the subject matter, which often did not link with their daily lives. This means that there has been a shift from knowledge-centered aims to child and society-centered aims.

A new philosophy and new aims for education were introduced in the 1960s. They reflect the influence of international developments in education and broader aims for the education systems in the region. The problem has become whether the new philosophy and its associated aims of education can be realized in practice by societies that possess traditional attitudes towards education.

Article 4 of the 1964 Jordanian Education Act, for example, sets out a detailed set of curriculum aims [translated from Arabic Text]:

- (1) To prepare the righteous citizen who believes in the following:
  - (a) The principles of educational philosophy in Jordan; while drawing on the basic ingredients of Arab Islamic heritage a certain amount of emphasis is placed upon the possibility of modernization.
  - (b) The rights and responsibilities of citizenship.
  - (c) The practical realization of ethical ideals whether collectively or by individuals.
  - (d) Initiative in work and in behaviour, fruitful cooperation with others and the application of democratic principles in human relations.
- (2) Understanding the environment including its natural, social, and cultural forms, beginning in the family home to school, village, city, district, or country (Jordan), Arab home, and human society, provided that it is accompanied by the following:
  - (a) An analytical understanding of all the features, varied problems, and current and future needs of the environment.
  - (b) It should be achieved in such a way that it develops positive feelings in the individual concerning his/her duties for participation in the development of the environment, in accordance with his/ her aptitude and his/her ability.
- (3) To develop basic skills such as:
  - (a) Calculation and communication such as speaking, hearing, reading and writing standard Arabic, and enjoying reading and increasing knowledge.
  - (b) To pursue the scientific method in research, thinking, inference, and to make distinctions between right and wrong.

- (c) To adjust, achieve, change, develop and progress and to minimize boredom, confusion, and frustration.
- (4) To provide students with an educational environment that will provide the greatest possible development of their abilities.
- (5) To promote collective and individual health by disseminating health information and the development of healthy habits.
- (6) To promote collective and individual recreation by developing habits of healthy recreation and varied features of Arab and Jordanian Folk Art.
- (7) To promote collective and individual economic advancement, and to increase the national income, by providing educational opportunities for all, by the diversification of educational programs which meet the interests and desires of individuals on the one hand, and on the other hand, satisfy the future and present needs of Jordan in all fields within a comprehensive economic blueprint of the State (Ministry of Planning, 1990).

The aims are general and vague, and not sufficiently defined to permit easy translation into curriculum objectives or instructional materials, making it difficult to institutionalize them and realize them adequately in practice. In brief, the aims do not show where and how they could fit into the general philosophy of education for these countries. Neither does it show how they can be used to develop specific curriculum measures.

#### *The Character of the Educational Process*

The Arabic countries face a number of problems and challenges in relation to education in general and gifted education in particular. Problems vary in complexity and magnitude from state to state. The First Conference for Education Development (1987) which took place in Jordan summarized the weaknesses of the Arabic educational process as follows:

- (1) The region suffered from educational neglect during many centuries of foreign domination. During the earlier years of this century, efforts were directed primarily toward expansion of available resources and little attention was paid to quality.
- (2) The region is still far from providing sufficient facilities for all school-age males and females.
- (3) Among the most serious problems which reduce the efficiency and increase the real cost of education are excessively high dropout and repetition rates in all education cycles.
- (4) Teachers making suitable provisions for gifted and talented students are not always appreciated.
- (5) Lack of ability and interest in creating a supportive environment essential for nurturing gifts and talents.

- (6) Lack of opportunities for participation by students in the discussion of educational and social issues of concern to them.
- (7) Lack of interest on the part of males in joining the teaching profession, coupled with a high turnover rate due to a variety of moral, material, professional, and social causes.
- (8) Shortage of qualified teachers in academic and vocational secondary schools.

Change and innovation have always been a vital part of human existence, yet only in the recent past has the process of change been transformed into a worldwide revolution. This revolution originated in Western Europe, but the process of modernization has become an increasingly universal experience. In one Arabic country after another, the transformation of traditional society and culture has taken place, though at varying speeds and in different ways (Subhi, 1997). Schools are viewed as instruments of change, and maxims about this are frequently encountered in the speeches of Arab officials (Szyliowics, 1973; Al-Tal, 1979).

Before the fourteenth century, the Middle East enjoyed a civilization which endured for more than five hundred years, and witnessed intellectual, artistic, scientific, and cultural achievements that influenced world culture (Huxley, 1963; Sa'ab, 1980). Yet, in the end this rich culture withered, and the high achievements of the Arabs in science, literature, medicine, and fine arts became dim memories (Al-Tal, 1979). One of the reasons for this decline was the failure of the education process to respond to changing demands, including production of gifted and talented scholars, statesmen, and administrators.

Practically every country is seeking to achieve a rapid rate of economic growth. Underlying the huge investment being made in education is the belief that schooling is a major variable determining the level of economic development. In general, researchers have concluded that positive relationships do exist between the formation of human capital – in which education is a major component – and economic growth. Experts have calculated that much of the rise in income in the U.S.A. between 1900 and 1956 was due to improvements in workers' educational qualifications. The (former) U.S.S.R. and Japan are often cited as further evidence of this relationship. All three countries possessed highly developed educational processes, and a significant proportion of their population was literate before the economy began to undergo rapid development (Szyliowics, 1973; Sa'ab, 1980).

#### *Provisions for Gifted Children in the Arabic Countries*

Changing philosophies and goals, economic priorities, and what we know about gifted children suggest a number of aims for gifted education in the Arabic countries including: developing an efficient and comprehensive procedure for identifying gifted and

talented students in school as early as possible; providing gifted and talented students with an educational environment that enhances their abilities; developing problem solving abilities and creative thinking skills, research skills, individual interests, independent study skills, communication skills in the humanities (visual, oral, and written), and intellectual learning activities. Problem formulation abilities are also very valuable in all endeavors.

An appropriate curriculum is crucial to gifted education, and some instructional strategies may be more efficient than others in delivering the appropriate content to gifted students (Fox, 1981). Renzulli (1980) noticed that gifted programs are too often patchwork collections of random practices and activities; he suggested that differentiated programs for the gifted must include modification of the ways in which advanced materials are presented. Because we are dealing with an issue that has such important consequences for resource allocation and for the future of children, it is important to look critically at the nature of the process involved in identifying gifted and talented children and provide them with special provision and programs to meet their special needs.

#### *The Multiple Criteria Identification Processes*

According to Hallahan and Kauffman (1981):

People who are gifted, or at least have the potential for giftedness, can go through life almost totally unrecognized for their talents. Sometimes the gifted go undiscovered because their families and intimates simply place no particular value on their special abilities. Sometimes they are not recognized because they are not given the opportunities or training necessary to show what they can do. Especially in the case of children who are poor or members of minority groups, the gifted may be deprived of chances to demonstrate and develop their potential. How many more outstanding artists and scientists would we have if every child had the opportunity and the training necessary to develop his or her talents to the fullest possible extent? There is no way of knowing, but it is safe to say we would have more (p. 434).

Gifted children are identified in this region as those who have demonstrated high ability (including high intelligence), high creativity, and high task commitment. In addition, three Arabic countries including Jordan, Bahrain, and Egypt have added achievement (e.g. in mathematics) as the fourth criterion. In the adopted definition, standardized intelligence tests, creativity tests, and achievement tests measure abilities. Task commitment is measured by tests of

achievement, rating scales, and judgment of teachers and parents.

The multiple criteria identification procedure adopted by the Arabic countries, is based on a number of principles (or rationales), including:

- (1) gifted and talented children should be identified as early as possible in their educational careers;
- (2) the focus of identification is not to label students, but to recognize and respond to gifted and talented students' educational needs;
- (3) the identification of gifted and talented students requires the utilization of formal and informal measures obtained from many sources in a wide variety of settings; and
- (4) identification instruments and procedures must match with the program provided to gifted and talented children.

The major purpose of a multiple criteria identification process is to determine which children have a need for special educational provision, whether as a supplement or as an alternative to regular mainstream instruction, and to pinpoint or diagnose their special needs (Subhi, 1992). The multiple criteria identification process should be flexible and inclusive rather than exclusive (Feldhusen & Wyman, 1980).

#### *Alternative Models of Provision*

Included in the very broad spectrum of forms of special provision for the gifted and talented are acceleration and enrichment, and it is increasingly being recognized that they are best seen as complementary. A number of acceleration models are in place such as grade skipping in Bahrain, Iraq, Jordan, Qatar, and Kuwait; and grade or advancement placement in single subjects in Egypt, Morocco, and Lebanon. Other special provisions include grouping within the ordinary class, special schools and special classes, provision of resource rooms, extra courses, and similar measures. Provision outside the traditional school has also been reported, such as through competition, summer camps, and mentoring programs (Urban, 1993). Private groups, such as the National Association for Gifted Children, support family emotional needs, offer summer schools, and promote the children's interests to the public. New enrichment materials have been produced, and a number of workshops were conducted in the region.

Survey studies conducted in the region (Subhi, 1997) indicated that the most common form of provision for gifted children at the primary level is to leave their normal classes for a resource room or computer lab with a specially trained teacher. This is followed by self-contained classes. At the secondary level, grade skipping, special classes, and independent studies were applied most often. In addition, mathematically gifted students profit by participating in accelerated mathematics programs.

#### *Enrichment*

Gifted children need greater pace, breadth, and depth than most other children. This implies a need to provide all kinds of provisions which enrich the normal academic curriculum (Urban, 1993). It is clear that enrichment should give opportunity for creative production and expression of ideas and training of general strategies or techniques of study, which can then be applied to intellectual work in general.

In Arabic countries, three enrichment programs are provided for children from grade three up to grade twelve. These programs are conducted on a part time withdrawal basis one morning or afternoon per week. The Enrichment Triad Model (Renzulli, 1977) has been implemented in a large number of private schools in Jordan, the West Bank, and Bahrain. Resource rooms, as a special provision for gifted and talented children, are used in several Arabic countries. In special room(s) within the school building students work independently or are guided by a special resource teacher on freely chosen or assigned projects. These rooms include books and other publications; electronic, audiovisual equipment, and computer hardware; computer software; CAL packages; word processing, spread sheets, and data bases; instruments and apparatus for work in the sciences, materials and requisites for art and music, etc. (Urban, 1993). We must however take into consideration that the effective and efficient use of the resource room(s) in other Arabic countries depends on the availability of the trained and experienced resource teacher.

#### *Problem Solving*

In our rapidly changing world, the need for critical and creative problem solving is crucial. The question arises as to whether or not we can teach children to think creatively. The task, however, is to find realistic ways to implement programs which develop thinking skills in the classroom (McCluskey & Walker, 1991). Problem solving sessions, activities, and programs are available in a large number of schools in the Arabic countries. Both public and private schools provide educational experiences that use a set of problem solving strategies, such as looking for a pattern, making a list, guessing and testing; searching randomly, setting up a question, and working backward.

In Lebanon, Dr. Iman Osta and her colleagues have established a new agenda for teaching mathematics as an active process of discovery and inquiry. Talented maths students are provided with curricular opportunities, provisions, and classroom practices to experience the delights of mathematical communication, reasoning, creative thinking, and creative problem solving.

In the West Bank, for the last forty years, the Palestinian educational system continues in the traditional form, where the schools' staff has never had the chance to be exposed to new approaches and has never received training. As a result, no provisions are

available to meet the special needs of gifted and talented students. The majority of children do not even have the chance to practice thinking skills. During the next decade, the main focus should be on using different approaches to provide students with opportunities to explore and experience logical, critical, analytical, and creative thinking derived from their own social environment.

#### *Individualized Educational Programs (IEPs)*

The IEPs can range from independent study activities planned to supplement, extend, or substitute classroom work for gifted and talented students to the formalized long term planning IEPs involving adaptation of the content, the process, the product, and the learning environment. The individualized instruction is diagnostic and prescriptive. The prescription is cooperatively developed by both the teacher and the gifted student, and can include information from different sources. Self-direction and self-selection of topics are key aspects in an individualized program. Up to now there are no IEPs being implemented in the Arabic countries. Further research needs to focus on this type of special provision and investigate how we could employ such provision effectively and efficiently.

#### *Grade Skipping*

It is now becoming possible for gifted and talented students in Bahrain, Egypt, Iraq, Jordan, Kuwait, Qatar, Lebanon and Morocco to 'skip grades'. After decades of neglect, giftedness and creativity are receiving more attention in Kuwait. It is for this reason that little attention has been paid to grade skipping there. Very limited numbers of schools include creative activities as an instructional strategy for reaching all children.

In Morocco the Ministry of Education has established a National Committee for Gifted and Talented. Scholars and interested people are planning to form a law to enforce consideration of gifted children in education. In addition, a national association for the gifted will be formed. However, little attention has been paid to grade skipping yet in Morocco.

#### *Friday and Summer Programs*

In Jordan, Bahrain, United Arab Emirates, and Egypt, special Friday courses constitute one of the main services provided for gifted children. Many different topics are offered for pupils in grades 6–8 (e.g. computer science, journalism, archeology, space and astronomy, philosophy). Privately organized Friday morning or after-school classes for special tuition are common in a number of Arabic countries, including those designed to foster cultural traditions and languages.

In both Syria and Lebanon there are still no official definitions of either giftedness or creativity nor public policy for educating gifted and talented children.

Currently, there are a few special programs for gifted students offered in individual schools, in clusters of schools, or run as private enterprises mainly after-school or on Friday or Sunday. These centers offer students opportunities to interact with and be stimulated by other gifted and talented students. From time to time (not on a regular basis) there is a special workshop or field trip organized by private schools.

#### *Competition*

Freeman (1990) pointed out that competition can be a strategic way of finding and defining children's capabilities, whether compared to others or to his/her own best performance. She added: "Many highly able children used [competition] quite consciously to improve their skills, because of the reward it offered them. But they knew that in order to be effective, the comparison had to be meaningful, as well as part of the process of getting to the top, which is not the same as the simple thrill of winning" (pp. 93–94). During the last decades, competitions have become very popular in many countries in the region; the number of participants in international competitions or educational Olympiads has greatly increased. International, national, and regional competitions may be valuable assessments of and incentives for achievement. Further, competitions may provide feedback as to how the student compares with others who are interested in the same area. Regional and national competitions can be found in Arabic countries in most fields, including maths, science, computer programming, writing, engineering, geography, environmental, art, music, and dance.

#### *Special Schools*

The Jubilee School Project was first announced in 1977 during Jordan's celebrations of the late King Hussein's accession to the throne. The School is a tribute to His Majesty's development efforts, especially in the field of education. In 1984, Queen Noor accepted a request by the Prime Minister to assume responsibility for the project, and in 1985, when the Noor Al Hussein Foundation was established, the Jubilee School became one of its projects.

After years of research, planning, and teacher training, the Jubilee School was founded as an independent coeducational secondary school for outstanding scholarship students. In the Fall of 1993, 87 Jordanian ninth graders, chosen for their exceptional individual and academic potential embarked on a pioneering educational experience. The School expanded the following year to include 197 ninth and tenth graders. A rigorous multiple-criteria system is used for selecting Jubilee School students that includes school achievement over the last five semesters, ratings of behavioral characteristics, general mental ability, specific mathematical ability, and creativity level.

On May 2, 1995, on the 42nd anniversary of his assumption of the throne, the late King Hussein laid the foundation stone for the first phase of the construction of the Jubilee School campus near Amman. In addition to boarding facilities, which enables the School to welcome a larger number of students from remote areas of the kingdom and to open its doors to students from the rest of the Arab world, the campus also includes a comprehensive library providing access to databases worldwide, modern computer and language laboratories, vocational and teacher training centers, a music and drama center, and athletic facilities.

The Jubilee School reflects a Noor Al-Hussein Foundation's philosophy that is sensitive to traditional values and responsive to the needs, talents, and aspirations of the people of Jordan. As with other Foundation projects, the School's innovative approach to education encourages initiative and democratic participation, while contributing to national education standards.

The Jubilee School provides educational opportunities for gifted and talented students, with a special emphasis on students from less developed areas of the country. Convinced that gifted and talented students represent a national wealth that should be carefully nurtured, the School seeks to develop future leaders committed to the service of their country and capable of addressing the constantly changing challenges of our region and the world.

Beside the basic requirements of the Jordanian Ministry of Education, Jubilee School students are required to take courses especially designed to develop their critical thinking, problem solving, investigative, creative and decision-making abilities. The School is the only educational institution in Jordan presently linked to the Internet, facilitating interaction with schools, institutes, and databases worldwide. In addition to rigorous training in mathematics, science, and the humanities, the Jubilee School students are also required to choose from subjects such as advanced calculus, advanced physics, astronomy, computer graphics, debate, drama, economics, human genetics, journalism, literary criticism, and world history.

The Jubilee School is committed not only to equip its students with a strong academic base, but also to build character and a sense of social responsibility through two programs. The Leadership Guest Speakers Program introduces students to successful leaders in various fields, and fosters open discussion and debate designed to help students develop their own leadership qualities and self-esteem. The second, the Community Service Program, requires all students to participate in community service projects.

The Jubilee School also sponsors the Center for Excellence in Education, established in 1999 to develop and disseminate knowledge of innovative approaches and advances in mathematics, science and the humanities. The Center has become a resource for

secondary school teachers in Jordan, where curriculum modules which successfully integrate these disciplines are currently being developed. Deeply committed to a democratic learning environment, the School encourages freedom of thought and expression. Further, as a center for excellence in education, one of the School's primary functions is to provide a variety of educational services to public and private institutions through workshops and training programs for staff and faculty. The Counseling and Career Center was established to provide personal and career guidance to students and to address their emotional and social needs. Counseling programs are also held for the benefit of teachers and counselors from across Jordan and other countries. The Jubilee School students will also be able to sit for external examinations, including the SAT, TOEFL and GRE. A special advanced placement program is being studied whereby students can earn university credits for advanced courses in science, mathematics, computer science, and literature. The School also plans to develop an Educational Testing Service (ETS)-like organization in Jordan. Instruments similar to the SAT are currently being developed to be used as admission tests to the Jubilee School and local universities.

In Egypt, the first school for high achievers was established in 1955. Eleven years later, more programs designed and special classes were founded. These programs were established in recognition of the special educational needs of gifted and talented children. Egypt is a country with a long tradition of respect for education and high standards at all levels. Special classes are comprised of intellectually gifted children, although on the whole, the formation of special classes is not a policy used extensively in the Arabic countries, especially at primary school level. The argument used against special schools or special classes are that they promote elitism, prevent gifted children from learning to interact with their age peers, and prevent other children from benefiting from their presence.

In Saudi Arabia, research was conducted to describe the most effective approach for identifying gifted and talented children. In addition, the Ministry of Education has established a new foundation to support projects designed to meet the needs of gifted and talented children and serve the country's population of gifted and talented students. The Foundation will establish high schools for gifted youth, enrichment programs as well as other projects of merit.

#### *Mentorship Programs*

Mentor Connection is a new, three-week, residential summer program held at the Jubilee School for national and international young people entering the last two years of their high school experience. The program provides opportunities to participate in creative projects and investigations under the supervision of university mentors. Each year, accomplished university professors and graduate students work side-by-side

with students on research projects, productions, and other works-in-progress in shared areas of interest. Students and mentors become a community of scholars of all ages working together on important problems that are on the cutting edge in the arts and sciences.

Mentor Connection students have the opportunity to participate in a variety of other experiences in addition to their preselected mentorship. Young people attend workshops designed to teach them about computer technology, and state-of-the-art electronic data retrieval systems. Program participants enter the real world of research; engage in hands-on, high-level learning; and emerge from the program with new visions of who they might become. This program allows students to achieve to their highest potential by participating in experiential research projects that provide direct, apprentice-based involvement with faculty members who are conducting research in their respective disciplines.

#### *Computerized Provision for Gifted Children*

Pelgrum & Plomp (1991) argued that many countries throughout the world are facing serious questions about the role of computers in education: what is the place and role of computers in the schools? How can the computer be used effectively in existing subjects? What will be the effect of computers on students' learning, on teachers' behaviour, on the school and classroom organization? Hawkrigge et al. (1990) reported that in developed countries, computers were used for four main purposes:

- (1) To become aware of the uses and limitations of computers.
- (2) To learn computer programming.
- (3) To learn the correct uses of application programs, which are sometimes called productivity tools because they have the potential to increase productivity.
- (4) To learn selected topics from school subjects (p. 15).

Children in developed countries easily master use of keyboards, and understand texts and pictures on a computer screen more readily than students in developing countries. Blease & Cohen (1990) pointed out that "a familiarity with the potential of the new technology leads us to newer, quicker, and more efficient ways of doing things and, in some cases, to a realization that we are now able to accomplish what previously was totally beyond our grasp. In the classroom context this is particularly true of such things as simulation, word processing, desktop publishing and data bases" (p. 1). Many reasons have been presented for introducing computers in education. Hawkrigge et al. (1990) summarize these reasons in terms of six rationales. First, a social rationale: to equip all students for a future in which technological awareness and basic computer skills will be necessary. This implies that

individuals should follow courses on computer awareness. Second, a vocational rationale: to build a resource-base of people skilled in information technology. Computer education should be related to future jobs, and individuals should be prepared to function adequately as professional workers in a technological society. Third, a pedagogical rationale: to use new technology to enrich the existing curriculum and improve instructional processes and learning outcomes. Fourth, a catalytic rationale: to promote changes in education by moving towards a more relevant curriculum and by bringing educational opportunities to a larger number of people. Fifth, an information technology rationale: to stimulate the national computer industry by governmental expenditure on large numbers of nationally produced or nationally assembled computers in the schools. Finally a cost effectiveness rationale which argues that computers can reduce the overall cost of education. In the context of Jordan and other Arabic countries, one might distinguish another rationale, namely, the opportunistic rationale: the expectation that the use of computers in private schools may contribute to attracting more students to those schools. However, if there is no explicit policy, computers are used in an uncoordinated fashion. Teachers are not trained, software is scarce, and hardware is incompatible, and spares, repairs, and maintenance hardly exist (Hawkrigge et al., 1990).

A mixed picture emerges from a survey conducted in this region (Subhi, 1997). While computers are quite widely used in schools, they are thinly distributed and few teachers have training in their use. There are problems with availability of software and the most frequent educational use of computers is for drill and practice rather than for developing cognitive ability through problem solving and open-ended computer programs. This implies that the most worthwhile use of computers in schools lies with more innovative software. When we start to consider cognitive development to be of more central interest, and place children in the most appropriate educational settings, then we can see impressive achievements through the use of innovative software (e.g. open-ended simulation, Logo, problem solving, spread sheets, data bases, productivity software, etc.). If the Arabic countries are to achieve the potential of the computer which led Papert (1980) to anticipate an educational revolution, then they need to optimize the use of computers in the Arabic schools and to overcome the obstacles mentioned previously. In other words, real innovation can only take place when good quality software products are available in both Arabic and English languages, and teachers are well acquainted with these products by being trained in using them and integrating them into their instructional approaches.

If computerized problem solving is to be the focus of the mathematics curriculum, then it must also be given a place in teacher training programs. In other words,

we must make effective and efficient use of what we know about how gifted children become problem solvers to design training programs for teachers. In addition, this implies requiring a course in computerized problem solving for all mathematics teachers. Teachers working with computer programming should be aware of the ideas gifted and talented children are forming and assist them in improving their performance and developing their mathematical skills. Yet, there are still many debates on how and how much the computerized programming environment can enhance schooling outcomes, and how this computer environment can provide special provision for gifted and talented children. There are no recent Arabic or cross-cultural large scale studies on the impact of computerized programming environment on children's achievement and creativity (Subhi, 1999).

Some obstacles exist to greater and better computer utilization. Computers must be purchased, software must be selected, facilities must be prepared, and then a curriculum has to be written for the inclusion of computers. Once these steps have been taken, staff development must proceed and, finally, teachers must change the way they teach. We must not expect effective use of computers to be developed in a year or even two. But with careful long-range planning, a computer-enhanced learning environment can be established in order to improve the teaching/ learning process.

The need to keep accurate records of the abilities that children display has been clearly demonstrated. In the absence of these records, teachers' memory of specific abilities seems to fade, so judgments based on memory alone are likely to be based on overall and unreliable impressions. In addition, the effective record keeping we have recommended (Subhi, 1997) should be computerized and used continuously to permit teachers to monitor each student's progress. The computer software we have developed and designed (Subhi, 1997) could play a major role in proposed computerized record keeping. Despite the problems and obstacles, clearly there are benefits to increasing the effective and efficient use of computers in teaching mathematics and other subjects.

#### *The Arab Council*

In 1996, Prof. Joan Freeman, Dr. Taisir Subhi, Dr. Abdul Aziz Kamal, and other Arabic scholars founded the Arab Council for the Gifted and Talented, in Amman, Jordan. The ACGT now represents 13 Arabic countries, including: Bahrain, Egypt, Jordan, Kuwait, Lebanon, Libya, Morocco, Qatar, Saudi Arabia, Syria, Tunisia, United Arab Emirates and the West Bank.

The ACGT aims at providing a network for the exchange of ideas and research findings and results related to teacher training of gifted and talented students among individuals and institutions in the Arabic countries; promoting public awareness of the

exceptional abilities of gifted and talented children; conducting research and providing database and technical facilities to meet the special needs of gifted and talented children.

#### *Recommendations*

In sum, Arabic countries seem to be developing too few special curricular materials for classes and programs and special provision for gifted and talented children. The classroom teacher is expected to design or adapt existing materials despite the fact that gifted education for teachers is not widely available, compared to other areas of special education.

Third World problems in educating gifted and talented children arise from unique political and economic issues. The issues frequently concern the perceived needs of the country, the availability of jobs in the present market, and demographic surveys which reflect the present rather than the future status of the nation's economy, including health problems and population figures. These issues rarely center on the children themselves, on their needs, or on their potential to contribute to a global as well as domestic society (Harris, 1986; Subhi, 1997). In the Arabic countries, the picture of gifted education is far from rosy particularly in the case of a small developing countries like Jordan and Lebanon, which are currently undergoing political, economic, and social upheaval that leaves little time for matters such as providing special provision for gifted and talented children.

In Arabic countries we should not be content to wait for improvement and development to occur spontaneously in teaching gifted and talented children. If we really want to improve our education systems and to meet the special needs of gifted and talented children in our society, it will be necessary for us to take some very direct and deliberate actions. Earlier studies on giftedness did not make use of computers or related forms of educational technology. One of the key considerations in the early stages of our chapter was to determine whether, and how, educational technology could be used to benefit gifted children. More recently, the range of possibilities for using computers and multimedia in education has increased significantly.

One of our beliefs in choosing to carry out research with the gifted was that innovations developed and tested with gifted children might benefit mainstream education. We have anecdotal evidence that this may be the case. It would be good to have the opportunity to test this belief more rigorously, through inclusion of children from mainstream schooling in comparative experiments (using Logo and CAL).

It is important for gifted and talented programs implemented in any developing country to gain notice and recognition, not only within their own borders, but in interchange with others. We suggest establishment of a network that provides a forum of exchange, provides information, support, encouragement, exam-

ples and ideas, to strengthen opportunities for both the gifted and their countries. In addition, the network could branch off into research areas, provide an arena for follow up studies, stimulate planning efforts, provide a way of sharing concerns, serve to illustrate what giftedness means to emerging nations, and promote international awareness.

### The Israeli Experience in Gifted Education

Israel's well-developed educational system was established at the beginning of the century, before the British mandate, and continued with the establishment of the Jewish State in 1948. The school system, like that in the Arabic region, is based on the structure of 6:3:3. Education in the kindergarten through 9th grade (5–15 years) is compulsory, and studies from ages 5 to 18 are free of charge. In areas that absorb many new immigrants, free education starts even earlier at the age of 3. Education is 10% of the annual national budget.

The provision for the gifted by the state began in 1973. It grew out of the 1971 Knesset (Parliament) educational policy and budget, presented by the Minister of Education and Culture. He stated that each child had the right to develop his abilities and that it was the task of the Ministry to provide proper frameworks and content, which would enable such development (Burg, 1988).

Starting from its creation in 1973, the Department for the Gifted began to establish special classes and afternoon workshops. Most of the larger cities and smaller towns have such enrichment programs. At the time, the Department rejected special schools for sociopolitical reasons and opted instead for expanding the after-school enrichment centers. By 1981, more than 5,000 students—an estimated 30–40% of the potentially gifted population—was being served by the centers which were funded on a shared cost basis by parents' tuition, the Ministry of Education, and the local sponsoring agency. These centers focus on mathematics and science including computer-based and laboratory experiences, plus offerings in art, music, literature, history, philosophy, creative writing, and journalism.

The Israeli Ministry of Education carries several delivery systems for its gifted and talented children:

- (1) Dual University enrollment—gifted high school youngsters start their higher education while still in high school.
- (2) Pullout classes in the big cities where every child identified as gifted is served once a week.
- (3) Enrichment programs for gifted school pupils in the universities, mainly in science and mathematics.

In 1996 the Ministry of Education, Culture and Sport decided to adopt a new policy of identification and treatment of gifted children by broadening the definition of giftedness, identifying the gifted and nurturing

them (Rachmel, 1997). According to the new policy, the schools will be responsible for initial identification of their gifted children, and teachers themselves will propose special programs to teach these pupils at the schools. Gifted education in Israel is now in a transition state; identification and treatment are still conducted mainly by the old methods, while the new approach is in the process of being implemented. At the beginning of the academic year 2000/2001 the following changes will be implemented: (a) the identification process will be verified; (b) the high school students in the special classes for gifted education will have an option to get a weekly one-day university education in special centers; (c) special multi-regional centers for weekly enrichment day will be intensified.

### Neglected Resources—The Professionals

Since youth programs in universities and research institutes are relatively rare, these resources are the 'neglected resources' in the education of the gifted and talented.

Science and art museums are most active in extracurricular and informal education. Almost every museum has an education department. These departments offer instruction to two populations: first, to the general public, so that scientific research and the arts become familiar to youngsters who, in the future, may become the decision and policy makers, and second, to gifted and talented children in their areas of interest. Thus, youth develop contacts with professionals and are exposed to resources not otherwise readily available. While art museums do have the appropriate professionals to cater to gifted children in the art domain, the high level personnel suitable for working with gifted children in science are found in the universities and research institutions.

### Extracurricular and Informal Science Education in Israel

Israel offers its young gifted and talented science enthusiasts (4th–12th graders) a nationwide network of science activities based in the universities and research institutions to enhance what is offered by the schools. These activities include science clubs, summer camps, mathematics and science Olympiads, programs in science museums, etc. Most activities are in the life sciences, medicine, exact sciences, computers, mathematics and technology. About 16% of the students who participate take humanities and social science courses. Most programs are offered to students, who enroll on an individual basis, during the afternoons and holidays.

The programs in the universities are offered to two categories of youngsters: (a) Children who were identified as gifted and (b) science-motivated children. One of the most important aspects of the programs for science-motivated children is the 'self selection' approach. The students choose to come to the academic

center, and thus have a very high commitment to participate. These children give up their after-school time, or sometimes their holidays, because they want to join the extracurricular framework. Their parents must pay, at least partially, for the activities and in many cases they have to transport them to the center. The Ministry of Education subsidizes the activities by 20%.

The courses for 7th–12th graders are not necessarily offered to children labeled as ‘gifted’, but to those who are challenged by high level courses; thus, the children are not labeled, but the courses are. The topics are either an enrichment to school curriculum or completely new. Participation in such a course enables the highly intelligent youngster to meet with other children with similar interests; this interaction is of great importance to the children. Some highly intelligent children have few friends in their own neighborhood, while others are not motivated to learn, since they acquire knowledge very easily. When they meet other children like themselves they are able to feel validated and better understand their abilities.

#### *Science Projects*

School students in Israel are encouraged to work on a special independent project, as a substitute for taking a final examination in one of their school subjects. Science projects for credit in physics, chemistry, biology, mathematics, and computers are done at the universities or research institutes. The student works with a mentor in his laboratory on a science project. The work done in this framework is usually related to a real research project being conducted by the scientist. Upon completion, the students summarize and report on their work to the school. Learning from a scientist engaged in high-level research offers an unparalleled opportunity for a youngster to gain real and valuable insights into science.

#### *Annual Science Clubs*

All Israeli universities and research institutions offer afternoon science clubs in the afternoons to students ages 10–18. Some even start at age 7. The programs vary from one institute to another, with the differences related to the nature of the institute. A university can offer subjects in the life sciences, medicine, exact sciences, social sciences, and humanities, while a technical institute focuses on topics such as aerodynamics and computer engineering. A research institute offers courses mainly in its own special fields such as agricultural research, marine biology, environment and so on. Usually learning is stimulated by discussions, films, presentations made by students, and, last but not least, the planning and execution of experiments and reporting of the results.

#### *Summer Science Programs*

Summer courses in universities and museums are similar to those run in science clubs throughout the academic year; the students participate daily, for two weeks, in courses offered by the university. These enables children who do not live in big cities or close to the facility to participate in courses offered by the universities and museums.

Five universities and research institutes in Israel provide on-campus residential programs; these programs enable the participants to get involved in real research laboratories and experience mentorship; they are encouraged to present their extracurricular projects, listen to lectures given by top professors of the hosting institute and engage in social activities. Mentorship programs are offered to 16–17 year old school students; participants in these programs are involved in actual research projects and work in small groups with mentors who are scientists.

#### *Special Residential Summer Programs at the Weizmann Institute*

#### INTERNATIONAL SUMMER SCIENCE INSTITUTE

This program provides some 75 outstanding 12th grade science students from Europe, Asia, the Americas, and Israel with an opportunity to work alongside top Weizmann Institute researchers, as well as to learn something about life in Israel today. Many students selected for this program are chosen when they excel in national science fairs or competitions; their teachers refer others. Upon completing an extensive application form, selected candidates are invited to an interview—after which a committee composed of scientists and professional staff from the Weizmann Institute office interviews the students in their home countries.

The intensive 30 days program is conducted in English and the participants are matched with mentors in groups of 2 or 3, and work in the research labs on current research topics such as: structural differences in normal and tumor cells, applications of lasers and the use of computers in modeling and simulations. Students work with sophisticated scientific instruments including the electron microscope, lasers and computers. The mentors are drawn from among the Institute’s researchers and graduate students. Laboratory work is supplemented with lectures given by senior Institute scientists; each participant can choose a subject in accordance with his or her interests. At the conclusion of three weeks of laboratory work, the students are required to present a seminar and submit a report, and the reports are eventually published as scientific articles in the program’s book. The group then shifts to an altogether different scientific focal point—a field school in the desert located in the southern part of the country. By observing the life

systems, geology, and climatology in the field, students are able to formulate questions that can be explored in the laboratory.

#### SCIENCE, MUSIC AND ART PROGRAM

This special two-week program, run in cooperation with the Society for Excellence through Education, is aimed at sixty 14-year-old students who show potential to excel either in science, music, or art; the purpose of this program is to broaden the scope of youngsters by establishing connections among the disciplines (Maoz, 1990). The Israel Art and Science Academy (which is discussed below) was established several years later, after this experience proved to be successful.

The science, music, and art students go through a selection process that focuses on their ability in their field of interest; the science candidates receive a questionnaire with some problems in science and maths designed to examine their scientific thinking abilities; those who succeed are interviewed at the Weizmann Institute. The most meaningful criteria for the music and art candidates is their creative abilities (composing, improvising, drawing, or sculpting) based on the merits of their portfolio or audition.

In the mornings the participants study in groups based on their interests; in the afternoons they participate in interdisciplinary workshops, working with youngsters drawn from the three domains; evenings are devoted to either lectures by top scientists raising special issues in science, or meeting with professional actors and musicians. The students also have the opportunity for social and sport activities during the lunch break. At the end of the camp, the students organize a farewell party, during which they have a chance to showcase their talents and knowledge gained from the course, including original music performances by the music students, an exhibition of sculptures made by the art students, and demonstration of science concepts. Bringing together three seemingly disparate groups of science, music, and art enthusiasts provides a unique opportunity to enrich and advance students in their own field of interest, and open new horizons in other fields of interest.

#### NATIONAL SUMMER SCIENCE WORKSHOP

This program provides some 30–40 outstanding 11th grade Israeli students with the opportunity to work alongside researchers in a research institute. Senior staff members interview the candidates for this program and decide who will be accepted; they stay at the Weizmann Institute for 13 days, working mainly in small groups of two or three with a mentor in the research laboratories. The evenings are devoted to students presentations, lectures by top scientists, and some social activities. At the end of the program, participants are requested to write a scientific article for the program book.

#### IMPORTANCE OF RESIDENTIAL PROGRAM

Residential programs have special qualities for gifted children: they enable children to meet peers and make friends with other children whom they are not able to meet in any other way. Many gifted children do not socialize easily since they do not find peers who understand them. In some cases they feel like the 'ugly duckling' in their regular environment, while in the camps they find that they are 'swans' in a group composed of similar individuals. On the other hand, many gifted children do not bother to work at school; they acquire knowledge very easily or are not sufficiently challenged. At the residential programs they find out that there are many more students like them and they must make serious efforts if they want to succeed in their fields of interest.

The international program has these qualities as well, but also provides an international flavor and opportunity to meet people like themselves from different cultures. The participants might be the leaders in scientific fields in their own countries in the future. Getting to know potential leaders from other countries may advance understanding among nations, with consequential benefits.

The essence of these programs and the key to their success is 'mentorship'; the student meets his or her mentor in an everyday situation and learns about the mentor's career and way of life through personal example. Historically, mentor-student relationships are the oldest method of educating the gifted and talented (Milgram & Goldring, 1991); research has shown that this approach is very promising (Cox, Daniel & Boston, 1985). This approach is only limited by the difficulty in matching a student with a suitable mentor, as mentors are not easily available. The qualities possessed by the mentor are also crucial: a mentor must be able to anticipate the child's needs in addition to being a high-level professional in his or her field. Similarly, the student should have more qualities than simply being gifted—he or she should be very devoted and persistent; a creative, critical thinker and willing to sacrifice short term satisfactions for the sake of long term accomplishment (Tannenbaum, 1983; Passow, 1991).

#### MATHEMATICS PROJECTS

Tel-Aviv and Bar-Ilan Universities and the Technics accept mathematically gifted high school students into university courses based on passing a special examination; they get university credit for the courses and can even complete university mathematics while still in high school.

Special enrichment program for gifted children in mathematics, Math-by-Mail, is offered by the Weizmann Institute, to gifted children, 3rd–10th grades, all around the country. Mathematicians and mathematics educators prepare the educational materials. The problems, which emphasize the development of

mathematical thinking, are written for each of four grade levels: Level 1 (3rd–4th grades), Level 2 (5th–6th grades), Level 3 (7th–8th grades), and Level 4 (9th–10th grades).

At the beginning of the school year, youth magazines and newspapers advertise the commencement of the year's Maths-by-Mail program with a thought-provoking, though easily solvable problem. Students interested in learning to solve such problems are asked to send in their name, address, and grade level. Those students receive worksheets addressing subject matter and new approaches that differ from that studied at school. For example, problems may deal with graph theory, number theory, statistics, topology, or set theory. Solutions are corrected, graded, and returned to the students with a printed solution and another worksheet. Five such rounds occur during the year. At the end of the year the best students are invited to the Weizmann Institute to participate in a hands-on mathematics experience. They are given a worksheet containing mathematical problems that are clues to a treasure hunt and compete in groups to solve the puzzle.

Experience indicates that all over the country, teachers use these work sheets for enhanced lessons for gifted children and many times an entire family will work together to solve the problems. Some highly gifted students are identified in the Maths-by-Mail program and are subsequently invited to participate in the National Mathematics Olympiad for high school students while still in junior high school. Every few years the material is collected and published; this material is a useful tool for teachers who have gifted children in their regular classes, or those who teach gifted children either in special schools or enrichment programs. It is also interesting to note that the program 'Science-by-Mail' run by the Science Museum of Boston originated from the 'Maths-by-Mail' program in Israel.

## COMPETITIONS AND OLYMPIADS

### Mathematics

The Weizmann Institute of Science runs two nationwide olympiads, one for high school and one for junior high school students. There are no prerequisites for participation in the national Mathematics Olympiad for high school students. Those who apply receive a sample questionnaire used in previous olympiads, which gives them the basis to decide for themselves if they are on an appropriate level to participate. The Mathematics Olympiad for junior high school students is run in two stages: the first questionnaire is distributed to 7th–9th graders at their schools. The questionnaires are checked at the Weizmann Institute and the best students are invited for the second stage held at the Institute; other universities in Israel, such as Tel Aviv University and the Technion hold maths

competitions as well. The best students from all these competitions participate in the International Math Olympiad.

### Physics

The Weizmann Institute also operates a physics tournament, which is a team competition for high school students. The task for the teams, each with five high-school students per group, is to design a lock for a safe using principals of physics. Each team is scored according to three categories: (i) the skill and creativity utilized in the building of the lock mechanism; (ii) the level of comprehension of the other teams' designs; and (iii) the level of success achieved in unlocking the respective teams' safes. In addition, the Technion runs physics Olympiad and Tel Aviv University sponsors a Space Competition. The Ministry of Education supports all of the above projects.

### Israel Art and Science Academy

In 1990 the Society for Excellence through Education established the Israel Art and Science Academy which is a special boarding high school which combines formal and informal education and where the students have the opportunity to meet and work with professionals in art, science, and music. It hosts gifted and able youngsters from all parts of the Israeli society who study science, music, and plastic arts.

The Society for Excellence through Education was founded in 1987 in order to nurture excellence, creativity, and educational leadership among Israeli youngsters gifted in music, art and science. The Society developed and implements a three-year Discovery Program for Junior High School pupils throughout the country. (The name of the program was recently changed to 'Excellence 2000'.) The aim of this program is to nurture excellence among these students, concentrating mainly on developing analytic mathematical thinking, inquiry skills, tools for scientific thinking, broadening of their horizons, and strengthening their self-confidence. The programs are four hours a week for three years. The arts program consists of two hours of sketching and drawing and two hours of photography. The music program deals with composing, improvising, and music appreciation; and the science program works on scientific and mathematical thinking. The children accepted for the programs have to be very good musicians or demonstrate their achievements in drawing. These programs are based on the experience gained in the Science, Music, and Art Summer Program. The Society through Excellence also operates national and international seminars and summer camps for able children in science, music and art, some with the Weizmann Institute of Science as mentioned above.

### THE ADMISSIONS PROCESS

The first screen looks for youngsters who are highly motivated to excel; the second stage involves an interview and participating in a workshop, carried out under boarding conditions. The accepted students have high learning ability and special interest in either science, visual art, or music and they are highly motivated to put a lot of effort in their studies.

### THE EDUCATIONAL PROGRAM

The educational program is unconventional and reflects the conviction that science education must abandon the attitude of narrow specialization. The School believes that an integrative and interdisciplinary approach is essential to deepening students' understanding in the areas that they will choose as their main occupation. For example, science students get expertise in one scientific field, but within this framework they also study the history, philosophy, and sociology of this field and the interrelations of this field with other scientific fields. The students also dedicate 3 hours a week during their time at the school to work in the community.

### Summary

At the end of the millenium Israel has a developed gifted education system within the formal education system. Gifted children are still identified centrally by special identification methods developed many years ago. However, new thinking about identification and provision are broadening conceptions of giftedness. Identification of children with higher potential will be carried out by school teachers who will also guide the programs at the primary schools. At the beginning of Junior High School, the gifted children will be provided with special programs at the universities and research institutions.

Special resources such as universities, research institutions, museums, and other professional organizations are still neglected resources in educating gifted and talented children. These bodies have the knowledge, the personnel, and the equipment that can cater to highly intelligent students and give them insight into exciting and challenging areas and methods of study. These settings can also provide gifted individuals with mentors. Globally, there appears to be only sporadic efforts to use these resources. Israel provides a good example of a national network of extracurricular science education in all its universities and some research centers, but still more can be done in science, music, and the arts.

Science, natural history, and art museums are now active in the field of education, while music institutions are less so. A promising sector is science-based industry with research and development departments. These industries can also adopt youngsters into their

research and development departments and enable them to work with their professionals; implementing such programs in most universities and other institutions is neither complicated nor expensive. The most important factor—the personnel—is already in place, together with the necessary knowledge and equipment. However, commitment is needed to implement unique education programs, shaped by the mission of the individual institute.

### Conclusion

There are increasing number of research papers in many Arabic countries in the Middle East, focusing on both the conception of giftedness and the conception of creativity and education of the gifted and talented. In addition, teacher training programmes, professional development courses and research projects are carried out at some Arabic universities concerning developmental, motivational, social, emotional, and cognitive aspects of gifted children and adolescents. Since 1980, the number of gifted and talented children in special provisions or programs has increased significantly, however teacher education is not keeping pace. In Israel, considerable emphasis has been placed on gifted and talented children, and extensive resources are allocated to their identification and the development of programs and special provisions to meet their special needs. If we are truly concerned about optimizing the region's educational systems and processes, then we must continue to develop special provisions to meet the needs of gifted children, nurturing the national resources that our gifted and talented students represent.

# Psychological Research on and Education of Gifted and Talented Children in China

Jiannong Shi<sup>1</sup> and Zixiu Zha<sup>2</sup>

## Introduction

In ancient China, there was a folk custom called 'shier' (child prediction). According to this custom, when a child was one year old, he or she would be tested by exposing stationery objects, such as writing brushes and paper, sewing items, such as threads and needles, foods and cosmetics before him/her. People thought that the first object the child tried to grasp could tell whether he or she would be avaricious or disinterested, intelligent or not (Yang, 1994). The official selection and education of gifted and talented children, called 'child prodigies', dates back to the 18th century. An examination system for selecting gifted children known as 'Tong Zi Ke' (the Child Examination) existed in the feudal dynasties since the Western Han Dynasty (206 BC.). But a relatively strict and formal law procedure for selecting gifted and talented children was established in the Tang Dynasty. The law of the Tang Dynasty prescribed that a child under 10 years old who was able to read and understand either 'shijing' (the Book of Songs) or 'lunyu' (the Analects of Confucius) and say over ten articles would be instated as placeman, while one who was able to read and understand the Book of Songs or the Analects of Confucius and say over seven articles would be dubbed a certificate. The policy of the Child Examination lasted until the end of the Qing Dynasty.

However, it is only since 1978 that widespread, systematic and scientific research on and education of gifted children has been undertaken in the mainland of China. The year 1978 marked an abrupt turn in Chinese history. The country energetically encouraged modernization in the areas of agriculture, industry, defense and science and technology. Since then, large numbers of talented scientists, engineers and other experts have been urgently needed. In response to this need, a Cooperative Research Group of Supernormal Children

of China (CRGSCC) was set up across the country under the leadership of Professor Zha et al. and a special class for intellectually gifted adolescents was set up in the University of Science and Technology of China (USTC) in 1978. These were two milestones in the history of research on and education of gifted and talented children in China since 1949 (Shi & Xu, 1999). Since then, a new research project on identifying, studying and educating gifted children has been undertaken (Zha, 1985, 1993).

The purposes of the research are: (1) to identify and distinguish extraordinary children who are gifted intellectually and to educate them in order to promote and accelerate the proper development of their potential; (2) to explore the factors which accelerate the development of intelligence in such children and to analyze the process of formation in order to improve the education of all children and thus raise the level of mental development of future generations; and (3) on the basis of the above results, to accumulate material for exploring theoretical problems concerning children's development, such as the relationship between intelligence and personality, the function of nature and nurture in the growth of children and so on.

Under the leadership and influence of the CRGSCC much has already been achieved, and hundreds of gifted children and adolescents have been identified, investigated and followed up; a series of comparative studies on mental abilities and personality traits between gifted and normal children have been carried out; a battery of cognitive ability tests and personality trait questionnaires have been compiled; and various kinds of gifted education programs have been established and developed rapidly.

In Hong Kong, the gifted education movement started relatively later. Even though a non-profit organization devoted to the provision of gifted education in Hong Kong named Gifted Education Council (GEC) was formed in 1988, the governmental policies of the provision for gifted education or a strange structure were not included in the Education Commission Report until 1990 (Wu & Cho, 1993; Tsui, 1995).

<sup>1</sup> Institute of Psychology, Chinese Academy of Sciences, Beijing, China. E-mail: jnshi@public.east.cn.ne

<sup>2</sup> Institute of Psychology, Chinese Academy of Sciences, Beijing, China.

Since then, several enrichment programs for the gifted have been created and researchers from the Gifted Education Council, the Hong Kong Institute of Education, the University of Hong Kong, and the Hong Kong Polytechnic University have been involved in several psychological and educational projects that study gifted and talented children. In addition, the G. T. School (School for gifted and talented children) was established in 1996 under the control of the Gifted Education Council.

**Conception and Identification**

*Conception*

The term ‘supernormal children’ was created and employed by psychologists in mainland China since 1978 when the CRGSCC was set up. There are two reasons for Chinese psychologists to create the term of supernormal children: (1) ‘gifted’ in Chinese ‘tian cai’ means the God’s bestowal upon man; and Chinese psychologists do not think that high ability is totally inborn. (2) ‘Supernormal’ means some children are relatively superior to most normal children. Hence, ‘supernormal’ is a term with statistical meaning (Liu, 1983). In general, the performances of an unselected age group follow the rule of normal distribution and can be mathematically expressed as

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where,  $x$  represents the real performance of an individual;  $\mu$  represents the expected performance or mean performance of the whole; and  $\sigma$  represents the standard deviation. If  $x \geq \mu + 2\sigma$ , then the individual can be treated as a supernormal child (Shi & Xu, 1998).

In Hong Kong the definition of giftedness in Marland’s (1971) report to the United States Congress was employed. According to Marland’s definition of giftedness, an individual with the following features will be identified as the gifted. These features are: (1) high IQ or high level of conventional intelligence; (2) special academic aptitude; (3) creative thinking; (4) superior talents in the visual and performance arts; (5) high leadership ability; (6) psychomotor ability (Zha, 1993, p. 8; Tsui, 1995, p. 35). But an increasing number of psychologists and educators are influenced by Gardner’s theory of multiple intelligences. Then, the definition of giftedness must be defined in a broader sense.

*Identification*

How can gifted and talented children be identified? What are the criteria and methods to be used? These problems are closely related to the concept of giftedness. In our opinion, gifted children are not only highly developed in intelligence or ability but also possess greater creative potential and other positive personality

traits. All of these factors interact with each other to form the mental structure of the gifted. On the basis of this view of giftedness, the principles and procedures for identifying the gifted were explored and formed progressively (Zha, 1983, 1986a, 1990b; Shi & Xu, 1997).

Principles for Identifying the Gifted

In light of foreign experience (Roedell et al., 1980; Khatena, 1982; Tannenbaum, 1983; Freeman, 1985) and on the basis of our own practice and exploration in identifying the gifted, the following principles for identifying gifted children have been formulated (Zha, 1986, 1993):

- (1) Identification in a dynamic comparative investigation. Since the intelligence of gifted children is developing rather than fixed, and because that development is influenced by cultural, environmental and educational factors, identification of the gifted ought to be carried out in a dynamic comparison with normal children of the same age under similar societal conditions.
- (2) Identification with multi-criteria and multi-methods. Since the manifestations of giftedness are different, multiple criteria and different methods should be employed.
- (3) Investigation of personality traits as well as intelligence. Excellent achievement depends not only on superior intelligence but also on certain personality traits. Moreover, the intelligence potential itself is influenced by the personality traits, as a result, both intelligence and non-intelligence factors are equally important for the identification of gifted children.
- (4) Quantitative and qualitative responses recorded and analyzed. In viewing the development of intelligence as a dialectic unity of quantitative and qualitative changes, children should be identified on the basis of the results, speed of their responses, and the processes, forms and strategies of the responses.
- (5) Identification with special education. Identification as a means to serve the education of gifted children and education can not only raise the level of giftedness but also serves to continue the identification in a practical setting. Giftedness is shaped by the environment and education to which the children have been exposed. Therefore it is necessary to continue monitoring the gifted during the educational process as a continuation of the identification process.

Criteria and Methods for Identifying the Gifted

On the basis of the above-mentioned principles, the following criteria and methods for identifying the gifted showed in Table 1 were adopted (Zha, 1993).

### The Identification Procedure

In general, both individual identification and collective identification or mass screening have been used to select the gifted and talented children in the past twenty years. The individual identification was mostly used in the initial stage of the research of CRGSCC though it is still used now. There are four steps for identifying a gifted individual: (1) A child is nominated by his/her parents or teachers or reported in newspapers, or on television and broadcast; (2) the child is sent to institutions and introduced to the professional researchers; (3) the child is tested with the standardized intelligence test or cognitive ability test and the parents of the child are asked to obtain the information about some personality traits of the child; (4) the child is continually observed and identified dynamically. The individual identification seems efficient but not sufficient as it is too time-consuming.

For the collective identification or mass screening mainly the following steps are followed (Zhou & Zha, 1986; Zha, 1993; Shi & Xu, 1998):

Step 1, Application. Individuals who want to be enrolled in a special class for gifted children, are asked

to fill in the application forms and to present information about their developmental history, facts of gifted expression, family education, family background etc.. In the case of young children, their parents or recommenders are asked to fill in the application forms.

Step 2, Primary screening test. The general or conventional intelligence of the children is measured with intelligence tests such as Stanford-Binet Intelligence Test (revised) and the Wechsler Preschool and Primary Scale of Intelligence (revised). In addition, the knowledge and ability of children concerning the major subjects are measured by experts.

Step 3, Retest. The children who pass the primary tests will be tested with 'Test for Identifying the Cognitive Ability of Supernormal Children (TICASC)' developed by the CRGSCC. The child who can meet one of the following three criteria will be expected to enter the special class for the gifted. The three criteria are: (a) a score which is two or more standard deviations above the mean score of the same aged children; (b) a score which is above the mean score of the children two years older; and (c) a score which is over the 95th percentile of the same aged children. For the children with special talents, their school works such as composition, painting, machine models, etc., should be appraised by experts.

Step 4, Further confirmation. To gather more information about the personality traits and physical conditions of the children who are expected to enter the special class, the children need to take some physical tests, and their parents or former teachers need to be interviewed or complete some questionnaires.

Step 5, Identifying through practice. In order to determine whether a child who is identified as gifted should stay in the regular classroom or should participate in a special program, the child will be placed in a special class for several weeks. Here, further identification through practice (student's learning process) is emphasized. The major practical activity of children is learning, i.e. being educated. Hence, to educate them in equal conditions and environment and investigate their potential and actual performance levels is a continuation of the identification procedure.

In the mainland of China, the instruments and methods that could be used in the identification of the gifted are far from satisfactory. Our research implied that as there are different kinds of gifted children, they also differ from normal children in different ways. Therefore, various criteria should be determined for the design of effective tests and appropriate methods for identifying different kinds of gifted children. This problem involves not only the need for better instruments but also requires a better comprehension of the concept of giftedness. Consequently, the solution of the improved instrument problem should be based on theoretical research.

Table 1. Criteria and Methods of the Study and Identification.

	Dynamic comparative research	
	Criteria	Methods
Cognition	thinking observation memory	cognitive experiment intellectual test
Creativity	creative thinking creative imagination ability to solve problems creatively	creative thinking test analysis of the process of creative activities etc.
Learning ability	speed style of mastery depth of knowledge firmness	test concerning learning ability and achievement, observation and analysis of learning process
Special talent	math foreign language leadership drawing, calligraphy music	test concerning special talent, assessment and observation of product (or home work)
Personality traits	interest, motivation intellectual curiosity confidence persistence independence	questionnaire observation, educational experiment, interview

In Hong Kong, a battery of tests in addition to self/peer nominations was used in identifying and selecting gifted students for the limited gifted programs in the initial stage (Wu & Cho, 1993). Recently, with the impact of the Gardner's multiple intelligences theory, different aspects of children's intelligence were considered. A set of multiple intelligences tests was developed by the Gifted Education Council and used to identify gifted children (Li & Chan, 1996).

## Psychological Research

### *Development of cognition*

#### The Memory and Metamemory of Gifted Children

According to common findings of the previous studies, the ability of excellent memorization is one of the obvious characteristics of intellectually gifted children (Huang, 1990; Zha, 1993). However, finding the phenomena is one thing, knowing its cause is another one. In order to detect why gifted children have, in general, stronger memory ability than normal children, the abilities of memory monitoring and memory organization of gifted children were tested and the relationship between memory performance and metamemory of gifted and normal children was analyzed (Shi, 1990a, 1990b). The results show that (1) gifted children were superior to normal children not only in the amount of recall, but also in the speed of remembering and in some aspects of metamemory, such as memory monitoring and memory organization; (2) there were close relationships between the memory performance and the organization of memory, especially between the speed of remembering and memory organization; (3) the relationship between memory performance and memory monitoring was complicated, but the speed of remembering, as one important aspect of memory performance, significantly correlated with memory monitoring; (4) there was a close correlation between the two components of metamemory, memory monitoring and the organization of memory. The results of these studies indicated that it was better to use both, the amount of recall and the speed of remembering, as an index of memory performance.

#### Thinking and Reasoning Ability of Gifted Children

In the last twenty years, Chinese researchers have found that the ability of analogy or analogical reasoning is one of the main aspects where there are significant differences between gifted and normal children. A set of analogical reasoning tests, including geometrical or figural analogy, numerical analogy, and verbal or semantic analogy was developed (Zha, 1984). With this set of analogical reasoning tests, the researchers can not only record the scores of the performance, but also analyze the level of analogical reasoning of the children. Zha and her colleagues found that gifted children were not only able to get higher scores than

normal children, but have a higher level of analogical reasoning as well (Zha, 1984, 1990; Wang, 1990).

#### The Development of Creativity in Gifted Children

Because many psychologists have suggested that creativity is one of the most important manifestations of giftedness, the creative thinking of gifted children is the main aspect that Chinese researchers and educators have focused on. A creativity test was developed and included, as a sub-test, in the Cognitive Ability Test for Identifying Supernormal Children (CATISC) (Zha, 1986c). Several comparative studies have been conducted on creative thinking between intellectually gifted and normal children in the last twenty years. Furthermore, psychologists from the Institute of Psychology, Chinese Academy of Sciences, joined the collaborative cross-cultural study on technical creativity of gifted and normal children between China and Germany. This study was supported by the Volkswagen Foundation (Hany, 1994; Shi et al., 1995, 1998; Hany & Heller, 1996; Heller & Hany, 1997). The results show that: (1) the mixture of longitudinal and cross-sectional design is very practical and efficient for the study on technical creativity of children from two countries with different cultural backgrounds; (2) two countries as two variables of culture have impact on the development of technical creativity in children; (3) intelligence is one of the factors which plays the most important role in the development of children's creativity; (4) children's performance on technical creative thinking tests increase as they grow up.

Recently, the development of creative thinking in children has received much attention from psychologists and educators due to the need for rapid economic growth and to the educational reform in China. The relationships between creativity and intelligence and personality traits are currently under investigation. In addition, a theoretical model about creativity, called System Model of Creativity, has been proposed (Shi, 1995; Shi & Xu, 1997a, 1997b, 1997c, 1999). It is suggested that, in this model, the intelligence current rather than one's intelligent level itself plays an important role in creativity (Shi & Xu, 1999). The intelligence current is controlled by one's attitude about a task, personality traits, and environmental factors, etc.

#### *Development of Personality Traits*

As Chinese psychologists and educators recognized the importance of personality traits in the development of gifted children at the very beginning of the research on giftedness, research on the developmental changes of personality traits of gifted and normal children is among of the most important issues on which the CRGSCC has been working. Some personality questionnaires have been compiled by the CRGSCC. The questionnaire for adolescents named Chinese Adolescents Non-intellectual Personality Inventory (CA-NPI)

was widely used in the mainland of China after it was compiled. The researchers of the CRGSCC used CA-NPI to investigate the ambition, independence, emulousness, perseverance, curiosity, and self-awareness (Yuan & Hong, 1990; Hong, 1998). In 1994, some researchers of the CRGSCC started a collaborative cross-cultural study on self-concept of gifted and non-gifted children with researchers from the University of Nijmegen, Netherlands (Peters et al., 1995; Chen et al., 1997; Kong & Ye, 1998). It was found that the gifted children were superior to the normal children not only in many aspects of cognitive abilities, such as memory, reasoning, spatial ability, and so on, but in some personality traits, such as ambition, independence, and curiosity etc.

### Education

In China, attention has long been given to talented children in the arts, for example, music, painting and dance. Special schools or classes have been established to nurture these talents. However, special education for intellectually gifted children did not receive much attention prior to 1978. The establishment of special classes for gifted adolescents or youth at the University of Science and Technology of China (USTC) in 1978 marked the beginning of experimental educational procedures for gifted children in the mainland of China (Xin & Chen, 1986; Zhu, 1987).

#### *Kinds of Gifted Education*

During the past twenty years, four kinds of special education programs have been in existence for gifted children and adolescents, which are summarized in Table 2.

#### *Characteristics of the Gifted Experimental Class*

The gifted experimental class differs from normal classes in the following ways (Tao, 1987; Di, 1990; Zha, 1990a; Zha, 1993):

- (1) The establishment of the gifted experimental class is based on the children's intelligence or special talent, while the normal class is based on age and cultural knowledge.
- (2) The period of schooling has been shortened for the gifted experimental class. In both, primary and high schools, the period is four or five years for the gifted, while in normal schools the period is six years.
- (3) In addition to the moral, intellectual, and physical development provided in the normal classes, gifted children are encouraged to develop analytic skills, to solve problems creatively, and to develop good personality traits.
- (4) There are alternative courses to meet the special interests and needs of gifted children in the experimental classes that are intended to further develop their potential and abilities.
- (5) Teaching materials are modified according to the cognitive levels and traits of the gifted children to promote the development of their creative ability and reasoning skills.
- (6) The instructional strategy attempts to make full use of and promote students' ability to study independently. Heuristics, discussion and research methods are adopted instead of cramming.
- (7) Attention is focused on the development of students' self-concept and self-evaluation. In

Table 2. *Kinds of Gifted Education.*

Kind	Description
Enrolled earlier or skip	The gifted children who have passed certain examination are allowed to enter primary/high school or university earlier than the normal, or jump into higher class.
Special class	Gifted experimental classes have been held in more than 50 primary/high schools overall the country; besides, several universities have set up special classes for gifted adolescents.
Special schools	All students of this kind of school are enrolled as gifted children. The educational programs of the school are only for the gifted, for example, the Hong Kong G. T. School.
Special activity within/without the campus	Special courses for computer and the Olympic school of mathematics (physics/chemistry) have been held in certain districts overall the country; children's palace has been set up to organize various science/arts courses; activities concerning scientific research, invention, and arts have been undertaken in school.
Vacational or weekend programs	Many leisure time schools have been setup to devote special courses, such as visual and performing arts, mathematics and sciences, social activities, and so on for the special need of talented children.
Instructed individually	The gifted, who are studying in the normal class, are instructed individually by the teachers/parents to learn in advance or undertake research work in leisure time.

addition, the students are supported in setting up high ideals and developing abilities of self-regulation, self-education and self-actualization.

- (8) A proper balance is maintained in the relationship between collective education and personality development. Students arrange part of their study time at school on their own, in order to develop their own interests and abilities.
- (9) The assessment of the results of the educational program depends not only on academic performance (e.g. test results, proportion of students entering a higher grade in school, etc.) but also on appropriate criteria and methods that assess the all-around development of the gifted.

#### *Effects of the Educational Programs*

Remarkable progress in gifted education has been achieved in China since 1978. The main results are as follows:

Gifted children and adolescents completed their studies in a shorter period and with excellent results.

Gifted children, who studied in primary or middle school, graduated earlier than the same aged normal children with excellent results through either gifted classes or by skipping grades in normal schools. For example, in Beijing No. 8 Middle School, students of the first gifted class finished the fifth and sixth grade curricula of primary school along with all the of high school curricula within four years, which is four years less than the normal period. They passed the unified university entrance examination with a total score of 35.9 points higher than the normal class of that school. Subsequently, 27 students (average age 14) out of 29 have been enrolled by key universities (Gong, 1990).

The gifted adolescents, averaging less than 15 years of age, have been enrolled in either gifted youth classes or normal undergraduate classes at universities since 1978. Results here have also been excellent. For example, by 1998 the USTC had held twenty one gifted youth classes, with a total registration of more than 800 students. More than 500 students graduated from USTC between 1983 and 1998, and 73.7% had been enrolled in domestic/overseas graduate schools. Among them, more than two hundred students obtained Ph. D. degrees (Ye & Kong, 1998).

Overall, gifted education has been beneficial in developing the potential of gifted children and adolescents. Gifted children and adolescents, who show extraordinary progress in learning, make further gains in intelligence through gifted education. For example, research was done on the students of the first class of the Beijing No. 8 Middle School shortly before graduation using seven tests, including creative thinking and analogical reasoning. The results were compared with both, same aged normal students and older students of the same grade. The comparison showed that the gifted scored notably higher than the same aged normal children on each test and scored

higher on five tests than the same grade normal children, who were three to five years older.

A battery of creative thinking tests have been used to examine a sample of gifted students of the third year gifted youth class of USTC and the normal students of the same age (the sample was taken from a population of freshmen and middle school students). The results showed that the mean scores of the students from the gifted youth class are markedly higher than the mean scores of the normal students (Kang, 1985).

Gifted children and adolescents were in good health, physical examinations were carried out for the gifted children and adolescents. In general, the average values of height, weight and chest measurement of the gifted reached or exceeded those of the same-aged normal children in China. For example, the USTC investigated the students from the gifted youth class by physique criteria issued by the State Education Commission. Results showed that most of the students of the gifted youth class exceeded the criteria. This suggests that to enter school earlier or to shorten the period of schooling is not related in a negative way with the health of the gifted (Xin, 1986).

The meaning of the above results can be summarized as follows:

- (1) The gifted children possess tremendous potential and the potential could be thoroughly developed through gifted education in accordance with their levels and characteristics.
- (2) The gifted education experiments of primary and high school have been established and coordinated with gifted youth classes of universities. Although the gifted education system is still in an embryonic form, it fills in gaps in the regular education system of China.
- (3) The gifted experimental classes and youth classes in China provide an experimental base for systematic research on the mental development of gifted children.

#### **Issues**

Fruitful results have been obtained in the field of research on and education of supernormal children in China during the last twenty years. However, several essential issues or problems still exist. In summary, the issues or problems are: (a) a severe shortage of financial support and research staff for the study of gifted children; (b) a lack of instruments to study gifted and talented children; (c) a lack of programs for training the teachers of the gifted programs; and (d) a lack of well-designed studies on the development of visual and performing arts and athletics in talented children, especially from the perspectives of psychology and education.

In the future, research efforts in China should be focused on the following topics: (a) implicit learning and creativity; (b) brain function and giftedness; (c)

leisure time activities of eminent individuals; (d) personality traits and situational problem solving, etc.

### Acknowledgements

The authors would like to express their thanks to Natural Science Foundation of China ( Grant No. 3870237 and No. 39700045) and Chinese Academy of Sciences, as well as to Miss Kimblerly from University of Michigan and Prof. Leticia Hernández, University of Munich, who spent much time to correct the English of our manuscript.

# Programs and Practices for Identifying and Nurturing Giftedness and Talent in Asia (outside the Mainland of China)

Wu-Tien Wu<sup>1</sup>, Seokhee Cho<sup>2</sup> and Utami Munandar<sup>3</sup>

## Introduction

In terms of human history, the development of *Gifted and Talented Education* (GATE) has been experiencing the following changes in the Asian region: from emphasizing equality to searching for equity and excellence, from educating the elite to developing talent for all, from incidental and fragmental enrichment to systematic and holistic education (Wu, 1998). The current hot topics are: multiple intelligences, cultural diversity, the gifted handicapped, ecological planning, differential programs, and the role of gifted education in educational reform. At the very cross point of the old and new centuries, much attention has been paid to the transition of gifted education. However, each country in Asia differs in the actual practice of providing special education programs for gifted and talented students. A few countries started implementing GATE programs in the 1960s and are now practicing it on a large scale at the national level. Most countries became aware of the need to provide the gifted and talented with special education programs on an experimental basis and/or at a private level only in the 1980s. In the 1990s, a variety of programs were designed according to the worldwide movement of educational reform in many Asian countries.

In this chapter, the current status of GATE in some Asian region countries, namely, India, Indonesia, Japan, Korea, Philippines, Singapore, Taiwan, and Thailand, will be reviewed with respects to policies, identification, programs, and issues for educating the gifted and talented.

## India

India's philosophy and policy of education are reflected by the statement of the Ministry of Education that education can be the most effective means for equalizing opportunities and reducing disparities between human beings. In a democratic society, it is considered a fundamental right of citizens. In the ultimate analysis, therefore, the aim must be to enlarge the coverage and improve the quality of education so that a person belonging to any region, caste, creed, sex or economic strata, would have the chance of developing his or her potentials to the full (Maitra, 1997). In India, equity, quality and relevance are the three most important facets in planning the development of the educational system (Maitra, 1997). Since its independence India has made considerable progress in quantity and quality of all types of educational institutions and programs. Education is the second highest sector of budgeted expenditure after defense (a little more than 5% of the country's GNP), gradually becoming balanced in favor of rural areas, which get almost 40%. Three major expert bodies at the national level play crucial roles in educational planning: the National Council of Educational Research and Training, the National Institute of Educational Planning and Administration, and the University Grant Commission. These bodies are responsible for major policy decisions about academic excellence, financing scholarships, higher education abroad, exchange programs, national curriculum, organization of special schools, and selection criteria for teachers, scholars, and eminent persons. Concerning gifted education and development, India believes in the development of giftedness rather than calling a few individuals gifted. The overall educational objectives include all types of GATE. There are no rigid criteria of giftedness; rather, one finds frequent use of the concept 'talent' in official documents. The focus is more on universalization of primary education with an aim of full literacy in India (Maitra, 1997).

### Identification

It is estimated that if we restrict the number of gifted and talented children in India to 3%, there will be about 25 million of them. It may vary from 5 to 10% of the population, if we include not only general intellectual and academic abilities but also leadership qualities, talents in visual and performing arts as well as in the emotional domain. To nurture talent particularly among the disadvantaged in society, the government of India, in pursuance of National Policy of Education (1986), launched the *Navodaya Vidyalaya Scheme* (N.V.). Under these schemes, 378 N.V. (residential institutions) have been established throughout the country, with the objective to make quality education accessible to talented children. At least 75% of the seats in a district are for candidates from rural areas. There are provisions for reservations for girls, as well as for disadvantaged students. The screening instruments consist of mental ability tests (60%), arithmetic (20%) and language (20%). The mental ability tests are non-verbal and culture-fair. To identify brilliant students the *National Council of Educational Research and Training* (NCERT) awards 750 scholarships each year including 70 scholarships for socio-economically disadvantaged secondary school students. The selection procedure consists of a two-tier selection through state and national level examination. Also run by the government are the Navyug schools providing quality education to highly able students from low to middle socio-economic strata. Selections are conducted by NCERT for junior section and by SCERT for senior sections. There is however no provision for nursery or pre-school children (Maitra, 1997).

Educational institutions like Jnana Prabodhini (which means 'Awakener of knowledge') started in 1962 with coaching in academics for those gifted in abstract reasoning, using Guilford's SOI model as a stepping stone; now also identify those gifted in creativity and interpersonal behavior for formal educational programs; whereas the non-formal programs identify those who are 'responsible, responsive and cooperative'. These non-formal programs are open to all, especially the under-privileged (Bapat, 1998).

### Programs

In India the private sector plays an important role in providing programs for gifted and talented students. The high interest in providing programs for the gifted and talented can be seen from many papers presented by various educational institutions in India at the 5th Asia-Pacific Conference on Giftedness, September 1998.

The Jnana Prabodhini Prashala in Pune is one of the schools for gifted students. It has a program to discover whether a gifted student when motivated and properly guided, can achieve excellence by learning various skills (Bhalerao, 1998). The syllabus is flexible and imparted by the teacher during the regular school

hours. This program is implemented in the fifth standard. Gifted secondary school students from Jnana Prabodhini, Yuvati Vibhag, are involved in a program consisting of group tasks to develop attitudes for cooperative working (Patange, 1998). For teachers of the gifted Jnana Prabodhini provides teacher education programs (Mehta, 1998).

Enrichment programs for the gifted are provided by the Mensa (inception 1975 in Pune), an international non-profit organization where the only criterion for membership is a high IQ score. Its aims are: identification and nurturance of intelligence, providing a stimulating and enriched environment for high IQ people, and conducting research in psychology and other social sciences (Damle, 1998).

### Problems and Perspectives

As stated by Bapat (1998), ideally all schools should cater programs for the gifted, and various establishments in the community should act as places of exposure and learning, yet it is recognized that this is not yet accepted practice in India and programs for the gifted are few in number. The existing programs are mostly for secondary school students. Some mainstream schools have an important role in catering the needs of the gifted, but most are still in its experimental phase (Bhagwat, 1998). Therefore, to cater to the education of the gifted and talented more teacher educational programs are needed. To date there is no clearly formulated policy for education of the gifted in India. Rather, India believes in "quality education for all," with special attention for the underprivileged and socio-economically disadvantaged people. The perspective of education for the gifted in India has to be seen in this light. However, several institutions and organizations, primarily from the private sector, have established various activities and programs for the benefit of the gifted and talented.

The following intriguing questions posed by Bhagwat (1998) may reflect perspectives of gifted education in India: "It is high time that our system (in India) should think on certain basic questions like 'do the gifted children need a gifted curriculum?', 'is it possible to have special schools with special curriculum?', 'does the economy of the nation have the provision for it?', 'what can be the compromise for developing the programs for gifted children?', 'can mainstream school provide the enrichment opportunities for the gifted ones'?"

### Indonesia

In Indonesia's Broad Outline of the State's Policy 1998 (GBHN, 1998) with reference to Education (page 175, paragraph b) it is articulated that "students with extraordinary high intelligence are entitled to special attention and services in order to optimize the development of their achievements and talents/gifts . . ."

This is in line with the 1989 Second Law on the National Education System which states explicitly that "citizens with extraordinary abilities and intelligence are entitled to special attention" (Chapter III, paragraph 8/2). More specifically "each student at levels of education has the right to get educational treatment (opportunities) in accordance with his/her giftedness/talents, interests and abilities, and to complete an educational program earlier than the regular time," meaning that according to educational policy both enrichment and acceleration are possible.

### *Identification*

With a population of more than 200 million in 1998 and composed of a large number of ethnic groups distributed over about 3000 islands, it is a real challenge for Indonesia to identify its gifted and talented children and youth (Marat, 1992). There is a shortage of experts and testing instruments for the identification of gifted children at a national level (Munandar, 1992, 1996).

When the Ministry of Education and Culture began providing grants to high achieving but economically disadvantaged students of elementary, junior, and senior high schools, the identification was primarily based on achievement tests and when possible on psychological tests (intelligence, aptitude). Since 1982, with the start of the project on education of the gifted by the Ministry of Education and Culture, identification involves intelligence, creativity, and standardized achievement tests, conducted by psychologists and teachers. Simple screening tests were constructed and used by school teachers, items of which include learning behavior (intelligence), creativity and achievement motivation (Munandar, 1996).

In 1990 tests were constructed to identify the underachieving gifted and in 1993 teacher-, peer-, and self-nomination scales (Munandar, 1996). The need for using creativity tests, in addition to intelligence and achievement tests, to identify the gifted has been increasingly recognized and implemented both by state as well as private institutions and practitioners.

### *Programs*

In 1982 a pilot project on educational programs for gifted students was launched by the Ministry of Education and Culture with the establishment of project schools in urban (Jakarta) and rural (Cianjur) areas. This project consisted of enrichment modules for junior and senior high gifted students. A 7-Year Plan of educational provisions for the gifted was formulated with long-term goals for 1982–1989 and an Action Plan for 1982–1983. The project lasted only until 1986, but its main concepts are still used and implemented in the development of a Plus Curriculum since 1994 by the Center for Curriculum Development, Ministry of Education and Culture. This Plus Curriculum has been field-tested in several locations in Java and Sumatra,

and is still in the process of development, evaluation, and improvement.

To increase the quality of education throughout the country another policy in the 1990s of the Ministry of Education and Culture has been to promote the establishment of 'High Schools of Excellence' (Sekolah Unggulan) for students with high ability and intelligence in each of the 27 provinces. To date there are 105 schools of this kind, one with an intake of students at a national level (scope), 25 at a provincial level, and 79 at a local level. Some are special schools, others have special classes. The status of these schools are state institutions (64), private (25), collaboration between state and private (14), and collaboration between private institutions, organizations, or foundations (2). One has been existing for more than 15 years, but most of them were established only recently. Therefore, the developmental stage of these High Schools of Excellence varies.

Other existing programs for optimizing high ability and achievement are (Marat, 1992; Munandar, 1998):

- Scholarships for overseas study in science and technology.
- Science contests: schools are urged to form Youth Science groups and contests for innovative-productive performance are held yearly.
- The *University Research for Graduate Education Project* (URGE), competitive grant and fellowship programs: the Graduate Team Research Grant, and the Young Academics Program (for recently achieved PhD and Doctorate).
- Programs for gifted and creative preschool children, established by private organizations/foundations (e.g. the Creativity Development Studio, etc.).

### *Problems and Perspectives*

After nearly two decades of educational programming for the gifted, several inhibiting factors still exist, such as the shortage of expertise and assessment instruments, the lack of trained teachers for the gifted, the scarcity of professionals who are familiar with issues of giftedness, and the want for educational facilities and equipment for implementing enrichment and acceleration programs.

However, there are also contributing factors to mention, e.g. more and more studies are being conducted on giftedness and gifted education, and the participation in and collaboration with regional and international bodies/organizations on G/T (WCGTC, APF-WCGTC, ECHA, etc.) are increasing.

A recent national survey regarding policies in gifted education showed that experts, governmental and school administrators, teachers, and parents are in favor of education for the gifted, and that it should be granted the same priority as education for regular and handicapped students (Munandar, 1998). This indicates a positive public attitude toward GATE.

The monetary and economic crises in Indonesia since mid 1997 will have an impact on the education sector, in terms of the decrease of student enrolment rate, an increase of student dropout rate, and that presumably less funds will be available for educational provisions for the gifted and talented. However, with the backing of state's policy as mentioned above and the support of the society and the private sector, there is still a promising future for GATE in Indonesia.

### Japan

After World War II, Japanese education was extensively reformed. Its school system was changed from a 'dual system' into a 'ladder system'. As a result, gifted education has become an almost taboo subject within Japanese society (Chiba, 1980; Hirano, 1992). However, the Japanese government has recently discovered that the Japanese school system fails at developing students' creativity. In an effort to find educational alternatives, Japan hosted an international workshop on 'Education of the gifted in science and technology' in collaboration with UNESCO (NIER, 1993). Afterwards, the Central Council for Education, an advisory body to the Japanese Ministry of Education, introduced proposals aimed at providing differentiated academic programs, which would reflect students' individual differences in abilities. Other exceptional steps would be taken to nurture the special abilities of the gifted.

### Programs

#### After-School Activities

Special opportunities presently exist for public school students who wish to enrich their education through after-school clubs and classes. These extracurricular activities are open to all students and a high percentage choose to participate. While these activities are not offered especially for gifted and talented students, they provide students with a much broader scope of activities than those contained in the regular curriculum.

The Research Institute of Education for Brilliant Children, established as a private organization in 1965, has opened classrooms to intellectually gifted young children. As the scope of intelligence education within Japan has broadened since 1972, important achievements have been continuously made (Chiba, 1980).

#### High School

High schools are ranked according to their ability to prepare students for the university entrance examination. In contrast, a more egalitarian system is used for ranking elementary and junior high schools. High schools, especially in urban areas, are ranked according to four levels and based upon the number of students who enter the top universities (Stevenson et al., 1992).

Students are admitted to high school, at a given level and school, on the basis of the national entrance examination results. Competition for entrance into the

top high schools is keen because they provide better preparation for passing the university examination. It is primarily through entrance examinations, first for high school and later for university, that individual differences in ability among students become acknowledged (Stevenson et al., 1992). However, despite these differences, schools do not provide students with gifted educational programs, in a strict sense, since all students are taught according to the same curriculum even though there are some efforts to cater students' individual differences in regular schools and regular classes.

#### Early Admission to College

Educational reform for the gifted began with the college level. In accordance with the report made by the *Central Council for Education* (CCE), the Japanese government revised the School Education Acts, as they apply to the college admissions (Japan Ministry of Education, 1997). Henceforth, an exceptional few who display giftedness in maths and physics will be allowed to enter college even before the age of 18. The reasons for restricting the academic areas of giftedness were: (1) it is easier to identify the scientifically and mathematically gifted even among youngsters; (2) giftedness in maths and physics has to be nurtured in a school setting; (3) it has been proven that acceleration is an appropriate approach for nurturing giftedness in physics and maths (Japan Central Council for Education, 1997).

The universities themselves will decide whether or not to accept the accelerated students. However, those colleges that do accept the accelerated students should have doctoral program. They should also provide academic and career guidance, and provide alternatives when these students want to change their academic fields.

In contrast, the CCE report suggested that students talented in dance, music, art and sports do not require special school programs, since their talents will be nurtured enough by extracurricular activities. It also suggested that students below age 17 not be allowed to accelerate, at least for the time being. Acceleration in elementary and junior high is strictly prohibited since grade skipping may provoke severe competition for college entrance.

#### Admission to College

In 1991, the CCE report discussed modifications to the university entrance requirements that might foster the development of students with special talents and interests. Screening of accelerated students should be based on various data. Some universities, like Cheeba University (1997, 1998), have accepted the proposals and employed such methods as recommendations from teachers, experiments, essay, interview, and performance to identify those who are talented in math and physics.

In an effort to provide various experiences for gifted high school students, a pilot project was launched, which allows them to participate in lectures and seminars hosted by universities or private institutes.

#### *Problems and Perspectives*

At last, Japanese officials have come to acknowledge the individual differences in academic achievement and special abilities among older students and have introduced a special policy for these students. However, considering Japanese contemporary philosophy and past educational practice, it may take some time before the Japanese school system provides enrichment programs for gifted students. According to Stevenson (1998) and Stevenson et al. (1992), enrichment programs for gifted youngsters are unlikely to flourish in a culture where elementary school teachers are reluctant to tell parents that their child is gifted or academically advanced and where direct forms of teaching in nursery schools and kindergarten are avoided. This attitude is rooted in a belief that ability is not inherent, but rather the result of practice and hard work, even at the youngest age. That is, "Work hard, then you can achieve better." Japanese people believe that the individual differences, even at the fetus stage, are influenced by the environment and one's efforts rather than by innate, stable, and fixed characteristics. Therefore, they believe that the government should not enhance individual differences by intentionally providing special programs for those who are already doing well. Gifted education will be the responsibility of motivated parents who will provide special programs for their children through private lessons.

#### **Korea**

Rapid development of GATE has occurred in Korea. GATE programs in Korea can be characterized by a variety of approaches: special high schools for the gifted and talented, after-school enrichment programs in elementary and junior high schools, acceleration, enrichment programs provided by gifted education centers affiliated with school boards and universities, and the newly established cyber gifted education system.

In Korea GATE started in 1983 with the establishment of the Science High School. Later, the government set up the *Research Center on the Education of the Gifted and Talented* at the *Korean Educational Development Institute* (RCEGT-KEDI) in preparation for formal introduction of GATE programs to regular schools from school year 2001 on.

#### *Programs*

##### Gifted Education in Special High Schools

As of 1999, in Korea there are 16 science high schools, 15 foreign language high schools, 15 sports high schools, 18 performing arts high schools, and a Korean

National University of Arts providing differentiated curricular for the gifted. These schools are equipped with advanced educational facilities. Except for the foreign language high schools, the teacher-student ratio is about 1:8, which is much lower than the 1:31 of ordinary high schools.

Junior high school students within the top 1% on relevant subjects or those who won significant competitions are qualified to apply for admission to Special High Schools. The students' GPA, award records, and physical conditions are all taken into account in the admission process. The paper-pencil tests, which had been used for a long time (from 1983 to 1997), have been recently abandoned in this process.

Special High Schools use a unique and customized curriculum. The curriculum is based on a non-graded and individualized instructional system of acceleration and enrichment. It is characterized by more advanced content in a specific field (e.g. more than 45% of the total units are allocated to subjects related to science and math in Science High School), more class hours for activities and performances, and more elective courses and individual studies, as compared to the regular high school curriculum.

##### After-School Enrichment Programs in Regular School

The 6th revision of the National Curriculum (1995) requires schools to provide gifted and talented students in regular schools with enrichment programs. Enrichment programs have been developed and disseminated to regular schools and gifted education teachers have been trained inside and outside Korea, by the *Ministry of Education of the Republic of Korea* (MOE) in collaboration with the *Korean Educational Development Institute* (KEDI), and by the *United Nations Development Programme* (UNDP) in 1990–1994. About 9.1% of elementary schools, 17.7% of junior high schools and 8.3% of regular senior high schools provide enrichment programs during after-school hours in various subjects such as science, maths, music, dance, foreign languages, and arts (Cho & Kim, 1994; Cho & Oh, 1998).

##### Acceleration

In 1995, the government revised the education law allowing students to skip grades. This policy has been implemented since 1996, thus gifted students with outstanding academic achievement can enter elementary schools at an earlier age, skip selected grades, be promoted earlier to the next school level. All schools are entitled to identify these students through careful evaluation for acceleration upon parent's agreement. In fact, however, there were only few students who wanted to be accelerated for the reason that it might result in lower academic achievement in the long term. Currently early admission to elementary school is the only option being pursued by parents and pupils.

### Gifted Education Centers Affiliated With School Boards And Universities

Sixty three school boards (32.47%) provide enrichment programs for gifted elementary and/or high school students for the time being (Cho & Oh, 1998). In addition, the Ministry of Science and Technology supports 9 universities which provide after-school enrichment programs for gifted junior high school students. It is expected that the number of universities which provide enrichment programs will be increased to 13 in the year 2000.

### Cyber Gifted Education System

The cyber gifted education system was established in 1998 to provide enrichment programs on the web for those who live in remote locations. Currently, there are two systems: one for gifted students in elementary school (<http://gifted.kedi.re.kr>), which is operated by KEDI (Cho & Park, 1998); the other for gifted junior high school students, which is operated by the *Korea Advanced Institute of Science and Technology* (KAIST). These systems will add more courseware in coming years and schools which are not equipped with trained teachers may want to use the systems.

### Private Institutions

There are also private institutions that provide enrichment programs for young gifted children. One of the most recognized is the Korea Academy of Gifted Education affiliated with the CBS Cultural Center. It provides enrichment programs to nurture creative problem solving abilities of children from age 3 to the junior high school level. In addition, Korean Minjok Leadership Academy, a private high school, was established in 1996, with the goal of training leadership skills of gifted youths. It provides academically and personally challenging programs.

### Problems and Perspectives

There are two main obstacles in nurturing gifted children. One is the university entrance examination, which is mainly a one-shot affair. The other is the insufficient support given to schools with GATE programs, especially in the form of legislation.

In Korea, entering a top university is often viewed by parents and students as a chief criterion of academic achievement (Cho, 1991). Over preparation for this one-shot exam has a negative effect on students' creativity and talent development. In an effort to both boost the creativity of special high school graduates, especially those from science high schools and guarantee the autonomy of universities, the government has established a new university admission policy, focusing on a diversity of entrance requirements rather than the exam. This policy will be implemented in 2001. In the near future, teaching and learning at science high schools will focus more on the development of

student's individual aptitudes and talents and less on entrance exam preparations.

Fortunately, the Korean Parliament has just passed the Gifted Education Law (1999) that defines the responsibilities of schools, school boards, and the central government in providing GATE programs from grade 2 to grade 12. When implemented in the near future, it will create a solid foundation for better teacher training and provision of GATE programs as an integrate part of regular school education.

### Philippines

The Philippines started its gifted and talented programs earlier than other Asian countries. The earliest seed was planted in 1966 with the opening of the Teacher Training Program for the Gifted in the Department of Special Education, University of Philippines. An official commitment to GATE was written into the 1987 Constitution. Currently, there are 3 high schools devoted to students talented in either arts or science and there are some gifted programs offered by regular schools. Two private organizations, the *Talented and Gifted Philippines* (TAG Philippines) and the *Gifted Philippines, Inc.* (GPI), are committed to promoting and developing education for the gifted and talented.

### Identification

The procedure for identifying gifted/talented students relies on a combination of assessments, including standardized tests, classroom grades, teacher recommendations, and interviews with parents and students. For science high schools and arts high schools, the screening criteria are stricter and more relevant to their specific field of talents (Roldan, 1992).

### Programs

Since the formal provision of GATE still remains rare in the Philippines, the top challenge in meeting the special needs of gifted and talented children is making use of limited resources. The Manila Science High School and the Philippine Science High School were set up as early in 1963 and 1964 respectively. Both schools provide challenging programs and, each year, select the 'cream of the crop' of young scientific minds from around the country. Scholarships are offered to deserving but underprivileged students and, recently, these schools have branched out to different regions of the country (Roldan, 1992).

Another prestigious special school is the National High School for the Arts. This institution trains promising young artists in music, dance and the visual and performing arts, while at the same time providing them with a complete secondary academic education. Student selection is again very strict and covers all regions of the country (Roldan, 1992).

The private Reading Dynamics Center, founded by the reading specialist Dr. Aurora H. Roldan, has hosted

an annual Children's Festival of Words since 1973. The Festival is actually a creative writing workshop for verbally gifted children. It is gradually evolving into a vehicle for identifying children who are not only intellectually and verbally gifted, but also talented in other areas. It also resulted in the birth of TAG Philippines in 1983. This organization provides a support group for gifted young children and their families. Today, TAG not only provides identification and assessment measures for a variety of areas in giftedness, but also offers advice to parents, as well as to the gifted themselves.

The GPI, on the other hand, strives to promote and develop the general welfare of gifted, talented, and creative children, youths and adults. The GPI sponsors teacher training, seminars, workshops, and research projects.

#### *Problems and Perspectives*

Being greatly influenced by America, the Philippines' GATE has been in a state of gestation for over three decades. Gifted education, however, has not made great advancements during the last three decades. Due to the unfortunate political situation and economic development, the government's investment in education has been too limited to support GATE in public schools. Consequently, civic groups and business entities are currently the chief advocates for GATE. Nonetheless, it is still written in the constitution that all opportunities should be taken to develop the potentials of children.

TAG Philippines has recently changed its philosophy and now focuses on developing the critical and creative thinking of all students, not just the gifted (TAG Philippines Newsletter, 1997). This change grows from the belief that fostering giftedness depends on making students aware of their hidden power and talents and teaching them how to use these aptitudes to assist humankind.

#### **Singapore**

Gifted education in Singapore basically takes one of two forms: the *Gifted Education Program* (GEP) or the Science Research Program that are governed by the Gifted Education Unit, Ministry of Education (Singapore Ministry of Education, 1999). GEP was first implemented in 1984 and its programs cater to the needs of the intellectually gifted. Its programs fall mainly into two categories: Self-contained classes and pull-out programs. GEP does not cover music or art areas, for which there are specific programs such as the Music Elective Programs and the Art Elective Programs. Schools that provide GEP have been increasing every year. It has currently expanded to 9 primary schools and 6 secondary schools, including the notable Raffles Institution and Chinese High School, both of the independent schools that had been given autonomy in staff development and salaries, finance, management

and curriculum, while continuing to enjoy substantial government support (Lim, 1999).

#### *Identification*

For self-contained GEP classes, all grade 3 pupils are invited to sit for a Screening Test in English Language and Mathematics. In the end, about 400 students (0.8%) are selected based on their test scores on language ability, numerical ability and general ability. These students are then placed in a GEP program starting with Grade 4. After completing a 3-year primary program, they are then promoted to a 4-year secondary program. Promotion is not automatic. Students are screened on the basis of their primary GEP performance, their attitude towards GEP work, and the results of *Primary School Leaving Examination* (PSLE). A second supplementary entry point into the GEP occurs at Secondary 1 (Grade 7). About 100 students are selected among those who have scored 3 or more A's in the PSLE and have taken the Language Ability, Numerical Ability and General Ability Tests. For pull-out GEP classes, about 25 Secondary students are selected from among 300 Chinese High School students on the basis of their general ability, numerical skills and logic skills (Singapore Ministry of Education, 1999).

#### *Programs*

The GPE in Singapore seeks to meet the intellectual needs of the gifted through the provision of an enriched curriculum within a stimulating and interactive environment. The 7th World Congress on Thinking held in Singapore in 1997 attracted the whole country's attention. Many scholars of great renown attended and over 3,000 educators from all around the world participated. This conference was considered very productive and strengthened the country's goal of a 'Thinking School and Learning Nation'. GATE thus became one of the top priorities in national development.

The GATE program in Singapore is essentially one of enrichment rather than acceleration, and of self-contained classes in regular schools, rather than gifted schools (Lim, 1997, 1999). Self-contained classes are kept small with about 25 students. Students have the opportunity to interact with other students through various extra programs. Teachers are specifically selected and trained. Whenever possible, the GE Branch recruits suitable teachers from among the mainstream teachers in the GEP schools. A major part of the GEP teachers' training takes place on the job through supervision and regular meetings with GE Branch officers on matters relating to GEP curriculum and teaching strategies (Singapore Ministry of Education, 1999).

The self-contained GEP classes are essentially enrichment programs, based upon the national curricu-

lum, carried on during regular class hours. In the GEP, topics are dealt with in greater depth and breadth. Greater emphasis is placed on the development of creativity as well as projects. Students also have the opportunity to work with specialists in creative writing, the humanities and the sciences through mentoring programs. Besides developing the intellectual capacities of students, GEP is also concerned with developing students who are active and responsible citizens. This is accomplished through an enriched Civics & Moral Education curriculum, which emphasizes self-awareness, social awareness and community involvement (Singapore Ministry of Education, 1999).

The pull-out program provides a challenging and enriching curriculum in Mathematics, Science and Computer Studies. In addition, individualized projects, which involve an interdisciplinary approach and the participation of university and professional mentors, are also encouraged. Creative computing programs are also provided to develop students' abilities to simulate real-life situations and write programs.

GEP students sit for the PSLE and GCE 'O' Level examination just like any other student. However, for both of these national examinations, they are tested in an additional subject (e.g. Social Studies in the case of the PSLE and one additional elective subject for the 'O' Level Examination).

In addition, the MOE Gifted Education Unit collaborates with the National University of Singapore in organizing special programs such as the Science Research Program, the Creative Arts Program and the Humanities and Social Sciences Research Program. These programs are open to all first-year junior College (grade 11) students and not just former GEP students.

#### *Problems and Perspectives*

During the last 15 years, GATE in Singapore has made great advancements in terms of the number of students attending special programs and the diversity of the special programs offered. However, teachers should do more to extend and fully cover the syllabus for fully challenging the gifted and talented students. There is also a need to make non-program teachers more aware of the characteristics and needs of gifted and talented students.

#### **Taiwan**

The development of GATE in Taiwan can be divided into four stages: The dawning stage before 1973, the initial experimental stage (1973–1979), the extended experimental stage (1979–1984), and the promoting stage (after 1984) (Wang, 1992; Wu, 2000b).

The framework of GATE in Taiwan is best understood through an analysis of the operational system, which can be broken down into three levels: the implementation level, the supervisory level, and the resource level (Wang, 1992). The implementation level

includes identification and placement of the gifted/talented, curriculum, teaching materials and teaching methods, and the teaching staff. The supervisory systems involve policy and legislation, administrative organizations, and guidance and research. The resource level consists of parental involvement, community resources, and private organizations. The *Special Education Law* (SEL) passed in 1984 (revised in 1997), where GATE was incorporated into all levels of schooling along with education for the disabled, is a milestone and guidepost of GATE development in Taiwan. The SEL sets policy directions for the special education system, curriculum design, teacher development, and resources (Wu, 2000b).

#### *Identification*

The identification procedure of gifted/talented students in Taiwan is very strict and systematic, based on multi-assessment and step-by-step screening process (Wu & Cho, 1993; Wu, 2000b). In those classes set up for the intellectually gifted, candidates are first screened by the school itself through group intelligence tests, students' daily performances, and teachers' observations. Then a series of group and individual standardized tests are administered to the upper 10% screened as potential candidates. According to the new regulations, the students finally selected must meet the criteria of high IQ and high grade point average (scores higher than 1.5 standard deviations above the mean are usually required). To be enrolled in the programs for the mathematically/scientifically talented, one must either have a score higher than 1.5 standard deviations above the mean on achievement tests in math and/or science, a grade point average in the top 1% of their school peers at the same grade in maths or science, or demonstrate an outstanding performance in a national or international competition. For the linguistically talented program, the criteria and procedure of identification basically follow that of mathematics and science (Wu, 2000b).

For the special classes for the artistically and musically talented, students are assessed through their performance in fine arts, on musical instruments and through a series of artistic or musical aptitude tests. The eligibility criterion for students talented in dance and drama is mainly focused on performance. Those who won awards for distinguished performance in a national or international contest are also accepted (Wu, 2000b).

It should be noted that the minimum requirement of an IQ test score above the mean for the talented in music, fine arts, dancing, drama, and sports, which had been used for years, has been discarded in the revised SEL of 1997.

Once students have been tentatively identified as gifted or talented, a committee made up of teachers and administrators from the student's school submits a report to the local department of education. After

further screening by the department, with the consultation of educational experts, qualified students are placed in appropriate special programs or classes.

### *Programs*

GATE programs implemented in Taiwan are mainly for students with high general ability, students talented in specific academic domains, and students talented in fine arts, music, dancing, drama, and sports. The goals of these programs are: (a) to develop the potential of gifted/talented students, (b) to cultivate good living habits and healthy personality traits, and (c) to teach for high cognitive and/or skill attainment (Ministry of Education, R.O.C., 1979, 1982; Wu, 1992).

Over the past three decades, GATE in Taiwan has expanded through a series of pilot programs. The greatest expansion was during the period of 1981 to 1992 (about 20% increase rate per year), in the last five years, the increase rate has declined to only about 3% per year (Wu, 2000a, 2000b). The 1998 educational statistics (Ministry of Education, R. O. C., 1999) showed that 484 schools, including 188 elementary, 174 junior high, and 122 senior high schools, were conducting programs for gifted and/or talented students. The total number of classes reached 1,422, with 37,225 students. It is estimated that one percent of the total student population were being served in these programs (Wu, 2000a). In addition to special classes and pull-out programs, which emphasize enrichment, there are some acceleration programs for highly gifted students in Taiwan. According to the published measures, they can adopt such means as early entrance, grade-skipping, early graduation, telescoping grades, advanced placement, and exemption from entrance examination, to complete their academic years. According to the new SEL (1997), students who are deemed to be generally gifted and distinguish themselves in all areas of study are allowed to accelerate one year (or more in special cases) in elementary, junior or senior high school.

Additionally, the students identified as being talented in math, science, Chinese, or English, also have the opportunity to take part in special camp programs conducted by universities. Alternatively, they may be qualified to bypass the university entrance examination and be directly admitted to universities majoring in pure sciences, such as physics, chemistry, and maths, or Chinese/English departments.

Program design for gifted students is handled on several levels. Basically, the central government sets goals for the curricula, while the local schools develop specific programs and experimental classes in collaboration with colleges and universities. Recent topics have focused on various enrichment programs, evaluation methods, and follow-up studies on gifted students' development (Wu, 1992, 2000b). Flexible teaching methods, such as peer-tutoring, debate, discussion, brainstorming, experiment, independent study, drama,

contest, and game are employed to stimulate student's creativity and problem-solving ability.

In addition to enrichment of the cognitive domain, affective development is another important component of gifted education. A peer-assisted program entitled 'the caring peer-tutor system' is a good example. In this system, gifted students provide their poorly achieving peers with assistance in academic work. Consequently, gifted children develop not only a gifted mind but, more importantly, a tender and loving heart (Wu, 1992).

### *Problems and Perspectives*

Because the opportunity to be selected in the GATE program is limited, the identification procedure is often viewed as competitive by parents and teachers. To be fair, standardized tests rather than observations and/or performance are emphasized. As a result, very few socially/culturally diverse students are admitted to the GATE program simply because of their limited access to mainstreamed culture, on which the tests are based.

Another identification problem concerns under-achieving students with high IQs. Every gifted class has such students, and the teachers complain that it is difficult (if not impossible) to remove them from the class. Rimm (1997) feels that the underachievement of gifted students is a national epidemic (in the USA), and from the research data of Campbell & Wu (1998), it is likely that it is an international epidemic.

In recent years, more educators and administrators are advocating the resource room model as an alternative approach to special class. Among the arguments in favor of mainstreaming the gifted, the focus is on the affective/social domains. A continued expansion of resource rooms for the intellectually gifted children—but not for the talented—has occurred in recent years. Both models, the special class and the resource room (or pull-out program), have their advantages and disadvantages. The decision on the relative efficacy and desirability of each model is still an unsolved problem (Wu, 1992, 2000b).

Another unique condition in Taiwan is the attitude of parents toward gifted/talented education during the junior high years. Many parents are preoccupied with the idea that entering the best senior high school is the most important thing for their children. They feel anxious if the gifted/talented classes have too much curriculum content that is outside the scope of the 'standard curricula' or the high school entrance exam. This perception puts inordinate pressure on the schools, and influences the teaching of gifted/talented classes. Accordingly, many teachers think that teaching the gifted is more of a challenge and more stressful. They also caution against having unrealistic expectations for the gifted (Campbell & Wu, 1998).

In accordance with the nationwide educational reform movement, gifted/talented education in Taiwan is confronted with the following challenges: (a) to

design a student-centered, school-based, and professional-oriented educational program; (b) to identify and nurture the talents of the disabled and the culturally and behaviorally diverse; (c) to bring creative thinking into school reform; (d) to cultivate student's practical competency and vitality through multiple and flexible school entrance systems; (e) to upgrade education quality by developing and sharing educational resources; (f) to create a lifelong learning society by strengthening career planning and follow-up services, and (g) to moderate a conducive ecological environment for the full development of each student's potential (Wu, 1998).

### Thailand

Only in the past two decades has research on the gifted and talented in Thailand been carried out in various areas of interest, focusing on teaching strategies, modeling, public attitude, and program efficiency. However, these may not be coordinated or related to the needs of GATE in Thailand (Photisuk, 1999). In the sense of practice, GATE in Thailand is just beginning. A national policy has yet to be established regarding GATE. There have been limited opportunities for gifted/talented students to participate in an enriched or in-depth study, outside of what is already stipulated in the curriculum.

Since 1980, recognition of the educational needs of gifted/talented children has increased and a small number of educators have become interested in providing differentiated educational programs for the gifted and talented. The increasing concern recently resulted in the establishment of the National Center for the Gifted and Talented in 1999, which will focus on developing policy and a national plan regarding GATE and support the set-up of the National Research and Development Institute (Phothisuk, 1999).

### Programs

There are three major organizations that work in different areas of GATE in Thailand. They are: the Foundation for the Promotion of Gifted Children, the Department of Special Education of the Srinakharinwirot University, and the Institute for the Promotion of Teaching Science and Technology (Sunhachawee, Promboon & Phothisck, 1992).

The Foundation for the Promotion of Gifted Children, associated with the Department of Special Education, Srinakharinwirot University, provides once-a-year trainings for parents and teachers involved in summer programs in arts and creative writing for young children and in science for gifted high school students. The Foundation also collaborates with 10 schools and universities to prepare reading materials for students and teaching materials for teachers, in the GATE program.

The Department of Special Education, Srinakharinwirot University, has offered a M.Ed. program in

GATE since 1991. The Institute for the Promotion of Teaching Science and Technology works on the following projects:

- (1) The Long-term Scholarship Project, which started in 1984, grants full government scholarships to outstanding high school and undergraduate students. This continues throughout their school and college years until they receive Ph. D. degrees and become scientists. Those who graduate are guaranteed positions in government organizations, mainly in research and development sections or in universities' schools of science, though. Six high schools and 6 Thai universities, constituting 6 pairs of school-university cooperative units, are participating in this project.
- (2) The National Science and Mathematics Olympiads project was formally started in 1991. Under the government's full support, this project charters an annual selection and training of high school students to compete in 5 international Science and Math Olympiads, i.e. Maths, Chemistry, Biology, Physics, and Informatics. The Royal Thai Government sponsored the 6th International Biology Olympiad in 1995 and offered 15 full scholarships to the finalists in National Olympiads for long-term study from 1993.

The proposed *National Research and Development Institute* (NRDI), supported by the National Education Committee, will have the following responsibilities pertaining to GATE (Phothisck, 1999):

- Master plan for research and development in GATE.
- Follow-up research projects.
- Coordination and knowledge and experiences sharing with other research
- organizations in GATE, both in domestic and overseas.
- Center for the body of knowledge in GATE.
- Center for resources in GATE.

The NRDI's short-term action plans include the development of identification instruments and the implementation of GATE in accordance with the Education Act, which has been in effect since August 19, 1999. Its long-term plans include expansion of research areas and the accountability evaluation of research projects.

### Problems and Perspectives

Despite the fact that there are a number of national projects to enhance giftedness and talents among Thai children and youth, most projects are oriented toward scholarships and competitions or contests only. This results in a very limited number of children who are served in special education programs.

Thailand is in need of more experts in this area to design and develop educational infrastructure aimed at the identification and development of gifted/talented

children at early ages. With the newly established National Center for the Gifted and Talented, it is expected that there will be more research, activities and programs for the gifted and talented and, in the near future, a well-defined national policy for GATE in Thailand

### **Summary and Conclusions**

The main factors contributing to the development of GATE in Asia are: the educational philosophy of emphasizing teaching according to individual differences, the societal tendency to value intellectuals and the wise, the principle of governing a nation on the basis of employing the talented, the needs of economic development, the emphasis of children's education by the parents, and the consideration of human power planning by the government (Wu, 1998).

Regarding identification issues, it is hoped that multi-criterion and alternatives other than standardized intelligence tests can be adopted. As the conception of giftedness is broadening and GATE programs are expanding, the identification/assessment procedures will change into a less strict and more flexible system, aimed at developing talents for all.

Programs for gifted and talented children in Asia are new, with the majority having been established during the last one or two decades. The most vigorous efforts are being made in Taiwan, Korea, and Singapore, where the governments have introduced a wide variety of programs for gifted/talented students during the regular school day as well as after school. Elsewhere on the other hand, Japan supports no programs specifically for gifted/talented students prior to the high school years. In India, Indonesia, the Philippines, and Thailand, GATE is mainly operated by private agencies and/or on a small scale.

Political philosophy is obviously not a critical factor in determining whether programs for gifted/talented students will be established (Stevenson et al., 1992; Wu & Cho, 1993). A typical example is Japan. Japan had bitter experience with social elitism before World War II and since then has taken vigorous steps to avoid the emergence of groups that would dominate the political and social life of the country (Hirano, 1992). As a result, Japan makes strong efforts to ensure that all children begin school with equal knowledge and receive equal educational opportunities during their compulsory education years. It was after 1997, that the Japanese government decided to allow limited 'exceptions' in the procedure of entering a university and curriculum flexibility at senior high and college levels (Japan Central Council for Education, 1997).

It appears that neither the level of economic development nor the quality of schools and universities determines whether or not programs for the education of gifted and talented students will be established in any particular country. The critical difference is the culture's philosophy of education (Stevenson, 1998;

Stevenson et al., 1992). In an effort to promote egalitarianism, all the elementary school students in Japan are required to remain with their classmates regardless of their level of intelligence or of academic achievement. In contrast, some countries mentioned in this article, seeking to enhance the contribution of gifted and talented students to their societies, have developed elaborate programs of special education. The natural experiments taking place in these cultures will provide information about gifted and talented students that will be of interest throughout the world (Stevenson et al., 1992).

It is obvious that some countries in the Asian region are not so blessed as to have official state backing for gifted education. In some, the gifted are lumped together under the rubric 'exceptional children' which includes the handicapped. In others, gifted education is a matter of organizational commitment. There is, to be sure, the perennial problematic gap between rhetoric and action, as well as between policy and implementation (Roldan, 1992).

In the overview of GATE worldwide, Passow (1985) gave two reasons for excluding the United States. His reasons were (a) because the diversity of practice is so great and (b) because anything found elsewhere in the world can be found somewhere in the United States. The converse may give a better picture of the reality; practically all programs and curricula for the gifted and talented in Asia have been modeled, if not outrightly transplanted, from somewhere in the West. There is nothing essentially wrong with borrowing from other cultures; however, we should pause to look more closely at what and how we borrow. There are indications in the 1992 Asian survey (Roldan, 1992), that a distinct curriculum for the gifted, different from the regular school curriculum, has made its appearance on the Asian scene.

It seems that, with the acceptance of a differentiated and distinct curriculum for the gifted, rather than merely enrichment or acceleration, the question of the goals of GATE in the Asian area becomes an acute one (Roldan, 1992). Admittedly, Asian countries are at different levels of development and, therefore, are at different levels in their capacity to help gifted/talented children; but it may be at this point where the pooling of expertise and resources becomes important.

In sum, GATE in Asia has made steady progress in the past and has a promising future. Further development should be planned and implemented. To ensure the full development of talents in our society, we must not be content with the limited programs in limited areas on an experimental basis. Multi-flexible GATE programs ought to be designed to meet the divergent needs of the students with multi-capabilities. As Asian countries gain knowledge and experience with GATE, it is hoped that we can continue to improve education for all as well. According to the claim of educational

reform in the Asian region, GATE is facing a number of challenges. It is also hoped that GATE will be a leading force in educational reform, fostering the development of modern society and the welfare of all humankind (Wu, 1998).

# Programs and Practices for Identifying and Nurturing Giftedness and Talent in Australia and New Zealand

Eddie J. Braggett<sup>1</sup> and Roger I. Moltzen<sup>2</sup>

## Introduction

The last quarter of the twentieth century witnessed significant advances in the recognition and education of gifted and talented persons in Australia and New Zealand. These advances stemmed from the increasing realisation of the need to provide for innate giftedness and the necessity of developing high level talent. The eight Australian states and New Zealand (collectively known as *Australasia*) grappled with the concept of giftedness within their egalitarian social systems, seeking to provide for individuality and excellence but striving to avoid the disparaging claims of elitism and privilege. The responses of the two countries varied, as did the reactions of the separate states within Australia, often reflecting the direction of the educational leadership, the strength of lobby groups in society, and the ideologies of prevailing political factions. The following account analyses the ebb and flow of these educational currents under five headings: (1) the influence of egalitarianism, (2) recent influences, (3) state and national policies, (4) educational provisions, (5) research, and (6) future issues.

## The Influence of Egalitarianism

In the first half of the twentieth century, Australian and New Zealand education was developed with twin purposes in mind, viz. to provide mass education for students until 14 or 15 years of age and to taper provision for a minority of senior students who aspired to university or college study. Primary education was comprehensive by nature and, with the exception of three Australian states in which a few special classes were provided for selected gifted students (Braggett,

1985), no attempt was made to single out those with ability or potential. In contrast, secondary education in both countries was academically oriented and geared to university entrance requirements while, in New Zealand, streaming (or grouping) was widely implemented based on standardised testing—primarily intelligence testing.

The second half of the century witnessed the rapid expansion of secondary education as student numbers swelled, as retention rates increased, and as an increasing percentage aspired to post-secondary education. This resulted from a changing society in which extended secondary education was deemed to be appropriate for most students and in which the goals of schooling were constantly re-moulded. In a flurry of reform in the 1960s and 1970s, schools were called upon to provide for the full span of intellectual abilities, social (or age) groupings proved popular, and teachers were required to cope with a new breed of students from socioeconomic groups not previously encountered in the senior years of the school system. Teachers were expected to react quickly and positively to the new demands of a rapidly evolving society.

The practice of streaming was increasingly criticised in both countries as being elitist, critics pointing to the disproportionate number of Maori and Aboriginal children who were placed in lower streams. Moreover, the widespread use of intelligence testing was criticised as educators questioned its validity in a modern egalitarian society. Consequently, the school gradually broadened its curriculum, became less selective, and assumed a social function not formerly acknowledged. Comprehensive schools replaced selective schools in some systems, core curricula were developed, elective studies were introduced, teaching was pitched at an average level, and staff were required to provide for so-called disadvantaged groups in a multi-cultural society, an ill-defined role but one aimed at social reconstruction (Braggett, 1985).

<sup>1</sup> Charles Sturt University, New South Wales, Australia.

<sup>2</sup> The University of Waikato, New Zealand.

During the period 1950 to 1980, schools sought to provide more equitably for a wide range of students but unfortunately the needs of the academically and artistically inclined were often downplayed. Resources were required to assist other students with special needs and it was not always believed that gifted students were included in this category. In its starkest form, the issue was seen in terms of alternatives: education could concentrate on those with special needs (the disadvantaged) or on those with special abilities. Society could develop comprehensive schools for all or provide differentially for separate groups. In the spirit of the time, the balance was tilted in favour of those with special needs, often to the neglect of the gifted/talented (Braggett, 1985) or those with special abilities (Moltzen, 1996).

By 1975 a growing reaction was apparent from a variety of educational groups and from concerned parents who believed that more appropriate provision was required for gifted students. At least three New Zealand publications in the 1960s had concentrated on gifted children and these were followed by *Children with special abilities* (NZ Department of Education, 1972), a handbook which brought together much of the earlier thinking. Within Australia, questions were posed in Western Australia, New South Wales, and Victoria, exploring the needs of able students and the type of education required for them. Hence, when a World Conference on Gifted Children was convened in London in 1975, the two countries sent more than 30 delegates, and Professor Parkyn (1976) from New Zealand provided a keynote address on the *Identification and evaluation of gifted children*.

It is now more than 25 years since the gifted movement surfaced, a period in which the two countries have sought to provide for gifted people in their individual ways. There are similarities between the two countries in terms of heritage but no common approach to gifted education has emerged and none is likely because of the diverse nature of the educational systems and the geographical distances involved. The Australian population of almost 20 million is scattered over a large continent equal in size to mainland USA, the majority being found on the coastal strip with a preponderance in the south-east sector. Because education is a state right, Australia has eight distinct educational systems with different organisational structures, system networks, and curriculum development processes, and all are underpinned by political ideologies of varying shades. Twenty-eight percent of Australian students are taught within church and private schools which have an additional degree of independence. New Zealand lies 2000 kms across the Tasman Ocean to the south-east of Australia, a land of geographical contrasts ranging from pastoral plains to rugged alps and glacial rivers. Within this small country of 270,000 km<sup>2</sup>, an area smaller than Italy and equal in size to the state of Colorado, the population of

3.4 million has developed a single (national) system of education in which there is considerable devolution of responsibility to the local school.

### Recent Influences

During the 1980s and 1990s, there were three major influences that were common to both countries and which influenced educational provision for gifted students. The first was an egalitarian outlook that sought to promote social justice, to remove handicaps, and to develop welfare systems for those in need. In New Zealand, for example, the Ministry of Education sought to remove barriers to achievement, to break down cultural stereotypes that inhibited performance among minority groups, and to develop teacher awareness of the need to cater for a wide range of academic and social behaviours within the school. The NZ Education Act of 1989 decreed that "equity objectives shall underpin all activities within the school," and referred specifically to Maori, Pacific Islands, and other ethnic groups as well as women and girls, students with disabilities, and students with special learning needs (NZ National Education Guidelines, 1990). In Australia, likewise, there was a strong political and educational concern with issues of equity, particularly those that concerned Indigenous students (i.e. Torres Strait Islanders and Aborigines), girls, those with disabilities, students from non-English speaking backgrounds (referred to as NESB students), and those who resided in remote areas.

While it may be argued that gifted education is itself an equity issue, this has not always been accepted by politicians or educators in Australasia. It is often asserted, for example, that students with special abilities do not require assistance beyond that provided by the comprehensive primary or secondary school and that additional provision is tantamount to unwarranted privilege. As a consequence, it is felt to be elitist to identify gifted students and to provide for them in a differential manner: this, it is argued, discriminates even further against those with readily-perceived needs in society. There is little realisation that giftedness is culturally based, that talent is developmental in nature, and that both are intricately related to motivation, self-confidence, interest and sustained effort.

It is difficult to convey the egalitarian sense that permeated Australasian society during the 1980s and 1990s; neither should it be considered a necessarily negative phenomenon. Social justice was—and still is—a very real issue and, despite criticisms that have been levelled against governments in both countries, social attitudes have been modified, less advantaged groups have been assisted, and barriers to achievement have been removed. Those who succeed are now likely to receive genuine approbation, particularly when they overcome obstacles on the way to their success. On the other hand, too much success may engender resentment and lead to the *tall poppy syndrome*: very tall

poppies should be cut down (except when sport is involved).

Second, beliefs about giftedness and its definition have been modified over the past two decades. Giftedness was originally seen as an innate quality, relatively fixed, and deserving of provision in special classes or schools. When groups of school students were identified and given the tag of *gifted*, it was usually found that they were drawn from the dominant white society, from the educated middle-class, and from those with positive attitudes to education. Identification techniques were biased against those with different values, against minority groups, and against those who achieved poorly when standardised testing procedures were employed. In one sense, the equity issues referred to above, forced educators to explore more critically the concept of giftedness and its relationship to the culture, leading to a broader concept that was more amenable to education, coaching, or training. More emphasis was placed on developed ability (ie. on performance) and on the ways in which educators could facilitate the development of talent across different domains. The writings of Gardner (1983; 1993) and Lazear (1994) were influential in broadening the approach, including the need to cater for different learning styles.

As a result, increasing emphasis was placed on the comprehensive school and the ability of the teacher to provide for gifted students within the regular classroom. There were moves to downplay the concept of *giftedness* as such and to use different terminology: the *talented*, the *highly able*, or—as favoured in New Zealand—*children with special abilities*. It was increasingly accepted that teachers might influence the development of talent by differentiating the curriculum, varying their teaching strategies, emphasising the teaching of skills and strategies, and modifying their own classroom management practices. While this movement has been generally accepted in both countries and has resulted in very positive gains, there is also a danger that teachers may lose a sense of direction as they develop ‘the gifts and talents of all students’ and pay less attention to the most advanced students, to those with high potential, and to those with extraordinary abilities. It seems that the greatest success is achieved when a balance between these two approaches is preserved.

Third, there has been a relationship between the political ideology espoused and the degree to which giftedness has been specifically targeted and provided for within government schools. This has been particularly true in Australia where political parties with social democratic traditions have tended to favour policies aimed at equalising social outcomes and overcoming social barriers. While resource teachers have assisted students with learning difficulties, no comparable provision has been made for those with special abilities. The usual classroom setting and the

regular teacher, with some inservice or professional development assistance, are believed to afford the most appropriate education for gifted students and it is not accepted that the absence of special provision handicaps their development.

Political parties with a more conservative outlook, those geared to a free-market economy, and those with anti-Labor attitudes, have been more likely to favour wider choice and diversity of school provision. This has been pronounced in Australia where conservative governments have generally been more receptive to the gifted and talented cause and have adopted policies that have led to special schools, special classes, or additional training of staff.

Other political issues, however, have surfaced more recently to complicate the analysis described above. In New Zealand in the late 1980s and early 1990s the New Right ideology was responsible for a raft of public sector reforms. These changes reflected a general view that state intervention to promote egalitarian social goals had caused the economic problems of many western democracies. They embodied what Boston (1991, p.2) described as “an analytic framework grounded in public choice theory, managerialism and the new economics of organisations, most notably agency theory and transaction cost analysis.”

Australian politics in recent years have also reflected an economic rationalist approach in which the outcomes of education have been increasingly intertwined with the goals of the national economy. Funding to government schools has not kept pace with educational needs while concessions have been made to the private education sector. There is a perception in the minds of some that private/independent schools are more desirable and more likely to cater for academically advanced students, a result of their funding and the demands of their fee-paying parents.

At the same time, some labour-oriented political parties have recently modified their approach to educational provision. In New South Wales, for instance, the Labor Party has not only preserved special primary classes and selective secondary schools (both requiring the identification and selection of gifted students and the provision of special schools) but has also campaigned actively for their extension, especially in country regions. In 1989 the New Zealand government introduced the most radical changes in the administration of education seen in more than 100 years. These changes were consistent with the reform of other aspects of the public sector and were characterised by a significant devolution of responsibility and authority from the centre to individual learning institutions. New Zealand has never had a national policy on the education of its gifted students and commentators have variously described the country’s attention to its most able as weak, patchy and inconsistent. However, some direction had earlier been provided by the agencies that became disestablished, or

whose function excluded such guidance following the introduction of the reforms. This meant the initiative for provisions for gifted students after 1989 resided exclusively at the local school level. In the post-reform era, each school was required to operate within a charter, developed in consultation with its local community. The government required all charters to include clauses relating to such issues as curriculum, equity, and provisions for Maori students. There was no requirement to include content relating to provisions for gifted students. Consequently, what an individual school provides for these students is a direct reflection of the priority it is accorded by the school and its community.

It is within this ethos that gifted and talented programs should be gauged within Australia and New Zealand. There is an undoubted desire on both sides of the Tasman Ocean to widen the benefits of education, to promote high quality schooling within the regular classroom, and for teachers to cater for a wider range of abilities. This is generally conceived within a traditional lockstep method of organisation, however, in which the majority of children cover similar work in groups and do not explore too far from the pre-determined curriculum. As a consequence, some opposition is expressed when withdrawal groups, content or grade acceleration, special classes or differentiated programs are suggested. Some schools, regions and entire systems have accepted an egalitarian thrust and resisted demands for different forms of provision but others have forged ahead and introduced innovative and exciting programs that cater for individual needs.

In line with these advances, it is evident that major advances have been made within Australia and New Zealand over the past 20 years. There is decidedly less opposition to students with special abilities and educational consultants who visit schools report a deeper appreciation of the need to cater for a wider range of abilities/talents. There is some indication also that, when government (state) schools are involved, an increased level of teacher awareness is related to the existence of a publicised policy by the Minister or the State Department on the education of gifted/talented students.

## State and National Policies

### *Australia*

The eight Australian Departments or Ministries of Education have all developed State Policies that draw attention to the needs of gifted students and to the types of provisions that might be made. Each provides a short rationale, a general definition of giftedness/talent, approaches to identification, ways of differentiating provision, programs available at state level, lists of

resources, contact persons, and—sometimes—sources of funding. It is informative to peruse these policy statements, beginning in 1979, as they reflect changing attitudes to giftedness and pinpoint considerable differences in the extent of each state's commitment to gifted education.

In the 1980s, Western Australia adopted the most radical of all policies based on a pyramid-type structure. Programs for the lower primary years (ages 5–8) were school based and designed to cater for approximately 5% of the age group; at the middle primary level (ages 8–10), 3% of children were selected for part-time withdrawal programs in strategically chosen schools with *special interest centres*; and, at the upper primary level (ages 10–12), classes were introduced for 2% of the children who were totally withdrawn for fast-paced scholastic courses but integrated with the rest of the school for expressive arts, physical education, and other informal activities. At the secondary level, approximately 1.5% were offered places in designated secondary schools where high calibre programs met their advanced intellectual needs while others attended secondary schools with specialities in such areas as music, dance/drama and languages (WA Policy, 1981).

It was maintained that this was a total approach to gifted education as it provided enrichment, extension and accelerated progression within the range of normal school options. An Academic Extension Branch was established at the state level, resources were committed, *talent searches* were conducted across the state each year, and professional development was provided for teachers. The purpose was to legitimatise and embed provision for gifted students within the mainstream of educational practice.

Most other states moved more cautiously and developed less radical policies, most being influenced by the Marland Report (1972) in which giftedness was conceived in a broadened form and by Renzulli's (1977) *Enrichment Triad Model* which was often used (but frequently misinterpreted) as the basis for in-class enrichment. An analysis of the policies developed by New South Wales, South Australia, Northern Territory, Queensland, Tasmania and the Australian Capital Territory (ACT) reveals a spectrum of provisions ranging from special schools/classes, regional consultants and centralised mentor programs at one end of the continuum to enrichment for able students in the regular class at the other end.

In the state of Victoria, enrichment and extension programs were provided on a cluster group basis (often involving both state and private schools), a mentor register was developed for the state, and one high school in Melbourne introduced a radically differentiated acceleration program in which students could complete six years of secondary education in four or five years. Victoria proved to be an early leader in gifted education (GCTF, 1983).

## Present State Policies

At the start of a new millenium, some Australian states are revising their policies once again in order to reflect changing views about giftedness and its development, and the desire to embrace more inclusive approaches. As explained in an earlier section, there is a strong thrust for the regular classroom teacher to be involved in program provision and for special classes to be de-emphasised. Moreover, the 1990s witnessed cut-backs in government expenditure resulting in financial pruning of educational services. Driven by educational and financial considerations, authorities questioned the need for separate programs and required the comprehensive school and the regular classroom teacher to assume increased responsibility for differentiated programs, often without any increase in resources.

At the commencement of 2000, all Australian states had policies relating to gifted and talented students: some were relatively general in nature while others reflected a system concern that led to quality program implementation. The main policy provisions, currently in effect, are outlined below.

- The strong thrust that earlier characterised Western Australia changed in some ways when responsibility for gifted education was transferred from the state's central office to the regional and district level. Nevertheless, the specialised secondary school programs continue and are genuinely entrenched within mainstream provision; the part-time PEAC withdrawal programs for primary children continue based on an annual state-wide *talent search*; and a range of school-based programs operate throughout the state. Staff professional development is stressed (Pears, 1999).
- Queensland stresses the need for extension, enrichment and acceleration at the school level and provides support through a state coordinator of gifted and talented education who has developed networks, provides inservice training, develops and distributes resources, and implements school programs and policies. Enrichment and extension concentrate on high-level skills development, creative and critical thinking and metacognition (Queensland Department of Education, 1993; Hewett, 1999).
- While stressing the need for school-based programs, South Australia also seeks to develop *Focus Schools* at the primary school level to act as models for other schools to emulate, to render support, and to provide professional development for teachers. Special Interest Secondary Schools are provided and supported in the areas of music, languages, agriculture, sports and SHIP (Students with *High Intellectual Potential*). Three full-time Coordinators work across the state, developing resources and providing support (SA State Policy, 1995; Minchin, 1999).
- Northern Territory, in addition to a system-wide identification program, provides special primary

school classes, permits accelerated progression, inservices teachers in enrichment strategies, and provides state-sponsored camps. Advanced senior secondary students may study a university subject in the final year of school, while the Aboriginal and Islander Tertiary Aspirations Program seeks to increase the number of Indigenous students who successfully complete secondary education and proceed to tertiary studies (Day, 1999).

- Tasmania reworked its policy in 1996 and committed funds for gifted education by assigning part-time coordinators in each of the state's districts and appointing a state-wide coordinator. Four special schools were designated in the areas of information technology, performing arts and off-site programs, while guidelines for early school entry and for acceleration were developed and trialled in 1998. In response to teacher needs, the new policy emphasises 'user friendly' identification and assessment procedures and outlines the development of a mentor program (Tasmania, 1996; Fagg, 1999).
- The Australian Capital Territory (ACT) is responsible for the smallest Australian system and the most compact geographically. Its 1998 draft policy placed emphasis on school-based programs and the development of students' skills. Strategies to provide for gifted and talented students included school and classroom grouping patterns, acceleration, workshops, and mentor programs (ACT Draft Policy, 1998).
- New South Wales is different from other states in that it provides Secondary Selective and Agricultural Schools and selective classes (termed OC Classes) in primary schools, entry to which is highly competitive. The number of such classes has increased over the last 10 years. Early entry to school is permitted and accelerated progression may take the form of year or content promotion. A Mentor Links Program has been developed as well as a Talent Development Project for students with outstanding talents in the field of popular entertainment. While school-based programs are emphasised, district network initiatives are promoted and have steadily increased over the past three years (NSW Government Strategy, 1991; Bradburn, 1999).
- The 1995 policy in Victoria places considerable stress on, and has led to the development of, statewide networks of schools and clusters of primary and secondary schools in particular curriculum areas; local gifted education networks; special programs to connect country schools; international programs; a diversity of programs to provide for Individual Learning Pathways; enrichment, extension, acceleration and mentor programs; a sustained and well coordinated central program aimed at resource development, school assistance, and teacher professional development; and a range of specific programs in concert with institutions, community

organisations and parent organisations. The approach has targeted teacher and public awareness and has included state and international conferences since 1995 (*Bright Futures*, 1995; Morris, 1999; Reynen, 1999; Stewart, 1999).

Private (independent) and Catholic schools are not part of wider systems and it is therefore difficult to refer to their policies as such. Each school may develop its own policy relating to gifted students and, as indicated in a later section, these range from general statements to those which are highly specific and which result in high quality, innovative programs.

Even though education is a state concern, the Australian Government has also been pressed to develop a *national* policy on gifted and talented education. A Senate Select Committee (1988) urged the Government to "make a clear statement that special educational strategies should be provided for gifted children throughout Australia" but this has not yet materialised, although there are current moves to influence and renew government interest (Geake, 1999).

#### *New Zealand*

New Zealand's history of providing for gifted students has been characterised by ebbs and flows of interest and attention, where positive developments have frequently resulted from the efforts of concerned individuals, and where gains have often been short-lived (Moltzen, 1996). During the 1980s there was a strong call from those committed to the gifted cause for a national policy, which would require schools to demonstrate the provision made for this group of students. It was argued that this would ensure consistency of provision and end a pattern whereby real progress was negated in the next era. This lobby group reminded educators that, among the countries represented in Sydney at the 8th World Conference on the Gifted and Talented in 1989, New Zealand was the only country without a policy on the education of the gifted (McAlpine, 1991).

At the same time there began a process of educational reform in New Zealand, characterised by decentralisation, devolution of responsibility, and increased parental choice. While the direction of reform reflected changes in other countries, New Zealand was committed to carrying the process much further than other educational jurisdictions. Lawton (1992), for example, reported in an international educational survey that New Zealand had taken decentralisation to a level beyond that of any other system studied.

According to the Ministry of Education, the post-reform environment in New Zealand has made the development of a national policy less appropriate than it has ever been. The principles of decentralisation and devolution mean that the chief educational authority

[the Centre] limits to a bare minimum the policies it imposes on local schools. While schools are required to develop policies in some areas, the gifted do not need such special consideration, the Ministry of Education defending its position by pointing to the country's recently-developed National Curriculum which is specifically designed to challenge "all students to fulfil their potential" (NZ Ministry of Education, 1991). This Curriculum advocates higher order thinking skills, open-ended activities, and problem solving approaches; contains achievement objectives across a range of levels covering 13 years of schooling; and encourages teachers to place students at levels commensurate with their ability, and not according to their age or grade level. To many, however, this provides an inadequate guarantee that the needs of the gifted will be met in an appropriate fashion. For example, the provision exists to accelerate the learning of the gifted but many teachers and principals remain reluctant to advance students beyond what is perceived as the level for the average child at a particular age and stage (Townsend, 1996). Where some acceleration is acceptable, any movement of a child in advance of his or her peers is likely to be very conservative indeed.

The arguments of the Ministry of Education when defending the lack of a national policy have failed to lessen the pressure for some national direction. In what could be interpreted as a response to increasing lobbying, the Ministry of Education in 1998 established an 'Advisory Group on Gifted Education' to advise the Ministry on issues associated with the education of the gifted. While the Ministry has held its position that a national policy is inappropriate, it has agreed with the Advisory Group's recommendation that national Guidelines be developed and distributed to every school in the country. The contract for this project has been let and these Guidelines are expected to be in all schools early in 2000. The Ministry has also agreed to fund a modest professional development program to accompany the distribution of the Guidelines and appears committed to exploring and supporting future developments for the gifted.

The Guidelines seek to provide schools with a platform on which to build their own policies and practices. The current educational climate in New Zealand emphasises the need for schools to work with their communities and to develop philosophies and approaches that reflect the needs of each individual community. Because the Guidelines will be required to reflect this principle, considerable variation is expected among schools as they define giftedness and seek to provide for their gifted students.

It is difficult to ascertain with accuracy the full nature of the influences that have resulted in this dramatic change of direction. It is 27 years since a similar initiative resulted in the publication of a booklet containing suggestions for teaching children with special abilities (NZ Department of Education, 1972).

There appears to be a greater appreciation of diversity and a weakening of the *one-size-fits-all* attitude, both inside and outside education. This is exemplified particularly in a variety of developments to improve the levels of Maori achievement. There is also an increased national awareness that New Zealand's collective attitude towards high achievement (except in sport) has been unjustifiably negative. It might be part of a developing maturity in a nation when the success of one group is not automatically interpreted as a threat to others. Perhaps it not inconsequential that New Zealand's preference for the term *children with special abilities* seems to have disappeared, allowing the national Guidelines to refer to these children as *gifted*.

### Educational Provisions

There is a wide diversity of provisions made for gifted and talented students at school, district and system levels throughout Australia and New Zealand. Moreover, terms such as *enrichment* and *extension* are often used interchangeably or with particular connotations that are specific to schools or to developed programs. Hence, the present analysis which includes some thousands of Australasian programs necessitates a conceptualisation that, while accurate, must be open to the charge of generality. The two countries are reported separately.

#### Australia

Seven types of provision may be discerned across Australia, involving individual schools, small clusters of schools, wider district initiatives, and overall system strategies.

#### Special Schools/Classes

During the first half of the twentieth century when high school education was a privilege for an intellectual elite, selective high schools became an important segment of secondary education in most Australian states. Designed for students with university aspirations, they were often single-sex schools and were located mainly in metropolitan areas. When secondary education was extended and reformed in the 1960s and 1970s, many of these academic schools were converted to comprehensive establishments and made co-educational in the process. A few, however, missed the reformers' zeal and were preserved as selective schools with competitive academic entrance requirements. During the 1990s, in a changing political scene, New South Wales once again increased the number of selective schools, so that 23 specifically cater for 'academically gifted and talented students' (Bradburn, 1999). These schools are renowned for their high academic results at the end of Year 12 when students sit for an external examination on which university selection is based. Except for a few selective establishments in Victoria, however, virtually all similar high

schools in Australia have been abolished. A Conservatorium High School exists in Sydney for talented musical students and is operated in conjunction with the NSW Conservatorium of Music.

With the growth of comprehensive secondary schools in the 1970s, it was found that gifted students were not always extended, and this resulted in two important modifications. First, extension courses were introduced into the senior years of the high school curriculum so that subjects might be studied at different levels of difficulty, a decision which assisted the academically capable. Second, the organisation of the high school itself came under scrutiny as alternatives within a comprehensive framework were canvassed.

Western Australia was one of the first states to react, introducing a Talent Search for students with high intellectual potential in the final year of the primary school, a scheme which continues to find favour with the community. On the basis of this quest, approximately 300 students are offered places in 10 comprehensive high schools, each having a special academic class which provides advanced courses and permits accelerated learners to work at their own pace. While each of the schools has developed its own approach, most place the students in a separate class for academic subjects for the first two or three years of their studies but require them to join regular classes for elective and non-elective studies.

One of the aims of these classes (and of the selective schools in New South Wales) has been to stem the drift of students to private schools because of the perception that independent schools might offer more academically rigorous programs. There is no doubt that selective schools/classes attract high quality students and enhance the academic reputation of the state systems.

Other states have introduced schemes to increase the academic orientation of the secondary school. Three South Australian secondary schools are designated SHIP schools (providing for Students with *High Intellectual Potential*) and have acquired a reputation for high quality output (Minchin, 1999). As part of state school provision, Tasmania and the Australian Capital Territory provide separate Senior Colleges for students in the last two years of the high school, a form of organisation which may enhance enrichment and specialisation because of the larger number of students enrolled and the expertise of the staff. University High School, Melbourne, accepts an intake of 25 students in Year 7 each year and permits them to extend and accelerate their learning through the grades.

Special classes have also been created at the *primary* school level, mainly for students in Years 5, 6 or 7. New South Wales introduced special classes for gifted students in the final years of the primary school in 1932, a concept which still exists in 1999/2000 despite the vagaries of different political policies. There are

currently 104 such classes, known as Opportunity or OC classes, in 65 primary schools (Bradburn, 1999). Special primary classes are likewise provided in the Northern Territory at Darwin and Alice Springs (Day, 1999).

Full-time special classes for gifted students at the primary level are not immune from controversy, however, as the Western Australian experience has indicated. After the WA Department of Education commenced Full-time Extension Classes for able students in Years 6 and 7 in 1982, there was opposition on the grounds that early specialisation was undesirable, leading to the discontinuation of the units after 1986 and to a concentration on part-time programs and on cluster group provision.

While the above examples may indicate a range of special school/class provisions, the majority of Australian schools do not have special, standardised identification procedures for gifted students and do not provide special classes for them. Most primary schools retain whole-class instruction in comprehensive settings and promote children on a lock-step basis. Many high schools grade students in mathematics and languages, placing the highest performers in selected classes in each grade and leaving the rest of the students ungraded. The debate on the merits of *graded* vs. *ungraded* classes is ongoing.

#### Cluster Groups/Networks

Cluster groups are seen as a specialised and economical way of providing for gifted students at primary and secondary level, allowing a number of schools which are in close geographic proximity to plan and implement joint educational programs for teachers or students. When students are involved, they permit small numbers from two or more schools to combine for enrichment or extension activities on a part-time basis, the schools sharing the costs involved and having access to expertise that each could not provide individually.

During the 1980s they were particularly popular in Victoria and Western Australia although they existed in all Australian states in some form. Since that time their popularity has declined because of the time and organisation involved, the problems of transporting students between schools, and the consequent absence of pupils from regular classes on a continuing basis. Other forms of joint activities and networking have now been developed in their place.

One exception to this decline is found in Western Australia where cluster groups have been perfected and embedded in mainstream provision. Developed from the original pyramid-approach to gifted education, the Primary Extension and Challenge (PEAC) program is a statewide initiative that offers challenging experiences to gifted students in Years 5–7 (ages 10–12) as part of their normal school program. Most children are tested in Year 4 and, if they meet the relevant criteria, are

Table 1. Examples of Programs offered at PEAC Centres in Western Australia.

Statistics	What if . . . ?	Solar energy
Electronics	Aborigines	Man in flight
Japanese culture	Italian	French
Meteorology	Zoology	Theatre
Anthropology	Computers	Propaganda
Magnetism	Astronomy	Chemistry
Extension math	Forestry	Paleontology
Left to write	Polyominoes	Algebra
Aviation	Esperanto	Microscopes
Nordic myths	Poetry	Natural disasters

placed in a pool of students who may attend courses in PEAC centres throughout the state over the next few years. These courses are provided on a wide range of themes which vary from year to year depending on the self-expressed interests of local students. Examples of courses are outlined in Table 1.

PEAC Centres are located throughout Western Australia in both metropolitan areas and country towns. They operate for the entire school year providing withdrawal programs for children who are drawn from surrounding schools and who attend for half a day each week for 6–10 weeks or longer. Programs are designed to provide challenging content and to train research and independent study skills, as well as affording a chance for gifted and talented students to meet and support each other in their interests. Entry to these extension courses has been broadened over time so that children who are not in the selected pool are also permitted to attend individual courses if they demonstrate high ability and interest in a specified area.

PEAC courses have proved popular with students and teachers because of the interest they provide, the motivation they generate, the enrichment and extension they impart, and the positive attitudes to learning which they foster. They have not only won the approbation of parents but have also been accepted by all major political parties in the state. This form of gifted education has now been accepted as normal mainstream provision, Western Australia being the only state to achieve this commendation.

In the north of Australia, three sectors—the NT Department of Education, community groups, and the Northern Territory University—provide and coordinate regular vacation schools for senior secondary students in order to encourage study at post-secondary level and to introduce all ethnic groups to advanced study. At the same time, the *Aboriginal and Islander Tertiary*

*Aspirations Program* (AITAP) is designed to increase the number of Indigenous students who successfully complete the Northern Territory Certificate of Education and proceed to college/university studies (Day, 1999). Both programs assist motivation and broaden the horizons of students.

As part of its *Bright Futures* program, Victoria has emphasised local teacher networks to "assist teachers and parents in Government, Catholic and independent schools to meet gifted students' needs" and has developed clusters of primary and secondary schools "to offer a world class standard in particular curriculum areas such as science, sport, LOTE [languages other than English], visual and performing arts, and information technology" (*Bright Futures*, 1995). It is apparent that the original concept of school clusters has now been broadened, aided by interactive information technology.

Networking assumes a new dimension when schools develop particular expertise and become models for others to emulate. There are eight Focus Schools in Queensland which act as centres for training and research and invite others to visit and observe their approach (Education Queensland, 1999). Networking also forms the basis of the South Australian *Focus School Program* where teams assist local schools and groups of teachers (Minchin, 1999).

#### Special Interest Centres

Special Interest Centres are secondary schools, usually comprehensive in nature and serving all students in the neighbourhood. Additionally, they have a specialised discipline area that attracts highly talented students from a wide geographic area because of the high quality instruction that is available. In South Australia there are currently four Special Interest Secondary Schools which specialise in music, one in languages, one in agriculture, and two in sports (Minchin, 1999).

In the music centres, students follow a normal high school course as well as specialising in the theoretical and performance strands of music. In one school, tuition is available in flute, piccolo, oboe, clarinet, saxophone, bassoon, trumpet, french horn, trombone, tuba, violin, viola, cello, classical guitar, untuned percussion (xylophone, etc.), piano, pipe organ and voice. It is not unusual for students to integrate their studies in the performance arts, and to excel in many aspects of academic and social life. The staff are highly qualified and develop excellence that spreads to other teaching departments.

Influenced to a degree by this South Australian concept, New South Wales created the Newtown High School of the Performing Arts in Sydney, a comprehensive school with specialities in the visual arts, dance, drama, and music. Students who concentrate on dance, for example, must study composition, appreciation and performance, and may select from the following styles: traditional, modern, classical, jazz,

African-derived modern, Aboriginal, ballroom, and Latin and American dance. Other students who do not specialise in the performing arts are still included in a wide array of related activities (set production, audio backup, organisational activities, publicity, design, technology, etc) and benefit from the excellence engendered within the school.

The special interest high schools with the longest history are found in Western Australia where the Department of Education has grafted specialist disciplines onto 11 existing comprehensive schools in the Perth metropolitan area. These schools, some with special programs dating from 1968, provide high level instruction in the areas of art, languages, music, dance and/or theatre arts, and select students on the basis of interview, performance, folio presentation, and standardised testing if appropriate. In general the students who enter the 11 classes each year are expected to work at a sustained pace and to aspire to excellence. The programs are widely acclaimed throughout the state because of their high quality and the outstanding levels of student performance.

More recently, Tasmania has developed four schools with special programs in performing arts, information technology, and off-site studies (Fagg, 1999) while New South Wales has a widely acclaimed Talent Development Project in the arts area which identifies and provides for students with outstanding talents in the field of popular entertainment (Bradburn, 1999).

#### Acceleration

Attitudes to acceleration have softened in Australia over the past decade and there is now less suspicion and a wider acceptance of the practice. In the Northern Territory, for example, the Policy for the Education of Gifted and Talented Students (NT Policy 1992) indicates unequivocally that acceleration can assist some gifted students. In other states such as the Australian Capital Territory (ACT Draft Policy, 1998), it is spelt out in considerable detail and safeguards are outlined. Nonetheless, all states and territories specifically detail it as one strategy, often in concert with others, to provide more adequately for the education of the gifted.

Western Australia was the first to espouse acceleration at system level when it encouraged the ten high schools with special classes for intellectually talented students to accelerate the progress of those whose learning was advanced. The Ministry of Education in New South Wales formally accepted and publicised the benefits of accelerated progression in 1991, issuing a publication entitled *Guidelines for accelerated progression* (Board of Studies, NSW, 1991) to all schools. School principals have the final responsibility for deciding cases of early entry to school and of accelerated progression through the grades.

Subject acceleration is more widespread than total grade skipping, and occurs naturally in vertically

organised classes, in classrooms where teachers encourage children to work at their own pace, or where individualised programs are devised. Despite these changing attitudes, there is still considerable opposition to acceleration in individual schools on the alleged grounds of negative social-emotional outcomes or because of the restrictions imposed by the ubiquitous high school timetable.

In its widest sense, acceleration is multi-faceted as indicated in the Northern Territory Policy. Schools are informed that acceleration may assume many forms but essentially means that a student will complete some or all of his/her formal schooling requirements in a faster time than average peers. Some of the ways in which this can be achieved include:

- early admission to preschool, primary school, junior high school, senior high school;
- curriculum presented above year level;
- students accelerated into an older age group to work in one or more subjects;
- full-time classes of identified gifted students;
- family (vertical) grouping in the secondary school;
- curriculum presented at a faster rate in the mainstream classroom;
- students given credit for successful completion of courses at other institutions (NT Policy, 1992).

Victoria, having already established an acceleration program at University High School, Melbourne, in 1981 decided to create additional *select entry accelerated learning programs* in the mid-1990s, allowing students to complete their six years of secondary schooling in five years. As an extension of this type of acceleration, Victoria allows selected secondary students to study first-year university subjects as part of their Year 12 school program (*Bright Futures*, 1995). A similar scheme operates in other states including New South Wales and the Northern Territory.

Overall, therefore, the practice of acceleration is more widely accepted than in previous years although it is still likely to produce negative emotive responses from those who are not convinced by the overwhelming amount of research findings on the topic or who cling to age groupings that supposedly create homogeneous ability classrooms.

### Enrichment

Enrichment is nominated to be the most widely used strategy across Australia in providing for gifted and talented students. Significantly, it is often referred to by the term *enrichment activities* rather than *enrichment programs*, an indication of the fragmented nature of the approach frequently adopted. In defence of enrichment as a strategy, it is claimed that it may be integrated with regular classroom instruction and that it causes less disruption to the normal school organisation than some other approaches. It is obvious, however, that much

confused thinking exists about the purposes of enrichment and the target group for whom it is intended. Some teachers confine enrichment activities to a small, select group of children who are considered to be gifted in some way, but the majority believe that enrichment is appropriate to the needs of all children and should not be restricted to predetermined groups. It takes time for some teachers to realise that enrichment is a complex concept that may be implemented at different levels and for different purposes.

Queensland has developed a model of curriculum provision "for gifted education and talent identification" that operates at four interrelated levels and incorporates enrichment within a wider framework. While it is applicable to all students in primary or secondary schools, it is "specifically intended for schools to identify and meet the needs of potentially gifted students" (Education Queensland, 1999).

*Strand 1* activities are designed to expand interests and to identify the talents of all children. Such activities include concerts, debating clubs, competitions, sports days, chess clubs, camps, choirs, musicals and art/drama festivals which, while providing cultural enrichment, help to identify students who may benefit from similar activities at a higher level. The teacher observes those who meet the criteria of advanced studies, discusses extension/enrichment possibilities with parents (if children are young or if money is involved), and encourages students to participate in higher level activities. This may include extra-curricular activities such as mini courses (in a sport for example), drama and dance classes, music lessons, a Double Helix Science Club, Aboriginal art classes, a Vietnamese Saturday School, or a writers' circle.

*Strand 2* introduces or extends higher level thinking activities, thereby allowing students to participate in school and regional events or competitions. Its purpose is to identify students, including those who under-achieve, to participate in teams and withdrawal programs and develop self confidence and self understanding. Identification opportunities are provided through Maths Challenge Days, art festivals, leadership courses, mini Thinkfests and mini-Tournament of *Minds*. The criteria to enter various programs are specified and students are tutored in the skills required. A Maths Challenge, for example, is based on problem solving skills, motivation and analytical processes and, hence, these are developed so that particular students may enjoy and excel in the Challenge. *Tournament of Minds* requires creativity, leadership, problem solving ability, communication and interpersonal skills and these are taught and stressed for those who desire to participate in the Tournament. Other school and community-based activities are similarly analysed in order to extrapolate the requisite skills and strategies which are then developed over time. As a result of the teacher's observations, students may be offered places in pull-out programs such as leadership courses,

writers' camps, philosophy forums, industry placements, Thinkfest programs, *Tournament of Minds*, or Excellence Expos.

*Strand 3*, termed *implementing gifted education*, seeks to identify students who need differentiation, provide an appropriate curriculum for them, and empower them to be autonomous learners. Based partly on Maker's four basic modifications (content, process, product, environment) and on Braggett's seven categories of differentiation (speed, cognitive processes, enrichment/extension, personal experience/autonomy, multiple intelligences, deductive thinking, social change), the Queensland model encourages students to be involved in a differentiated curriculum that permits and develops independent learning, research and reporting skills, problem finding and solving ability, high level critical and creative thinking skills (eg. analysis, synthesis and evaluation), communication skills, and task commitment. Teachers are required to identify their learning objectives, pretest students for prior mastery, and eliminate unnecessary teaching. The end product allows students to be involved in negotiated activities, extension programs or independent study.

*Strand 4* is designed to "identify students who need negotiated, differentiated curriculum (an individualised work program) and to facilitate independent learning." Influenced by a number of researchers including Renzulli, the negotiated curriculum may entail acceleration/compaction, mentor programs, contracts, dual enrolments and extension programs. Individualised Education Plans are integral to this level of the program. The model makes it clear, however, that students do not pass through these four strands in a linear fashion but that they are simply guides for identification and curriculum provision. Students who perform at an advanced level in Strand 1, for example, may proceed directly to Strand 4 if they possess the requisite skills and strategies.

While there are many other equally useful models available to teachers, the Queensland model illustrates a trend in many Australian schools whereby increasing numbers of teachers are seeking to base their enrichment programs—indeed their entire teaching—on a sound theoretical basis. Bloom's *Taxonomy* was one of the first models to achieve widespread appeal, particularly at the primary school level. Hence, while there is legitimate criticism that some enrichment activities are low level and lack educational rigour, it is encouraging to see a widening awareness of the concept of enrichment and a willingness to combine it with a differentiated and negotiated curriculum. In addition to the Queensland model, this move has been assisted by the Western Australian TAGS Kits for primary (Education Department of WA, 1995) and secondary schools (Education Department of WA, 1996); a range of publications by the South Australian, ACT, and Victorian Departments/Ministries of Education; and recent

Australian educational publications that emphasise the need for differentiation.

#### Supplementary Programs

In addition to class-based programs, there are other initiatives which influence gifted education and frequently involve wider community input. First, there are numerous mentor programs for individual students who exhibit outstanding performance or potential. These exist in most Australian states and territories, sometimes coordinated by the State Department of Education, sometimes by district or school authorities, and occasionally by a parent association. In New South Wales, for example, the mentor program is designed for students 10 years of age and over, and operates in 26 districts across the state.

Second, the rapidly increasing use of information technology is having a decided impact on the delivery of services for gifted and talented education. Not only is this opening opportunities for students who live in more remote areas of the country but it is also providing an unprecedented array of programs for city and rural areas alike. In Victoria the Department of Education and the University of Melbourne combine to provide mentor programs for secondary school students via e-mail and other interactive technology between face-to-face sessions, while programs such as *As the Crow Flies* and *Horizons Programs* permit students to use the Internet and other technology in high quality enrichment and extension programs. Interactive television also permits teachers to participate in professional development courses despite the separation of distance.

Third, there is enthusiastic support for camps that provide enrichment/extension in such talent areas as creative writing, drama, art, music, maths, science, languages, computers and gymnastics. In most states the camps are organised by individual schools or on a district basis but the Northern Territory Department of Education arranges vacation schools and provides funds for students to attend from all over the Territory.

Fourth, there are numerous national challenges and competitions that are open to students and which promote excellence. The *Tournament of Minds* has achieved a high degree of popularity since 1987. An extension of the American *Odyssey of Minds*, the Tournament is conducted in divisions that allow primary and secondary schools to participate, each school presenting a team that competes against others in problem solving situations. It is well known in every Australian state and territory and involves students from state, Catholic and independent schools. Another venture, the *Future Problem Solving Program*, is a year-long program that promotes critical, creative and futuristic thinking among students at all levels of schooling and challenges them to apply advanced thinking strategies to significant issues. Literacy, mathematics, science, and other reputable competitions

are conducted by associations, banks, universities, and major firms.

Fifth, the education of gifted and talented students often incorporates other bodies, associations, and institutions as well as schools. Business houses are involved in some programs, while museums, art schools, zoological gardens, botanical gardens, Aboriginal Centres, industrial complexes, and other specialist groups contribute across Australia. Some universities and colleges have always contributed, both to individual programs and to the professional development of teachers.

#### Other Organisations

There are two other groups which have a major input into gifted education and provide important services to the community. The first group comprises the State Associations which were established during the late 1970s when the gifted movement was in its infancy. At that time the assistance of parents and community members was crucial because it broadened the base of the agitation for change and pressured governments to respond. Parents and professional educators banded together and established state associations, all of which have continued to have a significant input into the gifted cause. In general the associations operate in a professional manner and supply a valuable service for parents and teachers alike. This is done through advisory services when parents/teachers write or telephone for assistance, through publications that explain giftedness and gifted education, through programs for children (usually at weekends or in vacation time), and through conferences and regular meetings that involve local, national and international speakers. Most publish a journal that is distributed to members on a regular basis, while in some states there is a close working relationship between the Association, the Department or Ministry of Education, schools, universities and/or teacher organisations.

The Australian Association for the Education of the Gifted and Talented (AAEGT) was formed in 1985 and has assisted in developing awareness of giftedness across the country. It organises conferences and workshops, publishes the *Australasian Journal of Gifted Education*, conducts national competitions for students, acts as a lobby group, and liaises with all state associations. It contributes to National Conferences which are hosted in the various states every two years and, in 1989, organised the *8th World Conference on the Gifted and Talented* in Sydney.

The second major group includes academics who work in universities and colleges across Australia. They have been, and continue to be, at the forefront of the movement in many states and at the national level, providing strong support in teaching, writing, and researching about giftedness. In contrast to the early 1980s, it is now possible to specialise in gifted education at undergraduate and graduate levels in a

number of universities. Academics also play an important role at the inservice level where they provide professional development programs. The publication, *TALENT-ED*, edited by Bailey at the University of New England, provides very useful material for teachers.

Overall, therefore, one may discern seven major types of provision for gifted and talented students in Australia, ranging from state-wide programs with Departmental imprimatur to in-school enrichment programs that reflect local-school initiatives. While the range of these programs is considerable, it must be stressed that gifted initiatives are not uniform across the states and territories, that state political priorities are usually reflected in the educational policies espoused, and that egalitarian philosophies are strong among some teachers and community groups. Nevertheless, the advances over the past decade have been numerous and reflect an ever-increasing awareness of the needs of the gifted.

#### New Zealand

The last decade has seen a dramatic shift in the perception of giftedness and in provisions for the gifted in New Zealand. The educational reform process, begun in 1989, has contributed to these changes, and has been more positive than negative. In an earlier national survey into the restructuring process, there was evidence of a growth in programs for the gifted (Keown, McGee & Oliver, 1992), while the growth of 'special' programs across the country was greatest for Maori children and for the gifted.

Studies by Moltzen (1992) and Moltzen and Mitchell (1992) sought to understand how the process of change impacted upon the gifted. The reforms had their origins in the report of the Picot Taskforce (Taskforce to Review Education Administration, 1988), later interpreted in a government white paper, *Tomorrow's Schools* (Lange, 1988), and finally expressed in the Education Act 1989 and its amendment. While none of these documents made reference to the gifted, there were aspects of the reforms that were to affect such students. Devolution of responsibility to local schools carried with it the possibility of change which was translated into positive educational initiatives. For example, while little direction had been previously provided by central or regional bodies, many principals in Moltzen's (1992) study felt an increased responsibility to provide for their gifted students. In this new era, schools are encouraged to design/develop their own programs in consultation with their communities, and they have the financial autonomy and flexibility to appoint staff and allocate resources to this end. It quickly became evident that schools used this new-found freedom to develop programs for their gifted (Moltzen, 1992). Moreover, the enhanced role of parents in school governance resulted in a higher priority for gifted programs than in previous years (Moltzen, 1992; Moltzen & Mitchell, 1992) as it was

found that many parent trustees raised concerns about the gifted and frequently expressed dissatisfaction with their school's provisions for this group.

An aim of the reforms was to create an educational environment which encouraged parents to select schools that best suited the needs of their children: it is believed that competition improves the quality of school education, that 'good' schools experience growth, and that 'poor' schools suffer a loss of enrolments, forcing them to address their inadequacies. In this environment, school image is of primary concern, and the gifted become a 'marketable commodity' (Moltzen, 1992). In Moltzen's study (1992), programs for the gifted were seen as a positive 'shop window' for the school, while some principals unabashedly admitted that promoting programs for the gifted was sound 'marketplace practice'.

Ten years after the introduction of the reforms, these trends have continued and many gifted students have gained from the increased attention. Nevertheless, the increased provision has not been universal. Without specific 'national' direction, any initiatives are dependent upon local interest: if a school does not identify the gifted as a priority, little is likely to occur. While some schools are doing well, others are achieving very poorly. Moreover, it is apparent that schools in higher socioeconomic areas have had a monopoly on developments for the gifted because the parents in these communities are more likely to press the cause with the school and its trustees.

There also appears to have been some change in the type of provision for these students. The diversity of programs is definitely greater than in previous years, the result in part of schools seeking to offer something in advance of their 'competitors'. New Zealand educators retain an affinity for more inclusive approaches to giftedness but seem less self-conscious about implementing strategies that may draw attention to these students.

#### The Regular Classroom

Provisions for the gifted beyond the regular classroom have traditionally been very limited in New Zealand, egalitarian attitudes constraining any initiatives to place the gifted child in a setting other than with his/her peers of the same age and grade. Within the regular classroom the gifted are usually offered a program of enrichment, which is frequently criticised for being little more than 'busy work' and offering more of the same (Townsend, 1996). The extent to which their special abilities are identified and nurtured is almost entirely dependent on the knowledge and skill of the regular classroom teacher. However, what could previously be viewed as a 'default' provision, is increasingly being selected as a preferred approach. Many schools, in reviewing their programs, have examined a range of possible approaches and have decided that the regular classroom is the most appro-

priate context in which to place their efforts (Moltzen, 1998), a viable option within the New Zealand Curriculum Framework. Frequently this approach is supplemented with other programs but the major provision is based in the regular classroom and delivered by the regular class teacher. Most schools which choose this preferred approach recognise the importance of providing a comprehensive professional development program to assist teachers with the knowledge and skill to undertake the role.

#### Pullout Programs

Pullout programs continue to be the most popular 'supplementary' provision for the gifted in primary schools, a more conservative approach which finds favour in New Zealand because it is less likely to attract charges of elitism while still offering the gifted something in the way of a dedicated and special program (Moltzen, 1998). It usually sees gifted students withdrawn from their regular classes for a morning or afternoon (sometimes an entire day) for a period of about six weeks, to work together on a specialised area of study. They are usually drawn from classes at different levels, and thus the age range of the group may cover three or four years. As the program focus varies greatly, it is sometimes related directly to curriculum areas, but more often it seeks to allow students of like mind to work on topics outside the regular classroom program. In the country's egalitarian tradition, a broad range of topics is usually provided so that as many children as possible are included in such enrichment programs.

#### Acceleration

Reid (1991) referred to acceleration as the 'Cinderella' provision for gifted students in New Zealand. When 152 primary school teachers and 140 trainee teachers in their final year of training were surveyed, it was found that both groups held relatively positive views about acceleration (i.e. grade-skipping) but that approximately 50% had reservations about the social and emotional effects associated with the practice. In an earlier study, McDonald (1988) reported that "virtually no children are accelerated in New Zealand schools" (p. 2), despite legislative provision for flexible promotion, and revealed that Maori children (particularly boys) were less likely to be promoted out of the junior classes. Girls, on the other hand, were more likely to be promoted at an earlier age than boys, regardless of their demonstrated level of academic achievement. Although there is some anecdotal evidence that schools are now somewhat more likely to accept acceleration, there is still a belief that it will do more harm than good. Moltzen (1995) suggested that the positive findings from numerous research studies on acceleration were largely unknown.

Curriculum acceleration is more widely practised. The National Curriculum is designed to allow vertical

movement, and teachers are encouraged to place children at levels commensurate with their ability. This may occur in the regular primary classroom, if a teacher allows children to work at a range of levels, or by accelerating children to a higher level in specific subjects, notably in reading and language. Some primary schools make provision for gifted children to study a subject at a neighbouring intermediate- or high school. While still uncommon, a few secondary schools make provision for their most able students to study university courses. Curriculum acceleration at the secondary level is most likely to occur in mathematics but the practice also occurs in science and music.

#### Separate Schools/Classes

The only New Zealand school specifically established to cater for gifted students is the Thomas Kennedy Academy at Raumati South, just north of Wellington. It currently enrolls 62 children, ranging in age from four to 13 years, and caters for children with special abilities in a spectrum of areas, not confining itself to exceptional intellectual and academic ability.

In the 10 years since the latest educational reforms, there has been a growth in the number of separate full time classes for gifted students, most evident in intermediate (middle) schools and high schools. This organisational option is easier to implement in an intermediate school, where students spend more time with a 'home class' teacher. In high schools it is more difficult, requiring some to limit the subject choices available to gifted classes to maximise the time that students spend together as a group.

Nawton Primary School in Hamilton is a rare example of a primary school that provides for gifted students in two separate classes—one for five to seven year olds and the other for children eight to 11. Situated in a low socioeconomic area, the school reports that, because teachers were required to meet the diverse range of special needs in their classrooms, the most able students frequently missed out as their needs were perceived as less urgent and less demanding (Bendikson, 1997). The school community debated the issue and agreed to educate the gifted in separate classes. Significantly, the principal believed she would not have considered this option in a higher socioeconomic area, where—with fewer students with special needs—the regular classroom teacher is more capable of providing for the gifted.

#### Cluster Grouping

Bendikson (1997) found that the most common method of assigning students to particular teachers is the pepper pot approach, in which children with common characteristics are spread across a number of classes to ensure that no teacher is assigned a disproportionate number of children of a particular character. In this way, the children who manifest challenging behaviour, have special needs, exhibit learning disabilities or

display giftedness are divided on an 'equitable' basis among the classes. While there are occasional attempts to place children with teachers who can meet their particular needs, there is an overriding concern that no one teacher is overburdened or overblessed. Some schools have concluded that this is not the best use of resources and 'cluster' gifted children in a class with an empathetic teacher. Ilam Primary School in Christchurch adopted this approach some years ago and believes it is a most effective way to cater for these students.

#### New Zealand Correspondence School

The Correspondence School, established in 1922, provides for students who cannot attend school or pre-school, because of remoteness or sickness or because they live overseas. Nevertheless, this School is increasingly providing for gifted students who receive the majority of their education at their local school, while the Correspondence School provides tuition in subjects not locally available. In 1999 the Correspondence School enrolled 239 gifted students in its courses; 198 primary and 41 secondary, with eligibility being limited to the top 5% of the age group in general ability. The verification process was not particularly rigorous, however, and there are a number of present students who do not meet this requirement. Enrolments are highest in mathematics and foreign languages.

#### Other Groups

The country's first education centre devoted specifically to gifted education was opened in 1995. Named after a distinguished New Zealand scholar, the George Parkyn Centre for Gifted Education was established to meet a significant gap in official education services. By 1999 the centre had developed a wide range of activities, including the delivery of professional development workshops throughout New Zealand for parents of gifted children and for schools. It also supports research projects, produces resources, and lobbies for improved provisions for gifted children.

The New Zealand Association for Gifted Children (NZAGC), formed in 1975, continues to play a very important role in supporting parents, children and professionals. With 400 members and six branches, the NZAGC supports parents and teachers through meetings, seminars and publications, and provides children with camps, courses, holiday programs and opportunities to mix socially. The National Council of NZAGC organises conferences, provides resource material/library services, raises sponsorship, and advocates and lobbies on behalf of gifted children. NZAGC publishes *Tall Poppies*, a magazine aimed primarily at parents and teachers, and *APEX: The New Zealand Journal of Gifted Education*, a peer-reviewed academic journal designed to provide a forum for the dissemination of research.

The institutions involved in teacher education in New Zealand generally devote a minimal amount of time to the needs of the gifted (Taylor, 1995). Taylor's study found that, where giftedness was included, it was frequently an optional course or a small module within a compulsory course on special education. It would not appear that the time has increased since 1995 given the fact that there has been a significant 'reduction' in the period of time now required to complete a teaching degree. On the other hand, Christchurch College of Education will offer a Masters level course in the education of gifted children from 2000, while Massey University and the University of Waikato continue to be the tertiary sector leaders in this field. Both universities offer undergraduate and graduate courses in the education of the gifted. The Flinders University of South Australia's *Certificate in Gifted Education* is offered in association with the University of Waikato, is co-taught by staff from both institutions and is the only tertiary qualification in gifted education available in New Zealand. Riley, the coordinator of gifted courses at Massey University, and Moltzen at the University of Waikato both report a recent growth in course enrolments, particularly among practising teachers at graduate level.

The Education Review Office (ERO) is the government department that reports on the quality of education in all New Zealand schools and early childhood centres. In fulfilling this function, its officers inspect and evaluate the quality of teaching and student learning and they consistently highlight issues associated with the education of gifted students (Moltzen, 1999). In 1998 the office produced a handbook entitled *Working with students with special abilities* (Education Review Office, 1998) and, while some of the perspectives attracted criticism, the publication reflected the agency's commitment to improving the quality of education for these students (Moltzen, 1999). The contribution ERO has made in raising the awareness of teachers and principals to the needs of the gifted has been significant.

## Research

### Australia

Research into giftedness in Australia falls into three distinct periods. Up to 1984, much of the research writing was descriptive in character, often reflecting a curriculum concern or reiterating equally descriptive overseas publications (Braggett, 1986). Giftedness was seen as a relatively static concept and identification was a major issue for academic discussion. In the second period from 1985 to the beginning of the 1990s, research explored the multidimensional quality of giftedness and began to highlight the need to develop talent through well delineated programs. Attitudes to giftedness were canvassed, surveys were conducted (Braggett, 1985), 'disadvantaged' groups were tar-

geted, and research funds were related to *Projects of National Significance*. Graduate programs in gifted education became increasingly available at some Australian universities and graduate research began to develop. The third stage, embracing the 1990s and spilling into the new millennium, has witnessed the growth of qualitative and quantitative research, characterised by academic rigour and often involving ongoing longitudinal projects. While some of this has been university-based, much has been in concert with Ministries of Education, school districts, and educational institutions. Graduate Schools of Education have seen a marked increase in the number of graduate students who wish to research the area of giftedness and talent.

A number of themes have assumed increasing importance. Aspects of school organisation have included student acceleration in mixed ability classes and the effects of acceleration on vocational and social outcomes; special class provision and special schools (O'Brien & Vialle, 1998; Geake, 1999; Gross, 1999; Hoekman, 1999; Wood, 1999); the effectiveness of school mentoring programs; vertical timetabling in schools; ability grouping (Geake, 1999); and the ability of the middle school to provide for the needs of gifted students (Braggett, 1997; Braggett, Day & Morris, 1999). Creativity in its various manifestations has been researched by McCann (1999) and Botticchio (Vialle, 1999) while thinking skills, metacognition and multiple intelligences have attracted continuing attention (McGrath, 1998; Chan, 1999; Jewell, 1999a; Vialle, 1999). Geake & O'Boyle (1999) have extended these studies into the brain functioning and neural organisation of highly gifted mathematicians while musical ability has also been researched at different centres (Geake, 1999; Hoekman, 1999). Gender-related issues have been explored in depth (Kerr & Kupius, 1998; Landvogt, Leder & Forgasz, 1998; Lysaght & Vialle, 1998; Flood, 1999) while the attitudes and influence of parents on gifted children continue to attract attention (Knight & Bailey, 1997; Taplin & White, 1998). The socialisation of gifted young children has been studied by Geake (1999) and Porter (1999) while their thinking strategies have been explored by Braggett, Kay & Lowrie (1998). Related research themes include teacher attitudes to giftedness (Pohl, 1998; Smith & Chan, 1998), the education of Indigenous students (Harslett, 1998), gifted disabled students, intervention programs, curriculum innovations, and underachieving students.

While cognitive aspects of development continue to attract the attention of researchers, affective outcomes form an increasing focus where the effects of school organisation, curriculum provision, and teacher approach are viewed in relation to self-confidence and self esteem (Gross, 1999; Marsh & Craven, 1998; Smee, 1999), to motivation (Chan, 1999; Flood, 1999; Gross, 1999; Hoekman, 1999; Street, 1999), and to

learning styles (Hall, 1999). Leadership forms another emerging theme (Jewell, 1999b; Webster, 1999). Much of this research is within the broader parameters of socio-affective development of gifted students, a theme increasingly pursued by Gross (1999) at the Geric Centre at the University of New South Wales. Other universities actively involved in ongoing research include Wollongong University, Charles Sturt University, the Gifted Development and Education Unit at the University of Melbourne, Flinders University, and the University of New England. Additional research is pursued in other universities, in State Departments/Ministries and in individual schools.

#### *New Zealand*

There has been a steady increase in New Zealand-based research in the area of giftedness in recent years, the majority undertaken by the growing number of graduate students, but led by a small group of academics. The publication of *Gifted and Talented: New Zealand Perspectives* (McAlpine & Moltzen, 1996), the first New Zealand text in the field, brought together the work of most of these researchers. One of the more significant investigations reported in this text was that of Bevan-Brown (1996) who focused on special abilities from a Maori perspective, the first comprehensive study to do so. Other researchers include Holton (talented mathematical students); McAlpine (identification of gifted students, and creativity); Moltzen (the life stories of gifted adults); Rawlinson (self concept, self efficacy and enrichment); Reid (program evaluation for gifted students); Riley (computers with gifted students); and Townsend (teachers' perceptions of acceleration and enrichment).

In 1987 Freeman established the journal *APEX* for the purpose of publishing articles about gifted children and their education. In 1993 the New Zealand Association of Gifted Children purchased the journal and in 1997 it became the peer-reviewed *APEX: The New Zealand Journal of Gifted Education*, providing a forum for the dissemination of articles dealing with practice, policies and research in gifted education.

Since its first publication, the *Scale for Rating Behavioral Characteristics of Superior Students* (SRBCSS) (Renzulli & Hartman, 1971) has been employed by many New Zealand teachers despite shortcomings in the New Zealand context. Accordingly, a modified instrument, the *Teacher Observation Scales for Identifying Children with Special Abilities*, was developed, a New Zealand equivalent to the original scale (McAlpine & Reid, 1996). These scales are the outcome of a comprehensive program of research and trialling, and have been well received by teachers.

At the same time, there has been a steady increase in the number of 'gifted' conferences and seminars, often involving high profile speakers from overseas, but

simultaneously providing a forum for local researchers to share their findings.

#### **Future Issues**

It is now 25 years since the so-called gifted movement developed in Australia and New Zealand, leading to an increased awareness of the needs of gifted students and a demand for schools to respond with more appropriate provisions. During that time, there have been marked advances as curriculum developers have sought to introduce more flexible approaches and to depart from grade-related content. It is now more widely accepted that children should move at a pace commensurate with their abilities, be enriched in their daily education, be extended when required, and—in less usual circumstances—be accelerated by year or content. While these trends are obvious in both countries, they are not uniformly observed and there are many conservative elements which continue to advocate egalitarian policies.

There are three pressing issues that need to be addressed if sustained progress is to be made. First, a prolonged public education campaign is required to convince teachers, parents and legislators that the manifestation of giftedness is usually dependent on the home, the school and the community, and that parents and teachers have a significant role to play in the development of talent over time. There is still an acceptance by many that giftedness/talent is fixed by inheritance and that it will materialise in spite of the environment: such people do not see the necessity for high quality programs and appropriate provision. They do not realise the importance of motivation, of self-esteem, of a sustaining mentor, and of sympathetic teachers who nurture giftedness, differentiate the curriculum, and develop children's skills and strategies to the highest level. If this message could be accepted by the community, it would provoke a revolution in education.

Second, when gifted education is envisaged as an appendage to mainstream provision, it is placed in a precarious position when governments change, when budgets are constricted, or when rationalisation is implemented. The education of gifted children must be seen within a *total school approach* in which all children's abilities are catered for and where individual differences are respected. The education of gifted and talented students is a mainstream concern, a part of everyday school life. Moreover, there is no one panacea for all gifted students, just as there is no one approach to students with learning difficulties. The education of the gifted requires the entire staff to be involved, the curriculum to be scrutinised and differentiated when required, and the welfare of all students to be paramount. There has been so much debate on organisational matters such as streaming, acceleration and extension that educators have sometimes forgotten

the central concern of the school—appropriate education for all students.

Third, the situation in Australia and New Zealand demands that considerable attention be focused on regular classroom teachers and their ability to cope with an extended range of abilities in the classroom. While it might be desirable to create special schools and classes, to involve students in pullout programs, and have access to specialist teachers and resources, the reality is different. Most schools will continue to rely on the efforts of dedicated classroom teachers who will do the best they can in the limited hours that are available and with the limited resources that exist. It is encouraging that so much has been achieved over the past 25 years and that teachers are increasingly aware of the need to change. They need to be further supported and encouraged through professional development programs that cater for their needs.

In summary, therefore, Australia and New Zealand have witnessed positive changes over the last quarter of the century and the cause of gifted students has been significantly advanced. As the two countries enter the 21st century, they can look forward with a degree of optimism to an educational future that is challenging, yet most promising.

# The Status of Gifted Child Education in Africa

Cedric A. Taylor<sup>1</sup> and Shirley J. Kokot<sup>2</sup>

## Introduction

Educational developments in Africa cannot be understood without a knowledge of traditional African culture and of political developments in sub-Saharan Africa during and after colonial rule. Therefore a brief historical background is given of political developments in that region. A number of issues which determine educational planning and priorities and also have implications for decisions regarding gifted education emanate from that complex set of historical, political and cultural factors. Those issues concern the historical background of unequal and segregated education, African culture, different and elitist conceptions of gifted education, different interpretations of equal educational rights, the goal of universal primary education, the priority of majority needs, economic conditions, and the marginalization of education. A brief historical overview is given of gifted education in sub-Saharan Africa that illustrates the inequalities inherited from a combination of First World and Third World education systems on the same continent. The same pattern is discernible in the search for an identification procedure that would apply within diverse cultural, ethnic and national groups. Future development of gifted education in African countries is seen as dependent on a restructuring of gifted education in the context of national developmental needs. Some aspects that need to be researched in this respect are outlined.

## A Historical Perspective

### *Brief Historical Background of Political Developments in Africa*

The colonial past of Africa and events subsequent to the attainment of independence by sub-Saharan African countries need to be taken into account to understand political, social and economic issues that may directly

influence policy decisions regarding formal provision for gifted children in the education system. A brief overview is given of the situation immediately preceding and after the granting of independence to African countries by colonial powers.

During the pre-independence period most colonial powers unscrupulously exploited the human and natural resources of sub-Saharan African countries for their own purposes. The political, economic, social and educational development of these countries and their peoples were considered of lesser or no concern. In some cases a minority of African elites were educated in Western education systems and allowed limited participation in government. Missionary schools provided basic training in reading and writing to a small percentage of the masses.

In the 1960s the winds of change began to sweep over the African continent, heralding the end of colonial rule and the dawn of uhuru ('freedom'). In a relatively short period of time, however, independence led to authoritarian regimes of one kind or another. In most cases, the demise of constitutional democracy began with a movement to one-party and ultimately one-man rule. This was due in some countries to the electoral supremacy of the ruling party and the high degree of elite cohesiveness before independence. In others, one-party regimes were established with extensive coercion and personalization of power (Diamond, 1988). A period of prolonged instability followed, characterized by successive power struggles, coups and dictatorships which in many cases led to civil war, and the destruction of the economy and poverty. An important contributing factor to this state of affairs may have been the fact that at independence most new African states were left in conditions of more or less acute economic dependence and not prepared politically and administratively for independence by the colonial powers. This may have led to a heightened sense of vulnerability felt by African leaders for their young countries which served to justify a concentration of power as a means of asserting control (Diamond, 1988).

In recent times some African countries have started to rebuild their economies and a move has become

E-mail: kokotsj@alpha.unisa.ac.za

apparent towards a more democratic form of government. This observation is supported by the following events:

- In 1981 the African Charter on Human and Peoples' Rights was adopted in Nairobi, Kenya by the Organization of African Unity (Shiman, 1988).
- Two sub-Saharan African states, Senegal and Ivory Coast, participated in the Second Strasbourg Conference on Parliamentary democracy in 1987 (Council of Europe, 1987).
- Botswana continues to be one of the best examples of multi-party democracy in Africa. Moreover, in a decade and half, Botswana moved from being one of the poorest countries in Africa to one of the richest, with per capita GNP increasing from \$100 to over \$900 (Holm, 1988, p. 197). Heavy and well-distributed investments were made, amongst others, in education (Diamond, 1988).
- Namibia has established a democracy and multi-party elections have taken place in Zambia and more recently in Nigeria; a democracy persisted for a period of time in Zimbabwe.
- A Pan-African Conference on Democracy, organized by the Minister of State of Senegal in Dakar in 1992, was attended by 47 states.
- South Africa held its first democratic election in 1994.

Countries in Africa are entering a new phase of development, learning what democracy means in practice, for government and society. Democracy, however, means different things to different people. The form of democracy that will develop in the African context and its implications for education remains to be seen.

Events in South Africa followed a different course. Colonies formerly under British rule and granted self-government in 1905, formed the Union of South Africa in 1910 as an independent country. A multi-party democratic form of government was established with qualified franchise for coloureds, Indians and blacks that in effect limited representation in parliament to whites. The Nationalist party which came into power in 1948 progressively consolidated social, residential, cultural, economic and political apartheid constitutionally over the next four decades. While separate Houses of Parliament were created for coloureds and Indians in 1984, the blacks who form the majority of the population had neither vote nor representation in Parliament. The speech by President F. W. de Klerk on February 2, 1990, however, heralded the beginning of the end of apartheid. On June 17, 1991, the legal foundation of the apartheid system was eliminated when Parliament scrapped the law classifying South Africans by race from birth. A new constitution has been drawn up that is based on human rights and democratic principles.

### Issues Impacting on the Provision of Education for the Gifted

Certain issues that emanate from the historical and cultural context of a country may directly influence policy decisions regarding gifted education. Issues that are relevant in the African context are discussed below.

#### *Pre- and Post-Apartheid Educational History in Southern Africa*

Little is known about traditional education in pre-colonial southern Africa. Ceremonial forms may still be seen in initiation (amakweta) ceremonies, but the social meaning has often changed. For example, such ceremonies had increasingly sought to make social distinctions between the 'red' (traditional) and 'school' (Christian modernizing) people during the nineteenth century. While traditionalists looked to the practices of the rural past for the methods of shaping educational meaning in a 'tribal' context, there was a gradual increase in the number of 'school' people attending a network of Christian mission schools throughout the region. These schools were seen as the gateway to 'Western civilization' and the formal labor market (Middelton, 1997, p. 5). Apart from 'flagship' schools that were run by missionary institutions in certain towns and cities, a vast network of small rural schools was established by the mid-twentieth century. Among these were a range of educational initiatives by African Independent Churches, controlled by black Africans. Even before the advent of an apartheid regime under the National party in 1948, a colour bar existed that protected white workers from black competition. Yet for the small number of blacks—an emergent elite—who managed to survive to high school in the missionary run 'flagship' schools, the quality of the education received was on a par with the education of the Europeans. It was from this group that the African nationalist leadership was drawn (Middelton, 1997).

In 1948 the Nationalist Party came into power with fundamental implications for the sphere of education: time-honoured segregationist policies were honed into the racist dogma of apartheid (Middelton, 1997). The notorious Eiselen Report on Native Education (1951) set the tone by arguing that each cultural group should have its 'own education' suitable to its 'own needs' and focused on the development of its 'own people in their own areas'. Subsequently, all education other than that intended for white children was removed from the control of education departments in the various provinces and placed in the hands of state departments concerned with the affairs of the various racial groups as defined by apartheid. The missionaries were forced to hand their schools over to the state.

Gradually, education was increasingly fragmented, first into the Bantu (African), Coloured and Indian categories; then, the control of African education was

divided between no less than ten 'homeland' administrations and the Department of Bantu Education which served the African population outside of the homelands.

While these developments were taking place in South Africa, the neighbouring anglophone states of southern and central Africa were moving toward independence an establishing themselves as part of the African family of nations in the era of Uhuru (English: freedom). In the first rush of independence, there was great emphasis on education for development, and many new schools and universities were opened in all areas (Middelton, 1997). The major difference between African education in these areas and in South Africa is that in the former there was an unbroken tradition of church-state cooperation, which enabled the quality and the quantity of education to develop apace despite declining resources (Middelton, 1997). The only exception was Rhodesia (now Zimbabwe), where white privilege played a significant role in the shaping of the politics of education.

The 1980s are considered as the era of reformism in South African education and in 1981 the report of the (De Lange) Committee of Investigation into Education, recommended "equal opportunities for education, including equal standards in education, for every inhabitant, irrespective of race, colour, creed or sex." Yet the committee stopped short of recommending a non-racial system. Many of the reforms recommended by this report were implemented during the 1980s and they also formed the core of the Department of National Education's Educational Renewal Strategy, published in 1992, which was to be the blueprint for the National party's educational policy for the post-apartheid era (Middelton, 1997).

With the advent of the new, black, government in 1994, education has been high on the list of priority matters to be rapidly addressed in South Africa's emerging democracy. The issues surrounding the drive towards educational reform has been a dominant and intense subject of debate even before the current political transition. The debate, while focusing on the needs of the historically disadvantaged population groups, strives for a solution that should, according to Hartshorn (1992), provide all children with relevant and equal education of an acceptable standard. The merging of segregated Third World and First World schools into a unitary system of education has not been without many problems and accompanying tension. A major problem has been a lack of finance to redress past inequalities without lowering the standard of education in previously advantaged schools. Government introduced 'outcomes-based education' (OBE) in an attempt to transform the system, as well as the policy of inclusion in order to answer to the human rights issues of equality for all learners. Their answer to the lack of finances has been to increase the learner-teacher ratio in all classrooms to 35-1. Teachers in

schools with previously low learner-teacher ratios have been forced to either relocate to other schools or have lost their posts. In many cases, teachers are unwilling to move to rural areas where school buildings are inadequate in terms of facilities and resources and the staffing of schools remains a problem. Many classes in rural areas may number upward of 60 learners to a single teacher, while the previously white schools are struggling to accommodate as many as 40 children in classrooms designed for 25. Many schools in poorer provinces, such as the Northwest Province lack textbooks and even leadership. Poor matriculation results at the end of 1998 have been blamed on the fact that hundreds of schools in this province lack a principal and over 1000 schools lack a deputy principal (SABC-TV news broadcast, April 10, 1999).

In the light of this, making special provision for a relatively small group of gifted pupils is seen as a waste of resources and those built up over years in this respect have and are being abandoned in order to make provision for needs considered as more pressing. Thus, gifted education is rejected by many because it is considered to be a part of the education system of an oppressive regime. Others consider it to be an expensive luxury. However, it is also important to understand the culture of black Africans in order to fully understand issues regarding gifted education.

#### *The Culture of Black Africans*

In the aftermath of independence when African countries were struggling to escape from their colonial past and re-establish a traditional African way of life, leading thinkers such as Kwame Nkrumah, Julius Nyerere, Leopold Senghor, Koli Busia and Kenneth Kaunda responded with a new philosophy: African socialism. African socialism, according to du Plessis (1992, p. 9), professes to make sense of the traditional (African) way of life in a modern world. Its perception of society is said to be rooted in the idea of *ujamaa* (English: familyhood, togetherness) and both its foundation and objective is the extended family. Within this context the state is considered to be but an extended family requiring an involved personal loyalty from its citizens. A multi-party system is seen as inherently divisive. Moreover, *ujamaa* represents a call for communal co-responsibility towards the upliftment of those in society who, in some or other respect, have remained behind. African society's values are directed towards the maintenance of cohesiveness and solidarity, and one of the strongest social control agencies is the extended family, imbued with the principle of collective responsibility. In this context children who have fallen behind or have been disadvantaged will receive priority educational treatment before those who are managing well, which in many cases may be perceived to be the gifted.

African culture values and nurtures the attitude and behavior of identifying with others, understanding and

responding to another person's needs and sharing emotions. Archbishop Desmond Tutu (1991) has referred to "... our sense of ubuntu—our humaneness, caring, hospitality, our sense of connectedness, our sense that my humanity is bound up in your humanity." Traditionally, the African's concept of who he/she is can be summed up in the words: "I am, because we are, and because we are, therefore I am" (Mbiti, 1969, pp. 108–109; Ray, 1976, p. 32).

This value is expressed in African music. Traditional African musical performances are occasions not for passive listening but for participating and doing. Each person contributes only one note, a small part of the whole sound. For a white person from a Western culture, this may appear very inefficient because one person could for instance produce the whole sound with one hand on a keyboard synthesizer. That, however, is irrelevant in this case. The music is a social thing, aimed at expressing cooperation (Tracey, 1990, pp. 36–37).

From the above, it may be hypothesized that traditional African culture nurtures the affective development of children. Gifted programs that under-emphasize or exclude the affective and social dimensions of child development may be seen as contrary to traditional culture and be rejected.

#### *Different Conceptions of Giftedness*

All cultures include individuals who excel and who have special abilities (O'Tuel, Swanson & Elam, 1997). Forbes-Harper (1997, p. 483) states that "recent research has revealed that any concept of giftedness is a product of a society at a particular time." Thus, giftedness would appear to have meaning relative to a given cultural context and each culture should define giftedness in its own image, in terms of the abilities that the members of that culture value at that time. Because of this, throughout history the meaning of giftedness has shifted according to the interests and preconceptions of people using the term. However, most of the definitions that are commonly accepted around the world today have arisen from the interests of Westerners and may not reflect the culture of a certain people. Some definitions refer to certain areas in which high performance needs to be demonstrated. If areas that are considered to be of major importance in a specific culture are excluded such conceptions of giftedness may not be acceptable. Modern technological societies greatly value logical mathematical intelligence and certain forms of linguistic competence. On the other hand, African cultural tradition ascribes greater weight to social than technological facts of intelligence, views child-rearing goals primarily in terms of social skills and regards interactions with people as inherently more important than objects, thus fostering a more socially orientated set of cognitive skills. Defining and identifying giftedness in other cultures is therefore a "cultural and academic

minefield" (Forbes-Harper, 1997, p. 486). It is also feasible that in the modern information age, causing so much interaction with other cultures, the inhabitants of our 'global village' are sharing more common interests than in the past. Thus many African cultures are composed of individuals clinging to traditional values as well as those who value so-called 'Western' ideals and share many 'Western' interests. An African definition of giftedness would thus have to accommodate both groups.

Benedict (in Khatena, 1992, p. 6) reports that "culture shapes man although more slowly man shapes culture as well." In Africa, there is a dearth of research concerning gifted black youths and in the little there is, it is noticeable that the authors attempt to 'fit' black gifted learners to views of giftedness foreign to African culture (for example, Mwamwenda, 1990). It is possible that Africans are shaping their culture towards Western patterns but it would be tragic if they lose knowledge of their original cultural identity in the process. For this reason, it is important to understand how giftedness may have been viewed in traditional African cultures and whether this view is changing.

#### *African Views of Giftedness*

Considering views of giftedness in African countries, one can see the influence and impact of cultural and ethnic motives (Yossufu, 1986; Lumadi, 1998). Many believe strongly in maintaining their traditional past and as such encourage the fundamental and traditional arts of their various cultures such as wood carving, basket weaving, pottery, music, dance and many others that are held in high esteem.

Anim (1992) provides valuable insight into traditional African conceptions and manifestations of giftedness. He describes the custom whereby a young child addresses a visiting chief in drum language while another sings his praises in terms of traditional poems and then, to the rhythm of his companion's drumming, executes a beautiful and very intricate dance. This is repeated for other chiefs attending a festival. Each praise is sung spontaneously with no rehearsal and no prior knowledge except the name of a chief and where he came from. Anim points out that such a performance requires creativity and quick thinking. Another manifestation of giftedness is found in the role of the linguist who is the traditional mouthpiece of the Akan chief (Anim, 1992). As the traditional Akan chief is not allowed to talk directly with his people, the linguist becomes the intermediary. A linguist should have a great sense of humour, be a master of court language, be able to think fast and take quick rational decisions. In short, he should be an accomplished diplomat. A chief's drummer would be required to advise the chief during talks with rhythmic codes on the drum and would likewise have to be a very talented person (Anim, 1991, p. 24). In traditional African culture the concept of giftedness acquires meaning in terms of

performances such as those of the linguist and the drummer.

According to Lumadi (1998), giftedness in individuals is recognized and valued in African culture so long as the ability is used for the greater good of the family and/or the community rather than promoting only the wellbeing of the individual. Thus the cohesiveness of social groups is emphasized again. In the traditional Vhavenda culture, exceptional abilities were encouraged in various fields including sport, art, music, courage and prowess in battle, and leadership. In modern Vhavenda families, the emphasis has broadened to include academic abilities. Child rearing patterns followed by the Vhavenda tend to support and develop high ability in children. These include (Lumadi, 1998):

- Family pride in individual achievement.
- Encouragement to do one's best and strive for excellence.
- Competition.
- Reward for a job well done.
- Valuing persistence and hard work.
- Choosing role models.
- Cooperation and helping one another.
- Building self-esteem and a determination to succeed.

In a study to investigate the effect of gender stereotyping on urbanised black gifted adolescents, Kokot & Kokot (1998) find that the adolescents as well as their families reject traditional roles and support high individual achievement in all spheres.

#### *Elitist Conceptions of Gifted Education*

For some, gifted education is associated with elitist education. For historical and cultural reasons this may be a view commonly held in present day Africa. In colonial times and even thereafter educational opportunities in some instances were provided for the few at the expense of the many. African elites, i.e. those with social status and belonging to ruling families, were mostly assured of an education in Western-oriented systems. Members of such elites, according to Giri (1990, p. 66), owed much of their personal success to their passage through such systems. It is therefore understandable that conceptions of giftedness that result in singling out for special treatment a selected group of children, say with high IQs, may be associated with earlier forms of elite education and seen as reinforcing still existing inequalities and providing for a minority who are already perceived as privileged by virtue of their unique gifts. Tembela (1987, p. 65), in rejecting special schools for the gifted, given an indication of how deep-seated that feeling is by associating such an educational measure with 'intellectual aristocracy' and "a perpetuation of class distinction."

However, perhaps due to the present rapid cultural transition and adoption of 'modern' values, many African families are increasingly keen to support children to become achievers in their particular fields. There is an emphasis on good education, which is seen by many Africans as being the key to a future that allows freedom from the shackles of poverty and other problems of being disadvantaged and those children who have the opportunity of gaining a better education tend to seize it rather than refuse on the grounds of elitism. The support of rapid advancement of black women through affirmative action in South Africa (Kokot & Kokot, 1998) also signals changing social norms and a movement away from communalism—at least in the academic and financial arenas. Therefore, the concept of 'elitism' that is still association with the identification of and provision for gifted children in South Africa at least appears to be a political rather than a social issue.

#### *Different Interpretations of Equal Educational Rights*

The most basic and widely accepted proposal about human rights is the Universal Declaration of Human Rights adopted by the United Nations in 1948. Article 26 of the declaration states that "Everyone has the right to education" (Human rights, 1983, p. 3). The document makes no mention of special provision for the gifted. Principle 7 of the Declaration of the Rights of the Child (1959) states inter alia that "The child . . . shall be given an education . . . on a basis of equal opportunity, to develop his abilities . . ." (Tarrow, 1987, p. 238). Although this could be interpreted to include the gifted, educational rights for the gifted and talented are not directly mentioned in human rights documents. A society that does not provide for the gifted can therefore not be accused of not honoring the idea of equal education rights.

Even if the idea of equal educational rights for the gifted is accepted, people may disagree about what is meant by equal educational rights (Thomas, 1987). For some, equal educational rights means equality of opportunity, i.e. the right to be treated differently according to one's particular abilities and one's particular needs. Equality of opportunity is interpreted to mean not equal, but different offerings and treatment (Bishop, 1989). It may also be expressed in the words: "Help each child to become all that he or she is capable of being." All children are not alike and should therefore not be treated the same. This would imply special provision for the gifted. For others, equal implies equal access to educational opportunities and that everyone deserves a place in the regular educational system. This means that every child, of whatever ability, should have a chance to enter a typical classroom. All learners are therefore admitted to school and all are treated equally, meaning that everyone is treated the same. Those who fail to progress under

regular instruction will usually drop out of school or be forced to repeat their present grade level.

African countries that are struggling to provide greater educational access to their people will probably adhere to the latter interpretation of equal educational rights, i.e. give as many children as possible the opportunity to enter the regular educational system. South African introduced the concept of 'inclusion' to its new post-1994 education system. This policy ensures that all children may receive tuition in mainstream schools, regardless of any barriers to learning that they may experience, such as visual, auditory, physical or other handicaps. It expects teachers to be able to provide support for all kinds of differing dis/abilities in the classrooms, and serves to illustrate the government's interpretation of equality in education. It is thus likely that programs for gifted children would be considered as elitist.

#### *The Goal of Universal Primary Education*

Article 4 of the Convention Against Discrimination in Education (1960) called for free and compulsory primary education. African countries that were signatories to the UNESCO Addis Ababa Conference of 1961 established universal primary education as a regional goal set to be accomplished within a decade (Ahmed & Coombs, 1975). This has not been accomplished in spite of very good achievement in educational access and equity during recent decades. The problem is compounded by the fact that Africa, with the world's highest birth rate, will have doubled its population by the year 2000 (Poats, 1984). The population of Africa at present is about 550 million people of whom the majority are of low socioeconomic status.

In countries that are still some distance from achieving universal primary schooling, equalizing educational opportunity will in these instances probably mean that everyone deserves the same chance to try the standard course of study offered in the schools.

#### *The Priority of Majority Needs*

It is to be expected that educational authorities will give first priority to providing education to the great mass of average learners. Only after facilities have been provided for the 'average majority' can attention be given to special provisions, first the handicapped and then the gifted. In countries that are struggling at present to provide at least 6 years of primary education for all, special provision for the exceptional minority may be postponed indefinitely.

Other reasons for serving the non-exceptional majority before the exceptional also exist. First, the average majority of the population forms a more powerful political body than do the exceptional. The non-exceptional are far larger in number and can exert more effective political pressure to have its educational needs fulfilled than can the exceptional minority. Second, the non-handicapped majority composes the

Table 1. Enrolment Ratios in Sub-Saharan Africa, 1995.

labor force needed for developing a country's economic growth, so that an investment in educating the majority is expected to yield benefits in increased production. Third, as a developing nation desperately tries to enroll all of its growing population of children in school, its educators are hardly able to train enough teachers and print enough textbooks to serve the average majority, much less to finance the more expensive services needed by the exceptional (Thomas, 1987). Enrolment figures for sub-Saharan Africa are given in Table 1 and illiteracy rates in Table 2.

#### *Economic Conditions*

The more affluent a community the more likely it is that a wide variety of special educational services will

Table 2. Estimated Adult Illiterate Population (%) in Some Sub-Saharan African Countries, 1995.

be provided. When resources for education are seriously limited, it becomes a difficult question to decide who should get how much. If resources are equally divided among everyone, an equal share may be too small to be of much practical significance. Training teachers in gifted education will place a further burden on scarce resources because of a longer training period and the need for additional trainers. This will be difficult to justify in the light of a World Bank report that states that in more than half of the countries in sub-Saharan Africa, 50% or more of the teaching staff lack formal training and do not meet the standards the countries themselves require (Rideout, 1987).

#### *Marginalization of Education*

Education systems in some sub-Saharan African states have been criticized for turning out too many graduates with doubtful qualifications of even more doubtful use and that they do so at a high cost that is beyond the means of the national economies (Giri, 1990). Scientists, technicians, economists and others are in many instances trained for a Western-style economy geared to sustained development and high productivity. It appeared reasonable to think that the very existence of more and more professionals trained to cater for the needs of a modern society would help sustain economic growth.

The expected growth however seems not to have taken place. In the seventies, growth slowed in most countries and in the eighties, the superficially modern societies of sub-Saharan Africa declined and in some cases collapsed altogether, according to Giri (1990). On the other hand, informal activity flourished in every sector—in trade, transport and crafts and even in small industries and banking. There was a burgeoning of initiative outside the formal framework and of low-productivity activities in general. A stage has been reached where it is the informal sector that largely dominates employment in the townships of Africa. In addition, the outbreak of wars, political unrest and disruption during the nineties has hardly contributed to economic stability or growth.

Education is being perceived by some as having failed to lead African societies to economic growth and turning out young people whose only prospects are jobs in the informal sector that bear little relation to the training they have received. The result is that the aims of the education system have been questioned, that it has been seen as too expensive and unsuitable and in the process marginalized to some extent. Under these circumstances allocation of scarce resources to gifted education may be seen as a bad investment.

#### **Historical Overview of Gifted Education in Sub-Saharan Africa**

South Africa is the only sub-Saharan African country in which notable developments in the field of gifted education have taken place. After 1910 a sophisticated

education system for whites was developed in South Africa. In spite of the well-developed education system for the whites, little was done to meet the needs of gifted children in that system. Prominent educationists pointed out from time to time that the country could not afford to neglect its gifted youth and that special provision should be made for their needs. In 1918 Dr W. T. Viljoen, Superintendent General of Education in the Cape Province, remarked on the rigid uniformity of teaching in the schools and in his annual report called for the introduction of differentiated courses which would provide for the slow and the gifted learner (Cape of Good Hope Department of Public Education, 1919). In 1931, an article was written by an educator who advised grouping pupils according to their cognitive abilities, as determined by intelligence testing (Kimmins, 1931). Much later, two Presidents of the influential Suid-Afrikaanse Onderwysersunie (English: South African Teachers' Union), G. J. Smit in 1954 and F. S. Robertson in 1963, devoted their presidential addresses to the theme of gifted education and expressed concern that gifted pupils were underachieving and that their full potential was not being developed in the schools.

No significant research on the gifted child was undertaken before the 1940s. The first important work was done by Biesheuvel on African intelligence with special reference to the extent that growth and measurement of intelligence can be determined by factors other than heredity such as cultural milieu, home environment, school environment, nutrition and temperament (Biesheuvel, 1943). Further studies by Biesheuvel on African ability focused on the intellectual potentialities of Africans and the identification and description of research problems in this field. These included the following: mental characteristics of African languages and the influence that they have on the process of thought and structure of the mind, musical ability (e.g. the ability to excel in the manipulation of auditory relations), a psychological study of the manual and perceptual skills involved in arts and crafts and their transferability outside their cultural context, and the high order perceptual and imaginal thinking processes required by traditional African games (Biesheuvel, 1952).

In 1946 the point was made that the education system should provide for the "right of every pupil to undergo school training that enables him to experience a daily task or career that matches his aptitude" (Archer in Coetzer & Van Zyl, 1989, p.147, translated). In the 1950s more academic works appeared. One concerned a study of the intellectually superior school child, with special reference to social adjustment. Venter (1955) experimentally investigated different procedures whereby special provision could be made for gifted pupils and Duminy, who defended his doctoral thesis on psychological and pedagogical aspects of giftedness in December 1959 at the Free University, Amsterdam,

in the Netherlands (Duminy, 1960). Articles concerned with the plight of the gifted child and descriptions of attempts to bring this plight to the attention of teachers and education authorities appeared. To accommodate differences in learners, differentiated education within schools in the white education departments became an aim of the South African education system in the 1950s. This approach was to provide for learner's disparate intellectual abilities, aptitudes and interests and also to provide gifted pupils with more challenging learning matter.

During the 1960s, interest in gifted learners grew considerably. In 1964 the findings of a committee were that (Jacobs & White, 1994):

- gifted children should be homogeneously grouped in primary schools so that teaching methods could be adapted to meet their needs;
- curriculum content should be adjusted for gifted primary school children;
- acceleration and enrichment should be practised as methods of accommodating the needs of able learners in schools;
- secondary schools offering specialized study in the technical, commercial, agricultural, scientific and arts fields be established.

In 1965, the Institute for Manpower Research of the National Bureau for Educational and Social Research launched project Talent Search, described by Lategan (1986) as "probably the largest educational research project yet undertaken in South Africa" (translated from the Afrikaans). This long-term project investigated the academic progress of about 70 000 high ability white Standard 6 (Grade 9) pupils to create a basis for effective special educational provision for gifted children.

From around 1969 Jock L. Omond, a retired headmaster and inspector of schools, accelerated the propagation of the idea of gifted education. Over the next few years he put the case of the gifted to education authorities and the public at meetings all over the country, delivered papers at conferences, and gave interviews over the radio and TV. The educational authorities reacted negatively at first to Omond's pleas so he decided to proceed on his own. On June 14, 1976, he established the Office for the Gifted and Talented in Port Elizabeth with the aim of providing for the gifted on an extra-curricular basis and in an out-of-school setting.

In 1970 the Human Sciences Research Council (Haasbroek, 1988) reported that differentiated education was being practised in different ways at different levels in the various provinces. Following this, various task committees to investigate gifted education were established and further reports were published in 1981, 1984, 1987 and 1988. It is noticeable that the first real attempts to investigate the needs of gifted black

children were made during the 1980s and a report was published in 1988 that motivated the establishment of a special school for black gifted learners.

In 1979, the first National Conference on Gifted Education was organized by the University of Stellenbosch. Gradually a more positive attitude was developing towards gifted education on the part of the education authorities and official recognition was gained with the appointment of the first education planner for the gifted, Dr J. S. Neethling on October 1, 1980 by the Education Department of the Cape Province. At the end of 1980 the Transvaal Education Department followed suit and established extra-curricular centers to provide for the needs of gifted children. Shortly afterwards the province of Natal also established a system to provide for the gifted and similarly the Orange Free State in 1986.

During 1982 and 1983 various developments took place in the Cape Province. Twenty-five schools were selected and virtually given *carte blanche* to introduce and develop gifted education. One of the major tasks of these schools was to provide guidance and support to other schools starting out on gifted education. An editorial board was formed for the publication of *Creata*, the first bilingual journal on gifted education in the world and the first Problem-Solving Bowl, based on the Torrance model, was held. In-service courses were held for principals, teachers and school psychologists (Neethling, 1985).

It was also realized that apart from limited in-service courses for teachers formal training programs needed to be established at tertiary institutions. The first extensive training program for teachers of the gifted was established at the University of Port Elizabeth in 1983. The University of South Africa followed and these universities offer basic modules on gifted education in pre-service education courses as well as specialized training at post-graduate level.

Further impetus was given to the idea of gifted education by the First International Conference on Giftedness (*Ingenium 1000*) that was held in Stellenbosch in 1984. Major inputs at the conference were made by speakers from the United States of America and their influence has been clearly visible in programs that were subsequently established in various parts of South Africa. This was followed by a Second International Conference (*Children of Gold*) in Johannesburg in 1987. Unfortunately, the unstable political climate of this time restricted the number of overseas attendants and impacted as well on the black schools. Even though financial support had been obtained to enable black teachers to attend, boycotts and disruption of many of these schools made attendance impossible.

By the end of the 1980s, it was clear that the provincial authorities responsible for diverse population groups were developing different approaches to gifted child education. These approaches included two

high schools for Art, Ballet and Music, extracurricular centers, parent-driven enrichment programs and enrichment programs for black pupils that were run as outreach programs. Other familiar activities, such as subject Olympiads, Problem-Solving Bowls and Speech and Drama contests were also held in various parts of the country (Kokot, 1994). Leadership courses were regularly offered to senior primary and high school pupils. Furthermore, high school pupils were no longer limited in the number of subjects studied for the matriculation examination. Instead of the usual six subjects, most highly able students were now studying seven subjects, with many sitting for up to ten subjects at the end of their matriculation year.

In view of these diverse efforts, it is not surprising that in their investigation of the 'state of the art' of education for the gifted in member and non-member countries of UNESCO, Mitchell & Williams (1987) found that the "two developed nations that lead the world in level of commitment to gifted/talented education are Israel and South Africa" (p. 532). However, there is no doubt that the same commitment was not in evidence in education departments responsible for black education in the less developed areas of South Africa. It is, therefore, understandable that gifted education was regarded as part of the elitist, white regime.

#### *Other African Countries*

Outside of South Africa hardly any development of note has taken place in the field of gifted education. In Nigeria the National Policy on Education (1981) states that Ministries of Education will, in consultation with appropriate bodies, provide special programs for gifted children (Gwany, 1989). It is not clear whether any further development took place before 1986 when a National Planning Committee of ten members from tertiary institutions was constituted by the Federal Minister of Education. A First Workshop on the Identification and Nurturing of the Gifted was held in 1986 at Kaduna (Adesokan, 1986). A blueprint was outlined and policy formulated on the identification and education of the gifted in Nigeria. According to Oladokun (1987) and Gwany (1989), however, the existing system was not significantly adapted to accommodate the gifted child and nothing of real note has been done to generally encourage gifted education in Nigeria. Adesokan (1987) states that the Nigerian teacher is unlikely to assume the function of identifying and nurturing giftedness unless specific attention is given to gifted education in teacher training.

In some African countries with limited secondary school places pupils attending those schools are a highly select group. Secondary education may in those circumstances be regarded as a form of special education provision for a group of pupils which may resemble the highly able in some respects. In Tanzania a quota system exists for selection to secondary school.

Such a scheme was necessary to prevent most of the places going to educationally wealthy areas in the country. The poorer areas can now send pupils for secondary education even though their academic achievement may be well below those of some pupils in the richer areas who are not selected. Furthermore, better-equipped primary schools tended to send a disproportionate number of pupils to the secondary schools. To achieve more equitable distribution of places to the secondary school, the top pupil from each primary school is selected to go on for further education. In this way children in every school in Tanzania have at least some chance of making it to secondary school (Bishop, 1989).

Yoder (1986) states that secondary education and certainly post-secondary education was, by definition, education of the gifted during the pre-independence days of Botswana. Those few individuals who rose to the top and who were selected for further advancement of their education were typically those who displayed exceptional potential. Often, it was because of this potential that they received the educational opportunities that they did. It is true that social status and membership in the ruling family also affected educational opportunity, particularly in the very early days. In time, as the concept of education became more broadly accepted, however, access to schooling became more dependent on factors such as academic ability. Access to advanced schooling, particularly, was influenced by academic potential. Advanced education, therefore, was available primarily for academic achievers who could be said to be academically gifted.

According to Yoder (1986) Botswana has no programs that are identified as being specifically for the benefit of the gifted. The one possible exception to this is a private secondary school in the Gaborone area that offers a moderately accelerated program for pupils who demonstrate the required aptitude. Those pupils selected for this program may compress a five-year secondary school program into four years. Additional Mathematics was offered in some schools at one stage but this has been dropped. The training program of teachers' colleges in Botswana does not include gifted education.

Gifted education in Kenya seems to be in the embryonic stage. Interest has been generated amongst teachers, parents and the public by means of conferences. A first conference was held in 1991 and the Second Eastern African Conference on Gifted and Talented persons was held in August 1992 in Nairobi on the theme of "Caring, educating and harnessing gifted and talented persons for national development." Objectives of the conference were the following:

- To develop and increase public awareness on the plight of gifted and talented persons.
- To encourage individual and/or collaborative research work in the area of giftedness and talent.

- To encourage efforts to establish and implement intervention programs.
- To identify in general terms the handicaps which gifted and talented people experience, and to suggest possible solutions.
- To encourage the utilization of the gifted and talented in society for national development.

### The Search for an Identification Procedure

Giftedness is culture-specific. What is recognized as gifted behaviour in one culture or environment may be beside the point in another. An identification model or procedure for giftedness that does not attend to a specific sociocultural context would therefore fail to identify the gifted in that context. This is especially relevant in traditional African society.

#### *Identification of the Gifted in Traditional African Culture*

Certain characteristics are highly valued in traditional African society. These include a quick wit, wisdom, humour, an active, dynamic disposition, leadership, linguistic excellence, one who knows everything, and one who is good with his hands around the house (Anim, 1992). Children who are seen to reflect these characteristics may be given names accordingly. For example, parents may give their boy the name Okabae (English: he has returned) because their child showed exceptional intelligence that led them to believe that a wise and long dead member of the family had returned. Names can therefore be an indicator of intelligence (Anim, 1991).

In traditional African society gifted children were selected for very special roles and could be found at a very early age serving in the chief's court, learning the intricate life styles of a courtier. Certain roles, for example, that of the linguist and drummer, cannot be inherited. It is something that a person becomes because of the qualities that s/he possesses. The linguist of the village who is the spokesman and adviser of the chief will be selected on the grounds of his wisdom, diplomacy and quick wit. Likewise the drummer who transmits messages in drum language to the chief during discussions will be selected on the grounds of possessing certain special qualities (Anim, 1991).

#### *Pre-1994 Identification Procedures*

A general intelligence test based on the South African Individual Scale has been developed and standardized for nine African languages by the Institute for Psychological and Edumetric Research of the Human Sciences Research Council (HSRC), e.g. the Individual Scale for Xhosa-speaking pupils (1988). These tests could be described as culture-fair but are generally not accepted to be culture-free for various reasons. For example, these tests may be regarded as favoring an inner locus-of-control orientation which is typical of Western

culture. Other tests developed by the HSRC that may be applied to assess Black secondary school learners' abilities are the Guidance Test Battery for Secondary Pupils (GBS) in Grade 10, the Scholastic Aptitude Test Battery (SATB) for learners in Grades 4/5, 6/7 and 8/9 and the Academic Aptitude Test (AAT) for Grade 12 learners. The SATB 4/5 has been standardized for seven language groups, namely Northern Sotho, Southern Sotho, Tswana, Tsonga, Venda, Xhosa and Zulu. These tests are used for guidance purposes and not specifically to identify gifted pupils. Tiale (1990) is of the opinion that the above-mentioned tests are based on Western culture and therefore cannot reveal the full ability of black children.

A more flexible approach to the identification of gifted pupils was followed by the Cape Province Education Department (now the Western Cape Education Department) in South Africa. Instruments and procedures that were used include IQ tests, Torrance Creativity Tests, assessment of reading and spelling age, assessment of mathematical ability and further teacher or parent assessment. Formal application of these, however, only continues if it is required to clear up doubts or to assess specific abilities. Where identification is obvious testing will not be completed.

A more formal approach was followed by the Transvaal Education Department in South Africa (now the Gauteng Department of Education). The first phase of the identification procedure required the collection of data about academic achievement in school, characteristics of a child, and by means of teacher and peer evaluation, using checklists. Secondly, a panel of evaluators at a school would identify those nominated as gifted on the basis of the data available. In the third phase all particulars of the pupils identified in phase two were sent to the regional office of the Educational Support Services for a final selection of pupils. This department implemented this identity procedure to all Grade 3 pupils for selection for admission to gifted programs run at extra-curricular centers from Grade 4 onwards.

In most African countries the task of identifying the gifted presents a mammoth problem (Anim, 1992). An acute shortage of teachers and a near total absence of school psychologists or guidance counselors mean that identification procedures used in developed countries are largely non-existent. The only means remaining for schools are the teacher's cumulative assessment of a child's achievement and, in most cases, the teacher's intuition. No specialized way is possible of identifying the gifted in the large classes in which over-extended teachers must function.

#### *Recent Research on Identification*

Many studies concerned with issues and aspects of gifted education have been conducted in South Africa amongst the white population group. There has, however, been a dearth of research concerning black

gifted children and even more rare are studies completed by black researchers. One major area of concern over the years has been the lack of a definition and identification procedure that is valid for African culture.

#### *The Development of Principles for the Design of an Instrument to Identify Gifted Black Children*

Tlale (1990) undertook an investigation in South Africa to determine principles for the design of a culturally relevant instrument to identify gifted black secondary school children. He identified six principles, namely that the instrument should

- measure cognitive and metacognitive functions;
- be divided into subtests, each measuring a specific ability;
- be culturally appropriate, i.e. based on the socio-cultural environment of black children;
- use appropriate language, i.e. be written in the first language of the child;
- effectively discriminate between children of different ages while taking into account language development in particular;
- avoid biasing factors found in rural and urban cultures (Tlale 1990; pp. 115–119).

These principles are applied to design an instrument to identify gifted Tswana secondary school learners (ages 13–17 years). The instrument comprises six tests. The first five tests are verbal tests and similar to the first five tests of the Senior South African Individual Scale-R (SSAIS Revised); the sixth test is similar to the eighth test (Absurdities) of the SSAIS-R. The above-mentioned six tests of the SSAIS-R were used as a basis for the design of the instrument because they are primarily verbal or composed of pictures which can easily be adapted to African culture (Tlale, 1990). The tests are designed to be administered orally and individually.

After empirical application and testing, the researcher concludes that it has been proved possible to design an instrument, written in Tswana and based on black African culture, to identify gifted Tswana secondary school learners. Nor reference, however, is made to the validity of the instrument as an indicator of giftedness. The researcher also concludes that, as black people in South Africa share a common culture with only a few variations, the instrument can be translated and adapted to other African languages.

#### *Moving Away from IQ Testing*

More recently, a study has been completed that attempts to identify giftedness without resorting to tests. Lumadi (1998) studied the Venda culture to ascertain what cultural and social factors contribute to the development and nurturance of giftedness. He studied identification models described in the literature and concluded that Dabrowski's Overexcitabilities and Gardner's Multiple Intelligence Theory (MIT) are valid

to the culture of the Vhavenda. As a result, he was able to compile a checklist of attributes that would enable teachers to recognize signs of high ability. A qualitative study was conducted with six high school learners. He also concluded that the views of Tannenbaum (1983) and Kokot (1992, 1994) were appropriate to the Venda culture and recommended that either be adopted by African cultures as being suitable definitions of giftedness.

#### *Predictors of Performance of Disadvantaged Adolescents*

Skuy and his associates (Skuy et al., 1990) conducted a study at the University of the Witwatersrand in Johannesburg, to determine which of Feuerstein's Learning Potential Assessment Device (LPAD), standardized ability tests and ratings of temperament, creativity and self-concept were significant predictors of performance. It was hoped that the study would provide the basis for developing an appropriate assessment battery for the identification of suitable candidates for a gifted program.

Of the 300 children participating in the Soweto Gifted Child Program, 100 were randomly selected for inclusion in the sample. Subjects were 13–18 years of age and of low socioeconomic status. Performance in the Soweto Gifted Child Program (SGCP) was the criterion against which the predictive value of the independent measures was determined. The findings of this study corroborated those of Skuy, Kaniel and Tzuril (1988) in Israel by demonstrating the value of the LPAD and, in particular, the Organizer, for identifying giftedness among disadvantaged children.

These studies are limited and represent an initial stage in the much-needed research on gifted black African children. More research needs to be encouraged, especially by black academics who understand their culture, to validate these early findings and broaden knowledge relating this neglected group.

#### **Nurturing the Gifted**

From the discussion of historical and current issues that impact on the provision of education in sub-Saharan African countries one may conclude that very little or no formal provision for the gifted will be made in most of these countries. As already indicated South Africa is the exception in this respect that the gifted were relatively well served by formal and non-formal programs in the old regime. Outside of the well-developed and, for many years, well-funded provincial Education Departments serving mostly the white sector of the population, universities, parent/community associations and private sector groups also provided for the needs of the gifted in various ways.

Although many of the programs have been abandoned due to withdrawal of government funding, it is worth describing certain of the long-term programs that were successful. Programs and opportunities for gifted

learners which are still in existence, but which are of limited scope or shorter duration are not described. These include the following: olympiads (e.g. mathematics, accountancy), competitions (e.g. history, music, choir) art exhibitions, science expo's, problem-solving bowls, leadership seminars, writers' workshops, parent-driven enrichment programs and publication opportunities (e.g. *Wakening Word; Voices from young Africa* (Mda & Van Wyk, no date), youth orchestras and business/stock market games.

#### *Formal In-School Programs*

##### Four-area Curriculum Enrichment and Extension Model

This model was implemented by the Cape Education Department and was based on a wide, flexible interpretation of giftedness. It made provision for the gifted at four levels referred to as areas (Meintjies, 1988; Mentz, 1991). Area 1 provided for all pupils to receive training the thinking skills, problem-solving, research skills, creativity and life-skills (communication, interpersonal relationships). This area formed the basis of the gifted education program. Area 2 was aimed at the top 10–12% of pupils and represented a subject-directed approach. Enrichment and acceleration were provided in the regular classroom situation in each subject and every grade. Area 3 was more child-directed and allowed for a variety of withdrawal and grouping arrangements in-and out-of-class and school. A changing group of pupils was withdrawn for special and inter-school activities, taking into account specific giftedness. Area 4 attempted to provide for the exceptionally brilliant pupils by means of individualization and mentors. These pupils qualified for acceleration. Gifted underachievers received specific attention in the Area 4 program.

Support for teachers was provided by coordinators appointed and paid by the Education Department. They were based at regional Teachers' Centers. Additional support was offered by the Psychological, Educational Guidance and Curriculum Services of the Education Department. The main task of the coordinators was to equip teachers with the skills, strategies and techniques that enabled them to integrate activities for the gifted with the normal teaching program in the school. Workshop, lectures, talks, consultations, personal interviews, advice and information relating to any aspect of gifted education were some of the services provided, not only to teachers but also to parents, pupils, private and tertiary institutions or any other interested organization.

##### Special Schools

In some African countries special schools were established with the purpose of providing a model for other schools to follow. These schools were given various names such as Apex institutions, Special or International Schools. Schools in these categories include

King's College at Yaba in Nigeria, Suleja Academy at Abuja in Nigeria, Prince of Wales College at Achimoto in Ghana, Makerere College in Kampala, Uganda, and Waterford and St. Mark's in Swaziland. Although the establishment of these schools was to the advantage of gifted children, many of them very soon became preparation grounds for university entrance examinations. Cognitive abilities were highlighted and in the process those gifted in other areas lost interest and became underachievers (Anim, 1992). Whether these special schools get their fair share of gifted pupils is unknown. Special schools that are privatized are very expensive and only the financially well-off can afford to send their children to them.

In Ghana available places in secondary schools are so few that clusters of primary schools developed called Preparatory, International or Experimental Schools. The primary purpose of these schools was to prepare pupils for the common entrance examination to the secondary school. These schools do not particularly provide for the gifted and talented.

In 1993 in Johannesburg, South Africa, the Rand Afrikaans University initiated a special secondary school for academically talented black adolescents, known as Raucoll. Funding was obtained from the private sector that considers the school to be an ideal opportunity for training future black business leaders. Subjects offered are English, Afrikaans, Mathematics, Science, Accounting and Business Economics. Top achieving Grade 7 pupils (mainly from schools in Soweto) form the pool from which successful pupils are selected. Part of the admission criteria includes a financial means test as pupils must be drawn from families of low socioeconomic status. Success at matriculation is expected so if a pupil fails to thrive at the school, he or she may be referred to nearby state schools after Grade 9.

In 1995, Dr Shirley Kokot established Radford House, a primary school for gifted children ages 4–13, in Johannesburg. This was in response to parent requests following the rapid increase in problems manifested by gifted children in classrooms subjected to increasing teacher-pupil ratios and the rapidly increasing influx of previously disadvantaged black children. Teachers faced with the problem of a high percentage of children with poor English and very limited academic skills in the same class as gifted and 'average' children proclaimed that the situation made it impossible to adequately accommodate the gifted. This led to many behavioral and emotional problems amongst bright children.

Radford House serves children of high potential by keeping class sizes small (the teacher-pupil ratio is a maximum of 1–16 but averages at 1–12); focuses on skills rather than content (including thinking skills and research skills) and promotes discovery learning and exploration. The unique teaching approach integrates Howard Gardner's Multiple Intelligence Theory into a

thematic approach where the children are guided to be active rather than passive participants in the teaching process. Extracurricular activities, aimed at providing the children with an holistic education, include sports (ball skills, cricket, soccer, hockey, tennis, swimming and netball) as well as chess, choir, public speaking, debating, art, drama, a wildlife club, and a French language club. Ballet and Karate are offered at the school by private teachers. The school receives no funding and operates purely on school fees.

#### Special Schools for the Arts and Commercial Subjects

In the province of Gauteng in South Africa provision for specific talents in fine and performing arts, ballet, music and commercial subjects is made by means of two special schools (in Pretoria and Johannesburg) which cater specifically for these areas of giftedness. Originally, the Arts and Ballet school in Pretoria was separate from the Commercial High schools but owing to lack of funds, these combined to share a single school building after 1994.

#### *Formal Out-of-School Programs*

##### Extra-Curricular Centers

The Transvaal Education Department in South Africa made provision for the gifted in out-of-school settings. These aimed to provide enrichment in various fields not normally encountered by pupils in school (e.g. Philosophical Studies, Astronomy, Electronics, Petrochemical and Geological Studies, Money and Banking, Drama etc.). These centers were situated in the larger cities in the province. Only pupils who were identified as gifted according to a three phase selection procedure could attend the centers. Classes were offered after school hours, once or twice weekly for an hour at a time. Curricula were designed jointly by curriculum experts, universities, staff attached to the centers and the private sector.

Certain of the centers ran courses were during school vacations to enable children from outlying areas to have the enrichment opportunity and interact socially.

The center in Pretoria, serving 2000 pupils annually, has been closed down. The remaining centers are unsure of how long they will be able to function, owing to lack of state funding.

The Orange Free State had one enrichment center situated in Bloemfontein. This center included a boarding establishment so that groups of gifted pupils from all over the province could attend a week-long course twice a year. This center has been closed down.

In 1984, Dr Cedric Taylor established an Academic Vacation School at the University of Port Elizabeth. This was a two week residential program that was attended by Grade 9–12 gifted pupils every year from all over South Africa. The school was funded by the University Council and by sponsors from the private sector. The objectives of the school were to provide the pupils with intellectually challenging experiences

within the academic framework of the university; to promote good relationships between black and white pupils in South Africa and to create the opportunity for pupils from disadvantaged communities to learn and live together with their intellectual peers from more privileged communities and thus to facilitate their transition from school to university. After 1994, the Vacation School changed to a facility for only black, previously disadvantaged pupils.

#### The Office for the Gifted and Talented

Voluntary parent or community associations played a pioneering role in the 1970s in providing for the gifted in South Africa. During this decade the educational authorities were opposed to the idea of special provision for the gifted in schools. The parents and community responded by establishing parent/community associations in various big centers that provided extra-curricular activities for the gifted. The pioneer in this respect was Jock Omond, who established the Office for the Gifted and Talented in Port Elizabeth, South Africa, in 1976. The Office offered courses and lecturers on a variety of topics and arranged visits to centers of interest. Periodicals, books and newspapers from all over the world were scrutinized and a newsletter was published which summarized articles from these sources that were of possible interest to parents and teachers. A collection, possibly unique in the world, of 28 volumes of approximately 12 000 press cuttings on gifted education from all countries was regularly brought up to date. The collection is available for research and study by appointment. The death in 1990 of Omond who was the driving force behind the Office, signaled its discontinuation.

#### The National Association for Gifted and Talented Children in South Africa

In 1992, Shirley Kokot, a senior lecturer responsible for teacher training in gifted child education at the University of South Africa, Pretoria, identified the need for networking advocates of gifted education throughout Southern Africa and launched the newsletter *Excedo* (English: We go beyond). The mailing list of this newsletter grew to over 2000 addresses. In 1997, Dr Kokot organized a National Conference at the University of South Africa in Pretoria to address the plight of the gifted in the light of the new dispensation. A result of the conference was the formation of the National Association of Gifted and Talented Children in South Africa (NAGTCSA). Dr Kokot was elected President and the *Excedo* newsletter became the mouthpiece of the Association. Consequently, NAGTCSA representatives were able to represent gifted children and their families in discussions regarding policy decisions in education. Gifted learners continue to fall under the structures established to provide for education for learners with special

educational needs (ELSEN) in South Africa but the focus in education discussions and policy documents is on 'disabled' and 'disadvantaged' learners. Because of this emphasis, mention of the highly able has been almost non-existent in the various new policy proposals. The final policies regarding special needs education are currently being drawn up and the success of the lobbying by the NAGTCSA is awaited.

#### Growth of Children's Potential (GCP)

In 1982 Stan Edkins, a retired headmaster, in liaison with the Department of Education and Training (the department responsible for black education) provided the impetus for a Saturday enrichment program in the sprawling black township of Soweto. It became known as the Soweto Saturday School. In 1983 a second program was started in Alexandra, an overcrowded black ghetto, a third in 1988 in Northern Soweto and a similar program was started in the Johannesburg suburb of Bedfordview for pupils from Daveyton, yet another black township. These projects developed into what was called the Gifted child program. In 1992 the name was changed to Growth of Children's Potential.

The focus of the program is the previously disadvantaged gifted pupil from black township schools who, because of the inadequate schooling system and deprived sociopolitical background, would not reach potential.

The selection process consists of an initial screening by the school whereby the top 2–3 academic pupils from each school are invited for further assessment using a general intelligence test normed in South Africa and the Torrance Test of Creative Thinking. The top 25 pupils per area and per grade are selected.

The main components of the program are Saturday morning enrichment of academic areas. An integrated studies themes approach is used which dovetails with the syllabi of the state schools. Afternoon special interest groups follow the morning program and after a light lunch, the pupils take part in relaxing and creative activities. Workshops are run by tutors, volunteer community people and experts and include current affairs seminars, drama, chess, dance, art, swimming, other sports and nature awareness. Excursions, camps and cross-cultural activities are also organized during the year.

All Grade 7 and 8 pupils on the program are tested annually using a battery of aptitude tests. Based on the test results and in consultation with GCP center directors, pupils are selected to write the private school entrance examinations. In 1991 thirty of these pupils were accepted into private schools and scholarships secured for twenty-one.

The GCP achieved measurable success and stability in its first 10 years with over 600 pupils being accommodated in their programs per year and another 400 in programs run in other regions using the same model. The future of the GCP is uncertain.

#### Non-Formal In-School Programs

##### Thinking Actively in a Social Context (TASC)

A Curriculum Development Unit (CDU) under the co-directorship of Belle Wallace and Harvey B. Adams was established at the University of Natal, Pietermaritzburg, South Africa in 1985 with the overall aim of undertaking research, teaching and community-service activities to help teachers maximise the extent to which all pupils develop their potential. Under the broad aim of the CDU and in the light of the perceived needs of high school pupils an initial pilot project was launched in 1986 to develop a course to teach thinking skills to pupils in Grade 10. The focus was on developing higher levels of thinking skills and problem-solving strategies amongst black pupils in Kwazulu Natal schools (Adams & Wallace, 1991). The TASC program has since been revised and its aims have been extended to develop in the pupils certain attitudes towards learning (in all contexts, not only the school); basic thinking skills necessary for making sense of experience; tools for effective thinking and problem-solving and metacognition.

The extended TASC program also aimed to improve the effectiveness of teachers as facilitators of children's 'learning to learn'. Short-term adaptation and long-term reconstruction of the curriculum is seen as part of the TASC program (Adams & Wallace, 1991). According to the authors the program is based of Vygotsky's work on the development of higher levels of thinking and its connection to social transaction, Feuerstein's theory of cognitive modifiability and the concept of mediated learning experiences, and Sternberg's theory of intelligence (Adams & Wallace 1988, p. 132).

Basic underlying principles of TASC are as follows:

- Adopt a model of the problem-solving process and explicitly teach it.
- Identify a set of specific skills and strategies and give training in these.
- Develop a vocabulary.
- Give ample practice in both the skills and the strategies using situations that are significant and relevant to the learners.
- Give attention to the motivational aspects of problem-solving.
- Progress in the teaching from modeling by the teacher, to guided activity by the learner and eventually autonomous action by the learner.
- Assist the learner to transfer skills and strategies to new contexts.
- Emphasize cooperative learning in small groups.
- Encourage self-monitoring and self-education.
- Require learners to develop their metacognitive knowledge (Adams & Wallace, 1991, p. 107).

Several courses based on underlying principles of TASC have been developed and tested. These courses, each spread over a 5 day (25 hours) period, were taught

to high achieving white and black Grade 10 pupils. Adams & Wallace (1991) state that the outcomes were similar in each case, namely rapid learning, high motivation, improvements in self-image and lasting improvements in performance on specified cognitive tasks. No statistics are provided to substantiate these claims. It is, however, mentioned that an evaluation by members of the Schools' Psychological Service teachers, the pupils and the researchers revealed certain difficulties. Firstly, it was felt that pupils not already achieving highly within the school system for whatever reason (e.g. inadequate mastery of English) would need a foundation course in basic thinking, and assistance in achieving oral fluency in English. It was also felt that gains made during the course would be rapidly dissipated unless constant call was made upon the newly acquired skills and metacognitive knowledge during the pupils' subject lessons.

A major pilot course was subsequently run for a mixed ability Grade 10 class of 40 black pupils. This extended over a 6 week period consisting of two 2-hourly sessions after school each week. The researchers state that an evaluation of the course again revealed that the approach was highly successful for those pupils already achieving at a relatively high level and with a reasonable command of the English language. The remainder progressed at a much slower rate. No statistics are given.

Following this, the work of the program was expanded in two directions: the first four years of the 5 year secondary school curriculum will be included in the program of instruction; and secondly, the syllabi of all major school subjects will be examined to identify and develop opportunities for building the use of the newly acquired skills into regular subject lessons (Adams & Wallace, 1991).

The TASC program represents a systematic, multi-phase model of problem-solving, incorporating basic thinking skills and tools for effective thinking. The researchers claim that there are good grounds for believing that the TASC approach has the possibility of achieving significant changes in the capacity of pupils to benefit from their schooling, and the ability to meet problems in their day to day existence. This type of research is important especially to the South African context, where the majority has not been adequately schooled in either content areas or higher level thinking skills. This research is continuing.

#### Future Development

A number of issues have been described that emanate from the political, historical and cultural context of Africa and that have a direct bearing on the provision of education for the gifted and talented. In general, those issues seem to imply that gifted education will probably not be a priority item on the education agenda of most African countries in the near future. A restructuring of gifted education on a broader base and

contextualized for the needs and priorities of a developing country may be needed to establish legitimacy in future. Some aspects that need to be researched in this respect are briefly outlined below:

- Linking gifted education programs to national development needs and traditional culture

National Service Schemes that aim to relate education to practical service to the nation and to promote national unity have been established in Ghana, Nigeria and Sierra Leone (Anim, 1992). The restructuring of programs for the gifted within the wider context of national developmental needs may ensure the legitimacy of such provision in the education system. Likewise, gifted education may be linked to the traditional social structure of *ujamaa* and the improvement of the quality of life of the whole community.

- Building on the strengths of African culture

Competencies and attitudes that are highly valued in African culture and that can be utilized in the development of gifted programs are social-affective competence, interpersonal intelligence and orality (e.g. the *Mukama*—the tradition of oral history and poetry) (Bhola, 1990). Building on the strengths of African culture may increase the relevancy of gifted programs. Traditional orality, for example, could be developed in the context of a modern democratic state in the form of public and political oratory. At the same time programs should also augment those kinds of intelligence that are traditionally not favored in the African culture, e.g. technological competence.

- The integration of gifted programs in regular classroom teaching

Gifted education should be seen to be affording all pupils the opportunity to participate in and gain from enrichment and extension and to discover and develop their potential. Therefore special programs should not be provided separately for a select few but be open to all who are interested in and able to benefit from such opportunities. Models need to be researched that integrate gifted programs in regular classroom teaching.

# Programs and Practices for Identifying and Nurturing Giftedness and Talent in Latin American Countries

Eunice M. L. Soriano de Alencar<sup>1</sup>, Sheyla Blumen-Pardo<sup>2</sup> and Doris Castellanos-Simons<sup>3</sup>

## Introduction

We are beginning the third millennium and gifted education in Latin American countries is still very heterogeneous and complex in its development. While Brazil, the largest and only Portuguese speaking country, is consolidating its special services in different levels of education, and other countries such as Peru, Cuba, Mexico, and Argentina, have shown a significant progress, others have little or no provision at all for their gifted and talented population.

The purpose of this chapter is to provide an overview of gifted education in Latin American countries. It will focus first on Peru and South American Spanish spoken countries. Following, gifted education in Brazil will be described as the country which offers the greatest diversity of programs for gifted students. Next, attention for the gifted and the talented in Cuba, Central, and North American countries will be presented. The chapter finalizes with issues and perspectives on gifted education in Latin America.

## Gifted and Talented Education in South American Spanish Spoken Countries

Do the gifted make the country, or does the country make the gifted? This question becomes dramatic when we consider the intellectual functioning levels of the majority of South American children, who, beginning the third millennium, live under poor conditions (Pereyra, 1987; Thorne & Blumen, 1996; Casassus, Froemel, Palafox & Cusato, 1998).

The South American Spanish spoken countries are mainly multicultural and multilingual. Peru, Chile, and Venezuela, among other Andean countries, are passing

through an Educational Reform sponsored by many international agencies, in which constructivism plays a very important role (Cardó, 1990; Peruvian Ministry of Education, 1995). Dramatic reduction in the negative indicators of schooling, such as absenteeism and school failure, has been exhibited in these countries, and the goal of universal education is close to being achieved (Blumen, 1998a).

Several attempts to nurture the gifted and talented can be seen in Peru and other South American Spanish spoken countries. Some of them based on scientific research coming from university research centers (Zubiria & Gonzales, 1982; Samper, 1987; Mönks, Ypenburg & Blumen, 1997), or coming from technical institutes (CONCYTEC, 1989, 1998). Others came from the government and are politically influenced (Gonzales, 1991; Ruiz, 1991), and very few come from enterprises or private institutes (i.e. *MENTE FUTURA*, Fundación para la Creatividad y el Talento, among others) and have a hands-on, practical approach (Blumen, 1999b). However, all of them are significant attempts to meet the needs of the gifted and talented of the region (Alencar & Blumen, 1993).

## *The State-of-Art of Gifted and Talented Education*

Provisions for nurturing the gifted and talented in South American Spanish spoken countries began in the late 70s under the influence of Renzulli's theory (Renzulli, 1978). However, due to the multicultural diversity of most of the Andean countries, the need to consider the context as an important factor to assess high ability focused the attention on models which considered the context as an important factor to explain high ability, such as Mönks Interdependence Triadic Model (Mönks, 1992) among others.

The development of educational policies and programs for the gifted and talented in South American Spanish spoken countries varies greatly. While policies are not essential to the existence of programs for gifted learners in the classroom, countries such as Peru,

<sup>1</sup> Catholic University of Brasilia, Brasilia, Brazil.

<sup>2</sup> Catholic University of Peru, Lima, Peru.

E-mail: sblumen@amauta.rcp.net.pe

<sup>3</sup> Pedagogical University Enrique J. Varona, Havana, Cuba.

Colombia and Venezuela, which have legislation-based policies appear to offer better programs according to the educational needs of the gifted and talented.

Peru is leading the South American Spanish spoken countries in the education of the gifted, with a broader provision of programs, both in the public and private school system. Other countries such as Venezuela and Colombia, that first began with special programs for the gifted and talented, have deactivated most of their programs due to financial difficulties; and others, such as Chile and Argentina, have isolated efforts in the private school system. However, there are still countries in the region, such as Ecuador, Bolivia, and Paraguay, which do not provide their public schools with special programs for the gifted and talented learners.

#### *Argentina*

Towards the beginning of the year 2000, three private institutions were created to attend the needs of gifted children in Argentina: two in the capital city of Buenos Aires and the third in the province of Mendoza (Kloosterman, 1999). They are all private institutes whose main goal was to identify and encourage the abilities of the gifted children coming from the middle and middle-upper class. The identification and attention programs were based on Renzulli's (1978) conception of giftedness and the methodology involved parents and teachers counseling services. In 1994, the First Iberoamerican Conference on Talented Children was held in Buenos Aires. Later, the First International Conference on High Intelligence and Education was organized in Mendoza (Kloosterman, 1999). However, the public sector does not yet provide a comprehensive program for the gifted, and the great majority of gifted and talented children in Argentina, most of them coming from poor environments, are still waiting to be attended by the public sector.

#### *Chile*

Since 1964, Chile has attempted to fulfill the gifted and talented needs, led by Dr. Gamba, who founded The Chilean Institute for the Gifted. In 1979, the Andes-Chile National Association for the Development of the Gifted Education, as well as the Latin American Association for the Integral Development of the Gifted was founded; the following year, Supraxia Universal, an Institute for gifted youngsters and adults from all countries was also founded. However, most of these institutes were deactivated in the following years. In 1985, a new method for developing gifted behavior from the first days of life was put in practice by Dr. Gamba (1991) who is promoting his method in the other Spanish spoken countries of the region.

#### *Colombia*

In 1986, the Alberto Merani Foundation for the Development of Intelligence was established with the

goal of being an enrichment center for 12 year olds and older gifted children. The foundation was developed based on the results obtained in a study about the cognitive abilities of 14- to 15- year old high school students, which indicated a delay in the cognitive development due to the adverse living and schooling conditions. In 1987, the First International Conference on Intelligence was organized. This conference was the starting point for the creation of the Institute for the Gifted Children in Bogota, which had started its activities in the previous year. The activities of the foundation are continuing, and focused on the validity of their pedagogical proposals.

#### *Peru*

Peru has quickly developed a concern about gifted and talented children (Blumen, 1995, 1997, 1998a, c, 1999b). In the past seven years, changes of misconceptions and efforts to understand and nurture the gifted and talented have been exhibited, both in public and private education, as well as in the mass media. Although there is a tremendous gap between public and private education (Blumen, 1996, 1999b; Thorne & Blumen, 1996), it is important to recognize that the Educational Reform which began in 1993 nationwide has stated the attention towards the individual needs of the learner (Peruvian Ministry of Education, 1995).

Research on creativity expressed through artistic tasks began during the Educational Reform of 1972 in an attempt to achieve the integral education of the student. In the first half of the 1970s, theoretical and methodological proposals were submitted and the Ministry of Education with the former Federal Republic of Germany, carried out a project on the Education for the Arts. Since 1978, the research carried out in Peru was experimental and comparative. The relationship between variables such as the demographic and socioeconomic level and creativity were examined (Stahr, 1979). In the 1980s, various mediating and conditioning processes were incorporated in the research (Blumen, 2000; Neuhaus, 1982).

In the mid 80s, the first research in the field of gifted education was carried out on a national basis to identify the gifted and talented, involving 3,000 children. Theoretical and methodological proposals aimed at achieving a complete use of human resources to improve the development of the country (CONCYTEC, 1989; Pereyra, 1987).

The most important result of this study took place in 1983, when a Law of Education for the highly able was established (Ministry of Education, 1983). Then, enrichment educational practices began in both public and private school systems. Although limited in number, these programs represented the first attempts to detect and attend the needs of the gifted and talented children in Peru (CONCYTEC, 1989; Gonzales, 1991; Ruiz, 1991). In the early 90s, research focused on the development of creative abilities and on creative

behavior, and a more practical approach to research has emerged.

More recently, the Catholic University of Peru in cooperation with the Catholic University of Nijmegen, has supported most of the research on gifted education in Peru (Blumen, 1996, 1998b, 1999a). As a starting point, doctoral research in the field began in 1994, under the supervision of Prof. Dr. Franz Mönks. Two years later, the First Symposium *Creativity, Intelligence, and Talent* was organized, sponsored by the Graduate Program of Psychology, at the Catholic University of Peru. In addition, from then on, the symposium is organized on a yearly basis.

In May 1997, an experimental teacher training workshop, which benefited 3,000 children and 100 teachers was developed as the first effort to train regular public school teachers to meet the needs of the disadvantaged gifted and talented students. This experimental workshop was sponsored by the *Teacher Training National Plan (PLANCAD)*, the *German Cooperation Agency for Education (GTZ)* and the *Catholic University of Peru (PUCP)*, coordinated by Dr. Eva Gefferth and Prof. Sheyla Blumen. The follow-up and the evaluation process results were positive and strongly recommended application on a national basis (Blumen, 2000), and were introduced as a relevant topic in the regular national teacher training programs.

Later, in December 1997, the book *Nuestros niños son talentosos* (Mönks, Ypenburg & Blumen, 1997) was published by the Catholic University of Peru. This was the first book in the country to call attention to the characteristics of the gifted and talented to promote appropriate educational programs. During 1998, two workshops on gifted and talented education showed that the need to train teachers was increasing dramatically. In 1999 *Mente Futura* started its functioning with a dynamic program of activities involving identification, differentiation and training workshops on the needs of the poor gifted children attending public schools of both, Lima City and the Peruvian Provinces.

In January 1999, the *European Advanced Diploma in Educating the Gifted*, sponsored by the *European Council for High Ability (ECHA)* and the University of Nijmegen, and coordinated by *Mente Futura* was started in Lima City. The *Leon Pinelo School* of Lima provided the infrastructure and the well-equipped Auditorium for the ECHA meetings to take place, in order to train teachers from the region in gifted and talented education. The school, very well-known for its integral philosophy on child development, was also open for the candidates to visit as a relevant setting or for practicing purposes (Robotics, Special Advanced Science or Maths programs, Visual arts enrichment programs, among others).

Peruvian ECHA Diploma candidates come mostly from the public sector, although there are some from the private sector; they belong to all the different levels

of education, from preschool to superior education levels. Some of them are staff members of the Ministry of Education, others are university professors, school directors, pedagogical coordinators, special education and homeroom teachers, as well as psychologists. Although most of them come from Lima, around 12% come from the provinces.

Following the characteristic of the psycho/pedagogical research on this part of the planet, most of them focus their attention on practical outcomes of their research, such as identification and attention alternatives inside the regular classroom. However, on a macro level, the focus is related to the legal determinants for establishing an acceleration program as an official alternative for those who deserve it.

The impact of these changes in policies and practices towards the education for the gifted, must be monitored to establish new research lineaments on the psychology and education of the gifted in this part of the world.

### Venezuela

In Venezuela there are two programs supervised by governmental organizations that serve gifted and talented children. The first is a branch of the Ministry of Education and is responsible for the whole area of special education. The second is the Galileo Program of the Gran Mariscal de Ayacucho Foundation. The Galileo Program goal is to select and prepare secondary students with outstanding academic performance for continuing advanced studies in foreign universities. The program is based on four stages (preselection, selection course, reinforcement and preparation program, results) which provide a complete psycho/pedagogical assessment through the program.

### Issues and Trends

In South American Spanish spoken countries, where each school establishes its own criteria for identification, ecological validity of the assessment process needs to be taking into account on the selection of an identification process. One of the most important considerations of this process is the establishment of Norms for the general population, which in multicultural and multilingual countries such as the Andean countries is very difficult to achieve. Therefore, in most cases, norms for specific subgroups need to be established.

Each country and school looks for a way to serve the gifted and talented needs. Acceleration, which was an exception in most South America Spanish spoken countries a decade ago, is slowly being considered as a learning alternative for gifted children (Blumen, 2000). Enrichment activities such as, drama, knowledge bowl, chess club, Model UN, debate, drama, music classes, and science-related clubs are available in some of the schools. The students also participate in the various talent searches programs sponsored by universities in

their own countries and in countries of the region, such as science fairs, inventors fairs, maths competitions, among others, and can also compete or get together on international events.

Another common procedure, especially for grades 1–5, is clustering. When students have been identified, they are grouped in the same classroom. The teacher for this class receives special support on the characteristics of the gifted and talented, problems that are often found in a gifted population and an introduction to methods that have been successful with highly capable students. Clustering provides opportunities for the students to be grouped together on some occasions as well as having opportunities to work with non-gifted peers.

Education of the gifted in South America Spanish spoken countries has developed over the last decade. However, this seemed to happen due to isolated efforts. There is a danger that any such major thrust might become a panacea, in which case there is a risk that the needs of the individual would not be met.

Special resources such as universities, research institutions, museums, and other professional organizations are still neglected in educating the gifted and talented children. These institutions have the knowledge, the personnel and the equipment that can cater for gifted and talented students, and give them insight into attractive and challenging areas and methods. These places can also supply mentors for gifted individuals. However, there appear to be only sporadic efforts to use these resources.

The promising sectors are, on the one hand, the schools that belong to foreign communities, such as the German, British, Jewish, and American schools, among others, which have European, Israeli or American influence. And, on the other hand, the science-based industries with research and development departments, and the National Council of Science and Technology who is presenting laws for these industries to adopt youngsters into their research and development departments, and enable them to work with their professionals (CONCYTEC, 1998).

To monitor the impact of these changes in policies and practices on the education for the gifted, ongoing research will be needed as well as a sense of advocacy on behalf of educators and parents.

### **Gifted and Talented Education in Brazil**

Educational concern for the gifted began in Brazil under the influence of a Russian teacher, Helena Antipoff, who arrived in this country in 1929. Before coming to Brazil, Helena Antipoff studied in France and Switzerland, where she conducted studies on intelligence and testing. After arriving in the country, Antipoff continued her research on gifted children, which resulted in several publications in the 1930s and 1940s, calling attention to the need of early identification and educational services for the gifted.

In the beginning of the 1970s, two important facts called attention to the special needs of gifted children. The first was a national general law for education established by the federal government in 1971. This law included an article about special education, stating that “all students, with mental and physical deficiencies, those who are late in their schooling as well as the gifted should receive special treatment, according to the policy at the state level.” The second was the First National Conference on Gifted Children, also in 1971, sponsored by the Ministry of Education. For the first time in Brazil, different aspects of gifted education were broadly discussed among psychologists and educators.

Since then, policies in support of gifted and talented education were reported in several documents from the Federal Government. One of the most important reports was published by the Federal Education Council in 1987. This report was entitled *The Hour of the Gifted*. A Federal Education Council Proposal (Conselho Federal de Educação, 1987) encouraged actions that would be of immediate help in meeting the needs of gifted students. This document outlined the basic principles of special education, criteria, and methods for identifying the gifted, different kinds of programs for the gifted, presented the definition of giftedness adopted in the country, and included several recommendations related to gifted education.

More recently, in 1995, the Special Education Office, from the Ministry of Education, published a report outlining the federal education policies and guidelines for educating the gifted and talented students (Secretaria de Educação Especial, 1995). To reinforce the need for implementing the federal policies at the state level, the Office organized a two-day seminar in 1996 for the staff of the State Special Education Offices from the 26 Brazilian states. During this seminar, guidelines for implementing programs for gifted students were provided, and different models of programs for educating gifted students and provisions for special talents in specific areas of giftedness were discussed.

A new stimulus to the field of gifted education was the III Ibero-American Conference in Brasilia, in 1998. This conference was organized by the Special Education Office, with the support of UNESCO, the Federal District Government, and the Catholic University of Brasilia. Several well-known scholars from the field were invited as keynote speakers, promoting discussions on the importance of nurturing special talents in different areas of giftedness. The State Special Education secretaries attended the conference, at the request of the Ministry of Education. The Brazilian federal government once again called attention to the state educational government to the need of implementing programs for the gifted.

However, as described by Alencar (1986, 1991, 1998), misconceptions about gifted and talented

education are still present among educators and in the community at large. One misconception is the idea that gifted students should always show outstanding performance in all fields; another common belief is that giftedness is a very rare phenomenon. It is also believed that gifted students demonstrate extremely high level of performance and achievement from very early in their lives and that expressions of high ability continue throughout life independent of environmental conditions. Educators also ignore the reality that to be superior in one area does not necessarily imply a superior performance in others. Ambivalence about gifted students prevails in Brazilian society; sometimes the children are perceived with admiration and sometimes with indifference or even hostility.

### *Current Programs*

Before presenting the major Brazilian programs for gifted students, it is important to note that some programs described previously by Alencar and Blumen (1993) were discontinued. This is the case of the program for the gifted and talented sponsored by the National Service of Industry and the program for disadvantaged gifted student sponsored by AVIBRAS Foundation. Other programs, which included different projects and support for talents in specific areas, are facing many difficulties, due to the lack of adequate direction and leadership. In addition to the programs described in this chapter, a few others are being implemented in some private and military schools in Rio de Janeiro, Soã Paulo, and other Brazilian cities. However specific details were not available.

#### *The Gifted College Student: Special Program of Training*

The Special Training Program for gifted college students was initiated in 1979 by the Department of Improvement of Graduate Personnel of the Ministry of Education. This programs aims:

- (1) To provide an excellent academic preparation to those college students who demonstrate an outstanding performance in their academic activities.
- (2) To supply those students with opportunities to further develop higher level thinking abilities and communication abilities.
- (3) To stimulate new pedagogical experiences to improve college education (Dessen, 1994).

Students are selected for this program during their second or third semester at the university. The main criteria for the selection are: high academic achievement, nomination by university professors, and high interest and motivation in carrying out their studies. The selected students receive scholarships and remain in the program throughout their undergraduate program.

The program started with 15 students from two universities. This number increased during this last decade when universities from all parts of the country requested authorization to implement the program in some of their departments. In 1997, 3,556 university students from 317 departments at 59 private and public Brazilian universities participated in the program (CAPES, 1997). In each department, a professor is chosen as the mentor and is responsible for organizing a program of activities and supervising the students. Mentors are selected from the university professors who demonstrate real interest in the program, high academic productivity, and a good relationship with colleagues and students. Every mentor is responsible for 12 students and has to evaluate each of them at the end of each semester.

The program was evaluated in 1997 by a team of scholars (CAPES, 1997). According to the evaluation, 92% of the students across the 317 university departments presented a good performance. Recently, two studies were conducted to analyze the effects of the programs, how the students were perceived by their university teachers and colleagues, and how the program was perceived by non-participating students (Balbachevsky, 1997; Bottura, 1997). A positive impact of the program on the students as well as on their University departments was observed. In addition, teachers and students shared a highly positive image of the participating students.

#### *Project to Orient and Identify Talents: A Program in the Private School System*

Among the programs for the gifted in the private school system, the most well-known is in Objetoivo Education Center in So Paulo. The Center is an educational complex ranging from kindergarten to college, with several schools in different states.

This project was initiated in 1972 and included separate classes for gifted students, followed by the organization of an advanced study program. In 1986, a series of extracurricular courses for the gifted and talented students began with the general purpose of challenging the students' potential and encouraging them to use their own resources in a creative manner and respecting their own pace. The identification procedures are based on the results of intelligence tests and teachers' nominations. Children with exceptional talent in literature and visual arts are also accepted, when indicated by the school psychologist (Cupperino, 1998).

The courses comprise two areas: Technology and humanities. The former aims to help the gifted students become more familiar with technical advances and to find answers for technological problems. The purpose of the humanities course is the exploration of different experiences which in turn would lead to the development of creative and critical thinking, leadership abilities and communication skills. A description of

these courses is provided by Di Genio, Ancona-Lopez & Brandão (1990) and Cuppertino (1998).

Besides the enrichment programs for gifted and talented students, the Project to Orient and Identify Talents (POIT) organizes regular courses on gifted education for educators and psychologists in São Paulo. It also has a counseling service for gifted students and their families. Conferences on giftedness and talent are organized periodically with the most well-known scholars in the field.

#### A Center for Talent Development

In 1993, a Center for the Development of Potential and Talent was founded in Lavras, a city in the state of Minas Gerais. Its main purpose is to provide an enrichment program for the gifted children. Other goals of the Center are:

- (1) To identify the special interests and educational needs of talented children and adolescents and to provide assistance toward meeting these needs.
- (2) To offer support to gifted children in their personal and emotional developmental needs.
- (3) To ensure proper stimulation of youth so as to develop specific abilities and talents (Guenther, 1995, p. 27).

The identification procedure occurs in three stages. At first, elementary school teachers nominate students on the basis of a list of characteristics related to several abilities; nominated students are then examined by the school technical personnel who reevaluate and complete the observations. The students who are selected, as well as their parents, are then interviewed by the facilitator. The final stage occurs during the first year of the child's participation in the enrichment program; during this period, selected students are observed by the facilitator who analyzes the program's benefits for the children.

In 1996, 644 children from different socio-economic classes were enrolled in the enrichment program; these children participate in activities organized in different areas, such as communication and humanities and science and technology. Interest groups are formed with children with defined common interests. Projects are also developed under the supervision of a mentor. Regular encounters, with about 100 children, occur once a month (Guenther, 1997).

#### Public School Programs for the Gifted and Talented

Programs for the gifted and talented have been implemented in the public school system in several states. However, according to Sabatella (in press), the number of students participating in the program is very small. She contacted all the state special education office requesting information about programs for the gifted and concluded that the only public educational

system with a large number of identified students was in the Federal District, where 210 students were participating in special programs in 1997.

The program from the public school system in the Federal District offers gifted students opportunities to optimally develop their potential and talents; to promote their personal social and school adjustment; to expose the students to experiences, materials and information outside the bounds of the regular curriculum; and to expose students to more difficult or more in-depth material (Fonseca, Caixeta, Souza & Cavalcante, 1990).

As described elsewhere (Alencar, 1991), the nomination of the students for this program is made by the teachers who refer students who have demonstrated high intellectual ability, leadership, creativity, academic achievement or talents in the performing and visual arts. The teacher then observes the nominated students for one month, using a checklist to guide these observations. The nominated students fill out a questionnaire about their own interests, hobbies, favorite sports, preference for working individually or in groups, among other topics. Psychological tests, such as Raven's Progressive Matrice Test—General Scale, are also administered.

Educational support for the gifted students occurs in Resource Centers at their own schools and at the Park School. At the Resource Centers, gifted and talented students are exposed to in-depth material on the typical curriculum subjects. At the Park School, students study music, visual arts, ceramics and performing arts once a week; according to their interests, students also participate in one of several clubs (science, flute, photography, foreign language, folklore and others). The Park School also has some learning centers where different enrichment programs are offered.

#### Provisions for Special Talents

A large number of schools for talented students in music, ballet, sports and visual arts are available in many cities of all states. Brazilian middle class children usually have other classes besides those in their regular school. These classes allow the identification of talents and it is the starting point for a professional specialization. There are also several competitions at the local, state and national level in mathematics, chess and science. The oldest and most famous is a project known as Scientists for the Future, described by Alencar (1986), which is a nationwide competition that aims to discover new talents in the field of science and to help those students to continue their studies until the university level.

#### Issues and Trends

Despite the efforts from the Special Education Office, at the Ministry of Education, the majority of the Brazilian states are resistant to the implementation of

special programs for the gifted and talented students. This is mostly explained by the educational problems of the country, as the high rate of illiteracy, limited number of educational institutions, and reduced financial resources for the educational field. Misconceptions about gifted also mask the real needs of this group of students.

Research on giftedness and talent is scarce due to the shortage of experts in the field in Brazil. Most of the research studies have been conducted on creativity and ways to foster creative abilities among the students (Alencar, 1994, 1995a, 1995b; Alencar & Virgolim, 1995; Wechsler, 1995).

There is a lack of programs at the university level to prepare teachers to work with the gifted and talented students; this explains the lack of certification requirements for teachers of the gifted. Courses on giftedness and gifted education have been offered only in a very limited number of Brazilian universities. In general, teachers' preparation for dealing with gifted students is accomplished by special in-service programs; experts from the Brazilian Association for the Gifted have contributed to this training.

We hope that the III Ibero-American Conference on Giftedness in Brasilia, in 1998, was a significant stimulus for discussions among parents, teachers, state government, university staff, and the population in general, about the needs of gifted and talented students, and the importance of generating new programs and implementing different services for these students, whose talents and abilities have been neglected.

### **Gifted and Talented Education in Cuba, North and Central America Spanish Speaking Countries**

Research on giftedness and talent has had a relatively recent development in Cuba, as well as in most of the countries of the region. However, it is necessary to point up that this development has been preceded and stimulated by practical innovative intervention, since education has been a priority and one of the most relevant milestones of the Cuban social project.

Concerns about the education of the gifted and talented were already present in the classics of Cuba's social, pedagogical and scientific thinking. Nevertheless, very few studies on identification and nurturing of giftedness were conducted until the 40s and 50s, where some of them are reported, especially in the University of Havana (Lorenzo, 1996).

Basically, research on outstanding and competent individuals has been approached since 1970 from studies on creativity. González (1985) analyzed the role of moral development and motivational instances such as aspirations, ideals, self-concept, and career motivations, on the emergency of creative performances among high school and college students. Likewise, González (1990), Labarrere (1994), Mitjans (1995), among others, developed related topics concerning the personality of technically creative individuals, the

relations between high abilities and self-regulation, as well as integrative approaches to creativity and its education. The latter could be considered an early expression of Cuban scholar's concerns for giftedness and talent research whereas those notions were not explicitly assumed at the moment.

A very sensitive period for development and reset on giftedness in Cuba began in the eighties. That was the time of the first official projects of research and educational intervention for identifying and fostering intellectual abilities and giftedness in children and adolescents. Examples of very well known projects are ARGOS—Development of Intelligence, Creativity and Talent, PRYCREA—Project for Reflexive Thinking and Creativity, TEDI—Intellectual Development Techniques, and Learning to Learn, inspired on the Venezuelan project Learning to Think and also conducted with children from rural zones of the country.

A meaningful moment for the recognition of this field within Cuban educational and scientific milieus was also the celebration of the I Ibero-American Symposium *Pensar y Crear: Desarrollo de la Inteligencia*, in Havana, 1991. Supported by the Ministry of Education and the Pedagogical University of Havana, the conference allowed for the first time the explicit discussion of the topic and motivated a cooperative search for contextual solutions to the educational issues of giftedness and talent. From 1990, the most important psycho-pedagogical meetings, such as the well known *Pedagogía and Hacia la Educación del Siglo XXI*, are systematically including the exchange of experiences about giftedness, thus giving a new impulse to the social commitments with its investigation and education.

### *Misconceptions about Giftedness*

Social stereotypes and misconceptions about the gifted still remain a gap in the educational progress of this field. A strong prejudice is firmly rooted in the popular and teachers thinking that any differentiated practice with the gifted threaten equity and democratic principles of education. In the scientific domain, concepts like talent, creativity and high abilities have substituted notions like giftedness, intelligence and exceptionally, in order to avoid the elitist and genetic connotation associated to those terms. In general, Cuban society, especially educators, have been more sensitive to the ideal of an education which promotes giftedness and talent within the regular classes, for all the students, according to their potential and without segregation, than to the acceptance of an especial education for the gifted and talented.

Some of the most common misconceptions in this field are the prevalence of cognitive dimensions and academic success when defining giftedness, the belief that gifted individuals do not need special provisions because they "succeed anyway without external support," the idea that their superiority will be shown in all

the contents or activity domains and psychological areas (i.e. advanced emotional development) or, on the contrary, the feeling that gifted and talented always experience emotional troubles and social difficulties (Castellanos, 1997).

#### *An Overview of the Research on Giftedness and Talent in Cuba: Its Impact on Education*

As indicated before, the explicit research on giftedness and talent in Cuba dates back to the late eighties; with very few exceptions, the hallmark of these first works was its commitment to education.

In the Faculty of Educational Sciences of the Pedagogical University of Havana, a research team was established in 1986 to study questions related to giftedness education and provide teachers training on that domain. Some of their tasks concerned the search of identification procedures and techniques suitable to the specific context and mass conditions schools, and the experimentation of instructional strategies aiming at developing higher intellectual skills and student self-management within the regular curriculum of high school and pedagogical careers (Martinez, 1994; Córdova, 1996).

ARGOS project was created in 1986, supported by the Ministry of Education, and with the participation of collaborators from the Pedagogical University of Havana, and educators and researchers from several institutions. The project undertook the task of sensitizing some strategic milieus with the educational needs of the gifted and talented. Its general goals encompassed working with school children (mainly at elementary and secondary level), parents, teachers and directive instances to promote an ambiance of transformation and excellence at school. Definition of giftedness adopted was, to a large extent, inspired by Renzulli's conception of giftedness. Research developed by the project between 1986–1996 focused on topics such as the psycho-pedagogical characterization of Cuban gifted children, the study of their families and its functional dynamic and the diagnostic of teachers' preparation for identifying and nurturing giftedness and talent. Likewise, special programs and strategies for fostering giftedness and talent in the regular classroom were experimentally implemented, with attention to special populations such as disabled and handicapped students, and to their families. As part of the project, Scientific Community PAIDOS was intending to develop scientific abilities and attitudes as well as creative talents among children and their teachers. Unfortunately, ARGOS was discontinued in 1997 whereas a part of its programs is still in progress.

One of the most relevant consequences of this incipient progress in gifted research has been the concern for qualifying teachers and promoting awareness about giftedness and its education. Just to give some examples, the Pedagogical University included two optional courses devoted to the identification of

potential talents, and to the enrichment programs available within the regular curriculum as a part of its Masters in Education program. The higher level career of Primary Education added an academic program, "Attention to individual differences in the regular classroom," which mainly focus on differentiated treatments to stimulate the more able and creative students, and to promote intellectual development. A course about the special needs of the gifted and talented was offered for the first time in 1996 to the teachers and directors of the Vocational High Schools, special centers where a large majority of high able and talented adolescents are attending to.

New research and intervention projects are emerging. That is the case of the Group for Talent Orientation, at the Pedagogical University, and the recent project for Leadership in Talent Youth, of the Center of Psychological and Sociological Research. Educational investigation and experimental practices conducted from schools and universities have proliferated in the last years. As far as can be observed in the proceedings of the psycho-pedagogical congresses and workshops realized, the latter are mostly centered on the development of creative thinking, general and specific domain skills and strategies and metacognitive abilities as well as it moral, affective and social issues. Basic and applied research on the gifted and talented, its identification and education has still a long way to go in Cuba.

#### *State Concerns and Policies Related to Gifted Education*

Since the early years of the sixties, considerable efforts were deployed to provide special attention to talents education whereas this intention was not explicitly stated on official documents and legislation. It remained rather subsumed in a general aspiration of nurturing 'a many-sided personality' with a particular emphasis on integrality (encompassing moral, affective and social dimensions, in addition to the development of intellectual abilities and talents).

At the moment, only a few documents deal with explicit indications for differentiated treatment of the gifted and talented. An official definition of giftedness and talent is still absent. Educational response to the special needs of the gifted and talented is commonly conceived as a part of general strategies of attention to individual differences. However, a suggestive exception is the normative, existing since 1991 in the higher education level which rules a special organization of the instructional processes for individuals categorized as high performance students. They are described as those individuals who:

- (1) Show more rapid pace of assimilation and more advanced learning aptitudes in one or more of the disciplines or content areas, or in scientific research and technical activities.

- (2) Could be identified by their superior performances, creativity and independence in the solution of their academic, technical or research tasks, and have shown to be able to assimilate complementary tasks in their studies project (Reglamento de Trabajo Docente- Metodológico para la Educación Superior. Resolución 269/1991, p. 10).

A differentiated curriculum is recommended for these youth according to their potentialities and individual interests. Several kinds of curricular adaptation, such as compacting courses, the addition, elimination or substitution of academic subjects or topics, should give them more time for scientific and research activities. Mentorships, provided by teachers and outstanding professionals and researchers, is stipulated as a part of the special provisions regulated in the law.

Unfortunately, the existence of these sort of documents is not yet generalized for the rest of the levels and types of instruction, so that most of the efforts done to adapt school process to the gifted and talented educational characteristics are originated by the teachers own initiative and school administration with more or less success.

#### *Provisions for the Gifted and Talented in Cuba*

Special provisions for the gifted and talented in Cuba are carried out in different ways. It is important to point out that Cuban education is totally public. In the framework of the formal school (National System of Education), attention to special talents has been a historical concern.

Vocational High Schools for Sciences and for Pedagogical Sciences, Schools for Sports Initiation, Vocational Schools for Arts, among others, constitute special pre-university level centers; the students are mainly selected on the basis of specific aptitudes and performances. In addition to a general curriculum, they can benefit from a flexible cycle of specialization and complementary (enriched) programs aiming at developing talents, vocation and careers orientation within specific domains. Focus on investigation work, and the search of concrete and applicable solutions to the regional problems are important features of the pedagogical conception of those schools, particularly in High Schools for Sciences. There, intervention for the giftedness can adopt the way of instructional variants of enrichment and subject matter acceleration, advanced thinking skills training in the classroom and mentorship.

Likewise, organizations such as Children Innovators's Movement, Interests Centers like regional and international Competitions and school Olympics are conceived as stimulus for the gifted and talented development.

On the other hand, attention to special talents is provided by specific institutions in each community. That is the case of the Culture Community Centers, the

Young Computational Clubs, the Centers for Creative Youth (Visual Arts), the Centers for the Young Musicians, the museums and sports-centers, among others. Courses, activities and programs are organized to promote apprenticeships as well as development of interests and creative productivity in children, adolescents and youth, who may freely attend them.

In 1997, a specialized Chair for the Development of Intelligence, Creativity and Talent was initiated, sponsored by the Pedagogical University of Havana, attending to promote necessary research and intervention in the area, social awareness and support, and to create the basis for scientific understandings and exchanges between Cuban investigators and practitioners. Also, the need for a greater communication with the international scientific community is recognized.

#### **Programs and Practices for the Education of the Gifted and Talented in Central America**

The precarious situations of the countries from the Central region of America, in the economic, social and educational aspects, determines to a large extent the fact that financial resources and efforts have to necessarily be spent on the projects devoted to more elementary goals such as, for example, to increase schooling attendance.

In *Puerto Rico*, we know about the existence of the Organización para el Fomento del Desarrollo del Pensamiento, directed by A. Villarini (Zilberstein, 1996), which develops a pedagogy to fostering intellectual abilities and giftedness within the curricular contents.

In the Institute of Psychological Research of the University of Costa Rica, research on giftedness is focused on intellectual competence (intelligence) and creativity, with special emphasis in developing identification and diagnosis procedures for students selection, as well as conceptual frames to understand those processes (Tapia & Molina, 1998).

In *Guatemala*, although experimental research on highly capable children has not been carried out, supporting programs for highly capable students have been established, as the Asociación Pro Alumno Talentoso y Superdotado, which aims to identify and to promote the talents of the gifted and talented. The Universidad del Valle, through its Programa de Orientación y Becas para Estudios Superiores assesses giftedness through batteries of Aptitude Tests, and scholarships for university studies are available for the high capable students identified. In addition to this, in 1992, a program to identify highly capable students was initiated at the Universidad del Valle. in order to provide them scholarships and other economic support for continuing university studies (Alencar & Blumen, 1993).

*Mexico*, a Spanish speaking country located in North America has developed several proposals that attempt to meet the needs of the gifted children in

regular classrooms, based on the Renzulli (1978) model, in an effort to cope with the conditions of the gifted children attending regular public elementary schools, that followed the educational philosophy that the General Direction of Special Education stated.

The Mexican proposal considers five fundamental aspects: (a) a continuous sensitivity program on the needs of the gifted children applied to the whole school community, (b) activities to identify gifted children in the classroom, (c) general and specific thinking skills activities to the school population, (d) research and creative productive activities to all the students of special populations, and (e) permanent identification programs from a broad conception of the human being, which considers multiple identification criteria as well as direct observation in every student activities. The main goal is to identify and to develop the creative and productive potential of all children as well as to promote their academic achievement.

In 1982, the first public school for Mexican gifted children was established in Puebla, a city located 100 km South of Mexico City. The school began with 143 children having an IQ higher than 120, coming from 23 public schools, 10 federal schools, and 13 private schools.

Later, the *Centro de Desarrollo del Intelecto* (Center for the Development of the Intellect), a private organisation that served children of middle-high socio-economic level was also established in Puebla, to promote favourable conditions for the development of their gifts and talents, and to provide psychological and pedagogical support for skills that were not attended to in the traditional school system (Arroyo, 1989).

Also in Mexico City, there has been a proposal that attempted to meet the conditions of the public primary schools as well as the educational philosophy followed by the Head Office of Special Education. The main objective of the proposal was to identify and promote the creative and productive potential of children and to encourage their academic performance.

During the 1987–88 school year, a program for gifted and talented children was begun in 38 primary schools in Mexico City. A variety of identification and enrichment programs was developed. One of the initial results was that 5430 children in regular schools and 993 children in special education schools benefited from this program.

In June 1988, the works of 45 children was exhibited to the public; and later, on July 30 and 31, the First International Seminar 'Meeting the Needs of Gifted Children' was held in Guadalajara, Jalisco, Mexico. The event was organised by the Psychology Department of Guadalajara University and the Special Education Department of the Mexican State Education Office, and provided an opportunity to share and to exchange experiences related to gifted children and their educational needs and problems. Some of the problems faced by Mexican researchers (Cortes &

Schwanke, 1988), such as administrative difficulties and a lack of physical conditions, are very common in Latin American countries.

### Issues and Perspectives

This chapter addressed gifted and talented education in Latin American countries. It pointed out the huge differences in services available for nurturing the gifted students among the countries in this part of the world. While in some of them, as in Brazil, educational policies related to gifted education were proposed more than 25 years ago, there are countries where the first programs are being initiated as experimental proposals, and others with no educational provisions for attending the gifted and talented students.

An analysis of the current situation of gifted education in Latin America also indicates that several programs which were implemented in different countries were discontinued. This was due to the lack of financial support as well as to stereotypes, prejudices and misconceptions about the gifted students. On the other hand, much progress was observed in Peru and Cuba in this last decade, where several initiatives in favor of the gifted and the talented have occurred.

In order to enable the gifted students to develop their abilities to the full, several initiatives are urgently required. One of them is the need for disseminating information about giftedness among school staff, teachers and parents, in order to make them more aware of the cognitive, social and emotional needs of these students.

It is specially important to prepare teachers to become more effective in working with the gifted. It is also necessary to make them aware that by ignoring the gifted, society loses many talents and leaders who could make a significant contribution to the solution of the problems of the country and to the progress that the society desires.

More research needs to be carried out in this area, to gain a better knowledge about the gifted and the talented children that belong to different socioeconomic levels in Latin American countries. The socioeconomic level should be taken into account in future studies, because it is very probable that more similarities would be found between children of similar socioeconomic status among the Latin American countries, than between the different socioeconomic levels in the same country.

It is also important that college and universities include gifted and talented education in their curriculum, in order to prepare teachers to identify and nurture the gifted and talented children.

Finally it is imperative that the educational authorities in Latin American countries acknowledge several issues identified previously in the chapter and that they respond by contributing to the implementation of educational conditions favorable to the gifted and talented development.

# A Multidimensional Framework for Synthesizing Disparate Issues in Identifying, Selecting, and Serving Gifted Children

Robert J. Sternberg<sup>1</sup> and Rena F. Subotnik<sup>2</sup>

## The Case of Justine Handley

Justine Handley, 8 years old, is being considered for selection into the gifted program at Cotswold Primary School. She has been recommended by her classroom teacher, but so have 17 other students, and there are only 10 open slots in the program. Right now the selection committee is deciding whether to admit Justine. They have available the following information:

- (1) Full-scale IQ: 99th percentile
- (2) Full-scale creativity score: 85th percentile
- (3) Achievement tests: Verbal—98th percentile; Maths—85th percentile
- (4) Teacher evaluation of motivation: 90th percentile (the committee's evaluation of her current teacher's recommendation)
- (5) Peer nomination: 3 of her current classmates out of 25 identified her as the most able student in the class.

Should the committee admit Justine into the gifted program?

A discussion ensues among the five committee members, yet the deliberations are not achieving consensus. Consider their views.

Andrea Erickson, the principal, enthusiastically supports Justine's admission based on her scoring in the 99th percentile on an individually-administered IQ test. Andrea would not consider someone acceptable with an IQ score below the 95th percentile, and Justine is well above this level. Andrea points out that IQ has been shown to be a reliable measure and a valid predictor of success in rigorous academic programs like the one at Cotswold School.

Francesca Priestly's reasoning is somewhat different. As a gifted education consultant, Francesca believes that there are many different ways to demonstrate giftedness besides IQ, and that children selected for the Cotswold program can be identified as gifted by meeting any one of the criteria. The Cotswold program offers challenging individual and group activities in reading, writing, mathematics, science, foreign language, arts, music, and physical education. There are thus many ways to succeed in the program. Francesca believes that Justine qualifies for the program on the basis of her being in the 98th percentile or above with respect to either her IQ score *or* her verbal achievement score.

Jerry Baumgartner, a psychologist, is reluctant to admit Justine simply on the basis of IQ. He has seen that many students are able to remember and analyze other people's ideas without being able to come up with any good ideas of their own. According to Jerry, creativity is just as important as IQ. Therefore, to be identified as gifted, a student should attain scores in the 95th percentile or above on *both* IQ and measured creativity. It is not clear to Jerry that Justine could meet the demands of the Cotswold gifted program, which require students to produce creative work on a regular basis. He views Justine as sufficiently intelligent but as insufficiently creative for admission to the gifted program.

Curtis Hill, a teacher, believes that strengths in certain areas can compensate for weaknesses in other areas. In fact, the Cotswold faculty has been trained to assist students in using their special aptitudes to offset their academic or social weaknesses. Therefore he believes that the best policy is to average scores across criterion measures and to select those students with the highest average score. In this way, Justine's higher scores in IQ and verbal achievement can compensate for her relatively lower scores in creativity, maths achievement, and the estimation of her peers.

Another teacher, Ronnie Shabad, believes that what should matter in making selection decisions is how far

<sup>1</sup> Yale University, USA.

<sup>2</sup> Center for Gifted Education Policy, American Psychological Foundation, USA.

you have come rather than where you are at a given point in time. She points out that although Justine’s test scores are generally quite high, Justine’s parents are well educated, economically successful, and have been actively involved in Justine’s education. For Ronnie, a teacher’s recommendation is key, and Justine’s teacher-rated motivation score is not consistent with a picture of someone who is prepared to commit herself to the effort expected of students in the Cotswold gifted program. She points out that other candidates with similar test scores have made better use of the opportunities provided them. In fact, some of them have achieved at a very high level coming from homes with less well-educated or economically successful parents.

The five committee members are all committed to an excellent gifted program and to ensuring that the children selected for the program can optimally benefit from the experience. But the committee members differ in their preferred approaches to combining the criterion information available. The difference in approaches leads them to different decisions regarding Justine and other candidates.

In this chapter, we provide a unified framework for understanding disparate issues elucidated in this handbook that are often viewed as unrelated or only weakly related to each other. The chapter is divided into three major parts. The first part presents a multidimensional model and describes four approaches to the identification and selection of candidates for gifted programs. The second part deals with the application of the multidimensional model to challenges confronting gifted education, as described in this handbook. The third part draws some conclusions.

**Four Approaches to Identification and Selection of Candidates for Gifted Programs**

*Static Models*

Static models of identification and selection assess performance at a given point in time. Conventional intelligence tests, creativity tests, achievement tests, and peer nominations are all examples of static assessments.

The five approaches promoted by the various members of the Cotswold committee represent an array of mathematical combination rules for a given set of selection criteria. Approaches are not ‘right’ or ‘wrong’, but rather, appropriate to given goals set for identification, instruction, and assessment of performance. These goals, in turn, may vary, depending on the values they reflect. Because of limited resources, identification tied to theory can be unwittingly transformed into selection based on available space in programs (Subotnik & Coleman, 1996; Louis, Subotnik, Breland & Lewis, 2000). Thus decisions on who will be served take into consideration cultural and community resources, which vary from place to place.

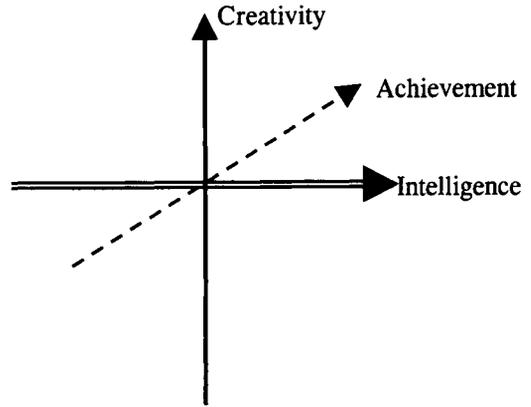

Figure 1. Example of a Static Model

Each of the approaches personified by Cotswold committee members sets a different combination rule for dimensions of a multidimensional space of giftedness and talents. In this space, certain people are identified as being in ‘regions’ that entitle them to be labeled as gifted and to consequently receive services; other people are not. For example, IQ might be conceived of as one dimension of the space; creativity test scores as another; achievement test scores as one or more others; and motivation and peer nominations as still another (see Fig. 1). The regions of the multidimensional space that represent ‘giftedness’ differ for each different approach.

*Single Cutoff: Targeted Criterion*

Andrea Erickson supports a single-cutoff, targeted criterion approach (see Fig. 2). In this approach, one considers only a pre-specified single piece of information, such as an IQ score, and makes a decision based on whether an individual’s score is above a certain predetermined threshold (or cutoff). The rest of the data collected for each applicant would be used only for curriculum planning if the child is admitted to the program.

Andrea happened to use IQ in her decision making, but the model refers to any single targeted decision criterion applied to a pool of potentially eligible candidates. The cut-off might refer to IQ, maths SAT, a creativity test score, grade-point average, or any other single piece of data collected for each individual. Note that the single criterion can be more nearly domain general, such as a measure of IQ, or more nearly domain specific, such as maths SAT.

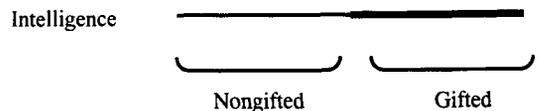

Figure 2. Example of a Single Cutoff: Targeted Criterion

The assumption underlying this model is that, although various criteria may be informative, only one is definitive and hence should be decisive in making selection decisions. The decision to use one targeted criterion over others may be because performance on this criterion has been shown to be highly predictive of performance in a particular gifted program or similar ones, or it may be a philosophical decision based on a unidimensional conception of giftedness (e.g. giftedness as determined by IQ). For this model, the bottom line is that a score above a certain cutoff on the targeted criterion is necessary and sufficient for admission to a program.

There are several potential advantages to the single-cutoff, targeted-criterion approach. For one thing, it is uncomplicated, especially for parents and the public. A criterion is announced in advance, and children must either make the designated cut-off or they do not get in. Also, adding selection criteria can produce diminishing returns. In other words, the incremental predictive value of additional criteria may not justify the addition of these criteria. Finally, using a single criterion tends to be quicker and cheaper, and involves less deliberation than is the case for multiple criteria.

There are also potential disadvantages to this approach. The single-cutoff, targeted criterion approach may not do justice to the full richness of the giftedness construct. Whether additional criteria contribute to prediction of success in a gifted program is an empirical question, and unless one starts off with these additional criteria, one may never find out whether they would have been useful. Given the investment that must go into the construction of a gifted program, the approach may be too simplistic for making defensible high stakes decisions about candidate selection.

*Single Cutoff: Flexible Criterion*

Francesca Priestly supports a single-cutoff, flexible-criterion approach (see Fig. 3). In this approach, like the previous one, the decision-makers consider only a single piece of information, but they are flexible as to which piece that information might be. For one individual, it may be an IQ score, for another, it may be a motivational rating. The key is to find the attribute that represents the individuals' greatest decision-relevant strength, and to use that attribute in making a

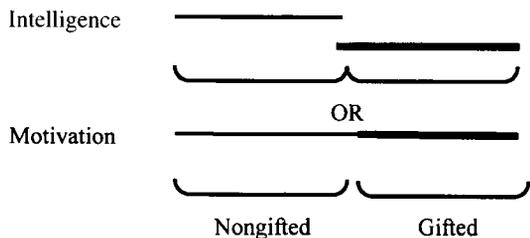

Figure 3. Example of a Single Cutoff: Flexible Criterion

decision. The decision is based on whether an individual's score is above a certain threshold (or cutoff) for the criterion relevant to that individual.

This approach may be viewed as a disjunctive generalization of the first approach. In the single-cutoff, targeted-criterion approach, one index is chosen in advance as decisive. In the single-cutoff, flexible-criterion approach, surpassing the cutoff on any one of a set of criteria is sufficient for entry into the gifted program.

Sometimes cutoffs are used negatively; students are rejected if any one of their scores falls below a certain point. Positive and negative cutoffs may be used together, whereby selection entails a candidate's being above a high threshold on at least one criterion but not below a low threshold on any other criteria.

The single-cutoff, flexible-criterion approach is attractive for several reasons. For one thing, this approach recognizes the multiplicity of gifts and talents (see, e.g. Gardner, 1983; Sternberg, 1985, 1997). Although people may prefer different models or theories of giftedness, virtually all people recognize that gifts and talents are, in fact, multiple. This approach therefore promotes greater diversity among those selected for admission to a gifted program, and adding a negative cutoff can ensure that there is a basic level of competence that exists among all students. The single-cutoff, flexible-criterion approach may also encourage a certain kind of synergism that arises when people's strengths are complementary rather than identical. For example, a group project to design a new form of transportation might require the talents of people who excel in creativity, writing, social skills, and problem solving (each reflected in various admission criteria for the Cotswold program).

The single-cutoff, flexible-criterion approach also has its drawbacks. First, it may be difficult to construct a curriculum that does justice to the broad range of gifts and talents that can be identified with this approach. The diversity of skills in the classroom may require more individualization of instruction than the teacher is able to provide. In addition, the number of potential talent domains and hence selection criteria a program might use is extremely large. It can become difficult—both philosophically and politically – to decide which talents or gifts are potentially relevant for decision making. Third, this approach is potentially costly and time-consuming if too many criteria are taken into account.

*Multiple Cutoff*

Jerry Baumgartner, in the case study above, supports a multiple-cutoff approach (see Fig. 4). In this approach, one considers a set of pre-specified pieces of information, such as an IQ score, a creativity-test score, and an achievement-test score, and makes a decision based on whether an individual's scores are above certain predetermined thresholds (or cutoffs) on all of the

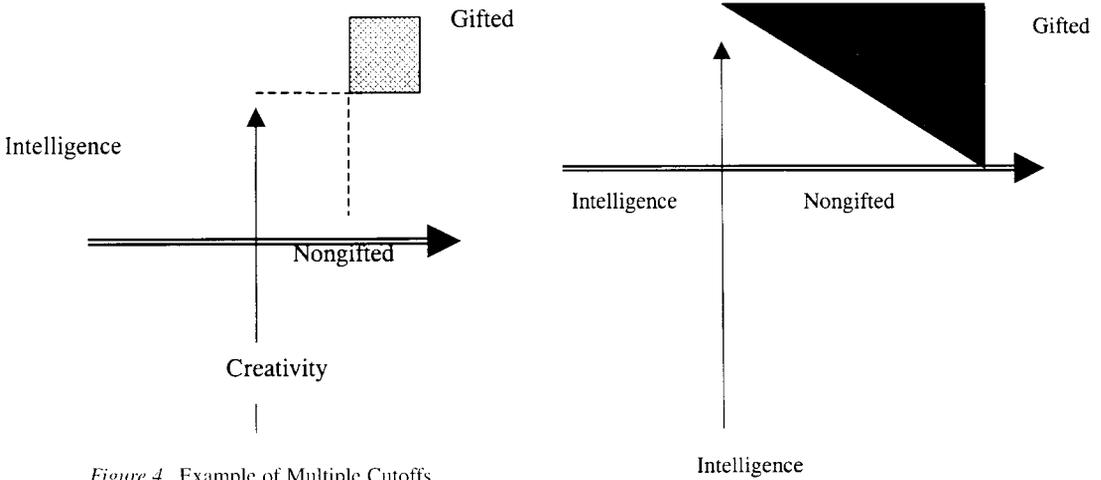

Figure 4. Example of Multiple Cutoffs

measures. Jerry, for example, believes that both IQ and creativity-test score should be incorporated into the selection procedure for admission into the Cotswold gifted program (see also Sternberg & Lubart, 1995).

This approach assumes that giftedness is best described conjunctively—as someone’s scoring above a pre-specified threshold on each of a set of measures, all of which in combination are believed to predict success. In this approach, therefore, each above-cutoff score is necessary but individually not sufficient for the student to be selected for the program.

By implication, only a relatively limited number of criteria can be used, and cutoffs have to be set at a reasonable level so that a sufficient number of people can be identified as gifted. Consider three advantages of this approach. First, this approach takes into account the interactive nature of gifts and talents by having multiple cutoffs, for example, on tests of IQ, creativity, and achievement. Second, this approach ensures that selected students are at a relatively high level on *all* of the skills deemed to be important for success in the program. Consequently, teachers can prepare instruction without worrying that individual students’ weaknesses will undermine the effectiveness of that instruction. Third, this approach is relatively cost- and time-efficient if one limits the number of criteria that are used in decision-making.

As with all the other approaches discussed thus far, there are also disadvantages. Individuals whose gifts or talents are exceedingly high in one area but non-exceptional in one or more other areas may be excluded. For example, in a system that requires above-threshold scores on IQ and achievement tests, someone with an exceptionally high IQ or an exceptionally high achievement score may be rejected because his or her other score is merely high, but not exceptional. Because of the need to set reasonable cutoff levels it would be possible to identify as gifted an individual

who shows a high level of skill in several areas, but perhaps an extraordinary level of skill in none of them. Finally, use of this approach may require a relatively substantial investment of time and other resources in the identification procedure with little room to maneuver in the process except in determining cutoffs.

*Averaging*

Curtis Hill supports an averaging approach (see Fig. 5). In this approach, scores on each of multiple criteria are converted to a common unit (such as a standard score), and then averaged. Because the various criteria are not necessarily viewed as being of equal predictive validity, they may be weighted to reflect their perceived importance. For example, Justine’s percentile scores might all be converted to standard (z) scores, weighted, and then assigned an average value as a single index of her suitability for selection into the gifted program.

This approach assumes that giftedness is multi-dimensional and that higher scores in some dimensions of giftedness can compensate for lower scores in other dimensions. As typically used, it also assumes linear weighting of the variables with no interactions. Linearity implies that a score difference of a certain number of points is consistent at any two points along a continuum (e.g. the difference between IQs of 120 and 130 is identical to the difference between IQs of 150 and 160). *No interactions* means that, for example, the relation between IQ and creativity would be the same at all points along the continua of both.

A main positive feature of this approach is the fact that it uses all of the available (linear) information, whereas in other models, information is essentially wasted for the purposes of identification. The approach guarantees that no candidate who is selected is fairly weak in several dimensions or extremely weak in any of them. In other words, several fairly low scores or

one extremely low score is likely to take the candidate out of consideration. This fact ensures that teachers will have to do little or no remediation with their gifted students. Also, employment of this approach is likely to lead to diversity among selected students, because the criteria along which people score well are likely to differ.

This approach also has weaknesses. First, some people believe that giftedness is a construct that should deal with true exceptionalities, not averages. Second, the sheer diversity in number and kinds of talent profiles may challenge teachers in ways for which they are not prepared. Third, just one extremely low score may knock someone out of the running for admission to a gifted program, even if the low level of functioning represented by this score would not necessarily be problematical for successful performance in the program, e.g. not being nominated by peers from a non-selective environment. Finally, it may be difficult to find criteria for which there are no interactions (cf. literature on correlation between IQ and creativity test scores in Sternberg & O'Hara, 1999).

#### *Dynamic Models*

Dynamic models involve assessment of estimated change over time (see Fig. 6) (Grigorenko & Sternberg, 1998; Kanevsky, this handbook), taking into account the context in which the assessment takes place. Before comparing the children to each other, the children are compared to themselves at two or more hypothesized points in time. The idea is to determine how far a child has come and thereby predict how far the child can go. Children who have come further, it is assumed, are those who take better advantage of the opportunities they are given.

For example, Ronnie Shabad has pointed out that, although Justine's profile is a good one, it does not indicate that she took maximal advantage of opportunities. Other students with comparable profiles may have been reared in families without the Handley's eco-

nomnic wherewithal to be actively involved in their child's schooling. Or they may have grown up in households with poorly educated parents.

Each of the approaches described above can be operationalized in a dynamic way. For the single-cutoff, target-criterion approach, one would look at growth in the single criterion, considering, for example, not only current knowledge base, but also, early opportunities for acquiring this knowledge base. For the single-cutoff, flexible-criteria approach, one would look at maximal growth in any one of the criteria. For the multiple-cutoff approach, one would look at a minimal required level of growth in each of the criteria; and for the averaging approach, one would average growth across the multiple criteria.

The dynamic model has one overarching advantage. Children start at different metaphorical points of origin and so may have relatively longer or shorter routes to traverse to meet preset identification or selection criteria. Consequently, this approach promotes diversity with respect to the origins and family backgrounds of the children likely to be selected for a given gifted program.

The dynamic model also has potential disadvantages. It is difficult to operationalize concepts such as 'point of origin', 'environmental advantage', or 'family background'. What measures does one use to operationalize 'environmental advantage'? For example, two children may come from environments that are equally disadvantaged financially, but in one environment, the children were strongly encouraged to engage themselves in their schoolwork, whereas in the other environment, they were not (Olszewski, Kulieke & Buescher, 1987). Most important for the discussion at hand, one can come a long way but still not excel. For a particular child from a particularly difficult environment, reaching an average level of performance on several measures may be impressive, but does that level of performance entitle the child to be labeled as gifted (Noble, Subotnik & Arnold, 1999)?

Up to this point, we have been describing various models and approaches to the identification and selection of the gifted. How do these models help us synthesize some of the disparate issues in selecting, identifying, and serving gifted children?

#### **Application of the Multidimensional Model**

Many pressing issues confront gifted education today. These issues not only affect the research agenda of the field, but also the day-to-day operations of gifted programs, like the one at Cotswold School.

#### *The Role of Gatekeepers*

Gatekeepers operate at two different levels. At one level, they identify and select gifted students. In terms of the multidimensional model, they: (a) select which dimensions in the multidimensional space they view as relevant to identification and selection, and (b) form a

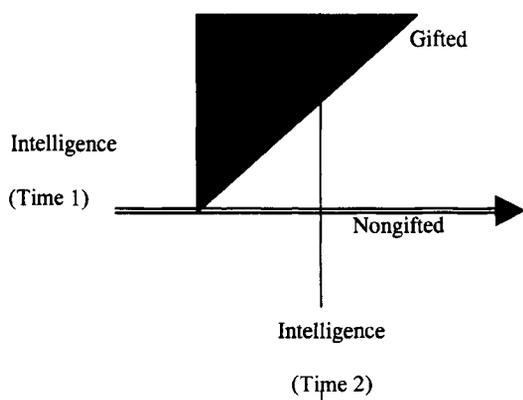

Figure 6. Example of a Dynamic Model

combination rule (what we have called an *approach*) for combining the information contained in multiple dimensions. For example, they might select IQ and creativity score as two dimensions, and then use a multiple-cutoff rule as their approach for combining information from those two dimensions. At a second level, they determine the criteria by which people advance in their education or in their field of endeavor (Feldman, Csikszentmihalyi & Gardner, 1994). For example, they decide which areas of research will be funded and which ones will not be, or which kinds of art works will be displayed and which kinds will not be. In terms of the multidimensional model, they judge the creations that emanate from the hypothetical constructs underlying the dimensions (e.g. creativity is the hypothetical construct underlying one or more scores on a test of creativity).

### *The Cultural Context of Giftedness*

The cultural context in which giftedness is judged affects the dimensions and combination rule that are selected. Thus, people who excel on a particular dimension, such as hunting prowess, may be viewed as gifted in one culture but as undistinguished in another (Bourdieu, 1977; DiMaggio, 1982; Gardner, 1983; Sternberg, 1985; Bronfenbrenner, 1993; Meyer, 1994) because hunting is peripheral to the central enterprises of the culture. A highly precocious and competent reader might be valued in one culture, but hardly recognized in non-literate cultures.

When people move from one culture to another, they may find themselves either newly labeled or no longer labeled as gifted. The difference may be due to the dimensions that are valued or of the qualifying level of performance on those dimensions. For example, some Asian students whose mathematics performance might be above average but undistinguished in their own countries might look gifted in the United States, where the levels of mathematics achievement are, on average, lower.

In extreme cases, excellence in the dimensions that are valued in one culture or one time may lead to one's execution in another culture or time (Simonton, 1994). For example, in some countries in some periods of time, people perceived to be intellectuals have been viewed as highly dangerous. A charismatic leader who is gifted during an epoch of dictatorship may find him or herself in line to be executed when the culture or mores of the country change.

People whose cultures or subcultures are distant from the mainstream may find themselves having developed skills that are valued among their own group of people but not among the people in the cultural mainstream (Scott, Peron, Urbano, Hogan & Gold, 1992; Ford, 1996; Subotnik & LeBlanc, 2001). It may be quite a bit more difficult for people from distinct cultures to be labeled as gifted by the mainstream simply because they have so far, metaphorically, to

travel to acquire the skills that the mainstream values (Olszewski-Kubilius, Grant & Seibert, 1993). In such cases, the dynamic model may be useful in showing just how far they have come (Feuerstein, 1973; Wright & Borland, 1993; Borland & Wright, 1994).

### *Domain Generality versus Domain Specificity of Giftedness*

Dimensions in the multidimensional space differ in terms of the degree to which they represent general vs. domain-specific characteristics. For example, many psychologists view IQ as general (although not completely) intelligence because the aspects of intelligence it measures apply across many domains of endeavor. Musical-composition skills, in contrast, would be viewed as more domain specific, because these skills apply in fewer domains of endeavor. Because humans tend to specialize over time, identification of the gifted often focuses on more general abilities when applied to children and young adolescents, and more domain-specific abilities and skills when applied to older adolescents and adults (Feldman, 1986; Subotnik & Olszewski-Kubilius, 1997). Indeed, with few exceptions, it is harder to measure domain-specific expertise in younger than in older individuals.

Different domains have different trajectories. A highly successful career in violin performance or ballet is dependent on early investment in instruction and practice (Feldman, 1986). In contrast, most psychologists, do not decide on their domain of specialization until they reach the high school or university level.

### *Who Gets Served?*

Who gets served in gifted programs depends on the dimensions of the multidimensional space that are valued and on how these dimensions are combined. It also depends on whether one uses a static or a dynamic model of assessment. In the former model, those who are served will be those who have the highest value(s) on the relevant dimension(s) at a given point. In the latter model, those who are served will be those who have traveled the longest distance from some perceived starting point to where they are now.

Another factor that might be taken into account is the level or kind of service that a child will receive if he or she is not accepted into a program for the gifted. Some families will arrange for their children to receive services that are almost comparable, whereas others may be thrown into educational environments that are stultifying and even alienating.

### *How Do the Gifted Get Served?*

Ideally, a gifted program like the one at the Cotswold School should have parallel dimensions for identification, selection, curriculum design, and assessment of performance. For example, if the program selects students on the basis of IQ and creativity-test scores, then the underlying abilities relevant to performance on

each should apply to performance in the gifted program.

Many domains in which giftedness is assessed make a distinction between performance-related aspects and creative-productivity related aspects. The way students are identified, taught, and assessed may differ depending on which aspect is to be emphasized. For example, both musical performers and composers will study music theory, but the emphasis will be different. Performers will employ theory to interpret what they play, while composers need theory to help them structure and improvise effectively.

#### *Will Those Who Get Served become Gifted Adults?*

Many children who are identified as gifted children will not be viewed so when they become adults, just as many adults who are viewed as gifted will not have been identified as gifted when they were young. There are a number of reasons for this discrepancy. First, the dimensions used to assess giftedness during childhood and adulthood may differ (Subotnik & Olszewski-Kubilius, 1997). For example, scoring brilliantly on reading and mathematics achievement tests may be essential and sufficient for success in school but not for success in many jobs. Second, as noted earlier, domain-specific dimensions typically become more important with age. For example, advanced interpretational skills in music may not be easy to assess until an individual first has acquired a considerable level of technique. Third, assessment of giftedness among children tends to stress potentialities, whereas assessment of giftedness among adults tends to be based on assessed accomplishments (Subotnik & Arnold, 1999).

There are at least two points of view regarding discrepancies in childhood vs. adult giftedness. One is that we are mistaken in whom we identify as gifted in childhood, and that we need to pay more attention to the dimensions that will be relevant to career performance later on. In science, for example, the ability to learn the basic material may be important earlier on, but the ability to generate interesting questions will become more important later on. Perhaps we need to expend more effort promoting question-generating ability among young people. From another perspective, giftedness is a different construct for children than for adults, and children should be served on the basis of the dimensions that are relevant for childhood giftedness, regardless of whether these dimensions will be relevant to occupational success later on.

#### **Conclusion**

In this chapter, we have presented a multidimensional model for understanding the identification and selection of the gifted. We have described two different ways of using the model through static and dynamic assessment. We have also described four different approaches that fall under the model: the single-cutoff, targeted-criterion approach; the single-cutoff, flexible-

criterion approach; the multiple-cutoff approach; and the averaging approach. We have also discussed several issues that can be informed by our model.

We believe that a unified model provides an umbrella under which a large number of issues can be covered. More specifically, it helps prevent different activities from operating at cross-purposes to one another, as when one set of dimensions matters for selection into a program but a different set of dimensions matters for success in the same program. A unified model also clarifies how the dimensions that are valued in childhood giftedness can be either the same as or different from those dimensions that contribute to giftedness in adults.

It is certainly possible that we have tried to be too all-encompassing, missing the fine grain thinking taken into account by gifted-education specialists. However, we believe the advantages outweigh the disadvantages. This handbook is so rich with information and theory that readers may find it helpful to view the field through such a lens. Alternatively, we look forward to the handbook serving as a catalyst to our readers in their own model development.

# The Study of Giftedness: Reflections on Where We Are and Where We Are Going

Franz J. Mönks<sup>1</sup>, Kurt A. Heller<sup>2</sup> and A. Harry Passow<sup>†</sup>

## Introduction

At the entrance to the third millenium, people and groups concerned with the nature and nurture of giftedness and talent—educators, policy-makers, researchers, the public—find that, despite a large and growing knowledge base, issues concerning the education and development of the gifted continue to be discussed and debated. It might even be said that, as in other fields, the more that is known, the more issues are raised and controversies are fueled. Issues concerning the gifted field have never been confined to a small group of children and youth identified as ‘gifted or talented’ but have an impact on the whole of education. For example, the issues surrounding questions of *excellence and equity* affect all educational decisions, not just provisions made for the gifted. Despite a century of programming for the gifted, such efforts are still debated as to whether or not they are elitist, undemocratic and even necessary (cf. Henry, 1994; Herrnstein & Murray, 1994; Jacoby & Glauberman, 1995; Mönks, 1996). Towards the end of the 20th century ‘cluster grouping’, one kind of ability grouping, had once again become the focus of policy debates with research cited to support both sides of the controversy (Gentry et al., 1999). These are just a few examples of the perennial issues which are unresolved despite the accumulation of research, theory and experience over the past century. In fact, it is likely that they will never be fully resolved; supporters of gifted education will only find a more solid basis for their positions with the growing base of research and theory.

In the first report on his longitudinal study, Terman (1925) suggested that, as more is learned about giftedness and how gifted children should be educated, we will learn more about increasing the talent reservoir:

When the sources of our intellectual talent have been determined, it is conceivable that means may be found which would increase our supply. When the physical, mental and character traits of gifted children are better understood it will be possible to set about their education with better hope of success . . . In the gifted child, Nature has moved far back the usual limits of educability, but the realms thus thrown open to the educator are still *terra incognita*. It is time to move forward, explore and consolidate (pp. 16–17).

The German psychologist Stern emphasized in 1916:

It is strange that until now there exist thorough diagnostic processes only for the children for whom we have concern because of some handicap but not for the children of hope (p. 114). For 2% of the highly gifted and another 10% of the gifted elementary school children we need provisions for appropriate nurturing (p. 109).

To reflect on research and education of the gifted at the beginning of the new century requires a look at the issues and problems in the field—many of which are perennial—which will shape the future of talent development.

## The Beginnings of Study of the Gifted

Modern giftedness research has a long past but a short history. Confucius in China and Plato in Greece (in *politeia*, VI) discussed ‘heavenly’ (gifted) children. They attempted not only to explain giftedness or high ability theoretically, but also made practical suggestions for the identification and selection of the gifted and for nurturing them in society. In this way giftedness or talent was considered as a national resource, to be encouraged and multiplied for the good of the community. It is interesting to note that both East

<sup>1</sup> University of Nijmegen, The Netherlands.

<sup>2</sup> University of Munich, Germany.

Asian and Classical European traditions adopted largely identical interpretations of giftedness and talent, which were considered to be gifts from nature, in the form of exceptional cognitive abilities (perception, thinking, learning and memory).

The close relationship of giftedness to the concept of intelligence is shown etymologically not only in the Chinese attributes 'Tsung' and 'Ming' (exceptional sight and hearing) but also both in the Latin meaning of 'intellect' in the philosophy of Aristotle and in the writings of the later English Sensualists (e.g. John Locke, 1632–1704). This European attitude or hypothesis was expressed in the assumption: *Nihil est in intellectu, quod non prius fuerit in sensu* (the intellect contains nothing that did not come to it through the senses). This intellectual conception of giftedness or talent was probably first broadened to include motivational and environmental components by Terman (1954). In the New Testament parable (Matthew 25, 28) Jesus spoke of the talents entrusted to mankind. The term 'talent' (*talanton* in Greek, *talentum* in Latin) was derived originally from an ancient unit of weight or token. In Vulgate Latin (fourth century) *talentum* adopted, possibly for the first time, the meaning 'mental aptitude'. In the Middle Ages the term 'talent' took on the meaning of giftedness in the sense of inborn ability; this meaning persisted into the first half of this century (e.g. Révész as late as 1952). The concept of genius, long native to psychiatry (cf. Anastasi, 1958), can also be traced back to its classical roots (Heller, 1993b).

In a more narrow sense, research on the nature and nurture of the gifted began at the turn of the last century but has intensified and become increasingly more sophisticated, focused and informative in the last few decades. Americans tend to mark the beginning of serious research on the gifted with the 1922 initiation of Terman's so-called *Genetic Studies of Genius* when a life-span longitudinal study "was designed to discover what physical, mental and personality traits are characteristic of gifted children as a class and what sort of adult the typical gifted child becomes" (Terman & Oden, 1951, p. 21). Europeans sometimes cite William Stern's 1916 publication *Psychologische Begabungsforschung und Begabungsdiagnose* [Psychological research and detection of the gifted] as having preceded the Terman study and a better benchmark.

There were, of course, earlier studies about the nature of 'genius', the training and exploits of 'Wunderkinder' and other prodigies and the provisions made for rapid learners and academic achievers (see Chapters I, 7 and II, 8). The editor of a 1924 yearbook of the National Society for the Study of Education (NSSE) observed that:

Lombroso's *Man of genius* (1891), Galton's English *Men of science* (1874), Galton's *Hereditary genius* (1869), Constable's *Poverty and hereditary genius*

(1905), Cattell's *A statistical study of American men of science* (1906–1910) are characteristic studies that have helped define the problem of the origin of superior achievement, especially to raise the issue as to the relative contribution of inherited constitution and educational training in the production of greatness (Whipple, 1924, p. 2).

The 1924 NSSE yearbook entitled *The Education of Gifted Children* contains an annotated bibliography of 453 entries—mostly American although several German citations are included. The sheer volume provides clear evidence that there was considerable interest in the nature and education of the gifted in the early part of the last century. The content of the articles as reflected in the titles and annotations suggests that many of the topics discussed or reported were not unlike those one finds in more recent literature. There were articles on intelligence testing as a means of identification, descriptions of 'superior groups', comparisons of 'bright and dull pupils', honors plans, studies of precocious and 'super-normal' children, outcomes of ability grouping, the nature of genius and even a 1906 article by Terman titled 'Genius and stupidity'. (This was a report on his doctoral dissertation which he finished in 1905. In June 1905 he received his doctoral diploma from the hands of President Theodore Roosevelt.)

In his Editor's Preface to the 1924 NSSE yearbook, Whipple noted that the "Committee has not found itself in agreement upon some fundamental principles involved in the education of gifted children" (p. iv) including the various means "for the selection of gifted pupils or the administration of their training" (p. 24). These same two classes of issues persist.

#### *Themes and Issues from Earlier Research*

In 1960, in connection with legislation being considered by the State of Illinois, Gallagher prepared a report whose purpose was "to review and summarize all of the information now available relating to the education of gifted children" (p. 3). Gallagher summarized his findings under the following headings: identification, cultural background, intellectual patterns, academic achievement, social popularity, emotional adjustment, elementary programs and program evaluation. He concluded that a clear generalization that can be drawn from the review of research was that "special programming for gifted children requires additional personnel and services" (p. 131).

In 1963, Mönks published a review article entitled *Contributions to the study of giftedness in childhood and adolescence*. In this article a survey was made of the then existing trends in the study of gifted children and adolescents. Six theoretical approaches were identified and summarized as follows: (1) clinical approach or the theory of disharmony, (2) socio-

cultural/psychosocial approach, (3) psychoanalytical approach, (4) hereditary theory, (5) theory of differentiation and (6) theory of harmony (after Terman's correlation of giftedness with psychological and physical health). The same article proposed a longitudinal study to develop an empirical basis for the improvement of psychological educational as well as instructional guidance of gifted students (see Mönks, 1992).

About 40 years before the 1963 Mönks' article there already existed in the Netherlands scientific interest in the gifted child. The contribution of the Dutch psychologist Révész (Hungarian by origin, residing in Amsterdam after 1921) about a musical prodigy in 1925 is well known. Other psychologists like Waterink and De Groot contributed to the study of giftedness theoretically and empirically. But at that time (1938, 1956) policy makers were more interested in "equal opportunities for all" and this meant for the children with handicaps (see Mönks, 1992). Concern for the appropriate education of the gifted and interest in theoretical conceptualizations of giftedness have a long history in Europe but a minimal impact on research and practice. During the last decade of the 20th century, however, there is not only a growing awareness of the needs of gifted learners in almost all European countries (see Chapter VI, 4), but a substantial improvement of gifted education in schools and also expanding research activities in universities.

While many perennial research themes are still being studied, other topics are now the focus of investigation, often using more insightful or more sophisticated means to probe more meaningful questions. For example, Heller (1992, pp. 75–76) proposed the following research topics which seemed important to him in understanding talent and its nurture:

- Development of instructional concepts and pedagogy for the gifted.
- Curricular development for special academic courses, special classes or even special high schools for certain acceleration groups, for enrichment groups and for extracurricular support of the gifted—including evaluation of such courses and programs.
- The construction of identification instruments for process diagnosis or dynamic assessment (as a complement to the 'status diagnosis'), the testing of successive decision strategies and multidimensional classification models.
- Construction of area-specific counseling tests for talented adolescents.
- Longitudinal studies of the gifted including analyses of the living environment over the whole life span.
- Study of leisure-time activities of talented adolescents and their influence on personality development.
- Career problems of talented girls and women especially in the fields of mathematics, natural sciences and technology.

- Analyses of metacognition, causal attribution, achievement motivation, self control, heuristic skills, the self concept (including sex differences) and self-evaluation of abilities.
- Quasi-experimental intervention studies for counseling and supporting gifted children and adolescents.

### Definitions and Conceptions of Giftedness

A basic problem in building a theory about giftedness is that it is a multifaceted phenomenon, the nature of which is still at issue. Can a single theory account for the appearance of precocity as in 4-year olds who play chess or who write publishable poems or 10-year olds who are concert-class performers or children who perform exceptionally well on academic tasks or school-age children who develop patentable inventions? Put another way, can a single theory explain the rare Einsteins, Shakespeares, Nijinskys and similar talented individuals as well as the child whose 'giftedness' appears to be achieving unusually well academically as measured by standardized achievement tests?

Research and experience over the past decades have underscored the range and variety of individuals whom school personnel and different communities (e.g. cultural, artistic, business and industry) have identified and labeled 'gifted' or 'talented'. Depending on the criteria being applied, there are some children who are only slightly above average while others are so far above the average as to be extremely rare. In the U.S. A., the latter are sometimes called, only partly in jest, "severely and profoundly gifted." Some individuals seem to have talent potential in a single area while others appear to have potential in a variety of areas. Some individuals who have manifested talent potential seem to have little or no interest or motivation to develop or use that capacity while others are highly interested, motivated, committed and involved. Some youngsters are especially precocious, manifesting unusual talent potential at very early ages, while others are 'late bloomers' who do not show unusual potential or performance until much later in their development. There are youngsters who educators believe are academically gifted—i.e. high achievers, good test-takers, good designers and implementers of school projects—but who are not necessarily outstanding performers and producers outside the classroom. Some talent areas seem to be manifested earlier than others. Some 'academic absorbers' deal with their learnings in straightforward ways, while others seem to take delight in 'playing around' with ideas and challenges in creative and innovative ways.

Thus, the gifted and the talented are clearly a very heterogeneous set of persons and it is this multidimensional heterogeneity which may preclude a comprehensive theory. The absence of such a theory, however, does not prevent us from deepening our insights and understandings of the phenomena nor

intensifying efforts to identify talent potential and nurture talented performance.

*Giftedness* and *talent* are terms which have been variously defined over the years and a variety of conceptions have emerged related to these diverse definitions. Feldhusen & Jarwan (1993, pp. 234–235) suggested that definitions of giftedness can be classified into six categories: psychometric, trait, social needs orientated, educationally oriented, special talent and multidimensional (also see Chapter III, 1 in this handbook). Eysenck & Barrett (1993) viewed giftedness as a ‘fuzzy concept’ that can be defined in three major ways: “(1) as synonymous with *general intelligence*; (2) as synonymous with *creativity*; (3) as synonymous with *special (artistic or scientific) ability*.”

Renzulli (1982) has asserted that despite efforts throughout the century, “the precise definition of giftedness remains a question with no universally accepted answer” (p. 723). He suggests that the many definitions of gifted range along a continuum from a ‘conservative’ end represented by Terman’s definition of the top 1% in general intellectual ability to the more ‘liberal’ definition of Witty who recommended that the definition of giftedness be expanded to include any child “whose performance, in a potentially valuable line of human activity, is consistently remarkable.” Also see Chapter IV, 3 in this handbook.

Heller (1989) notes that “giftedness belongs to the class of so-called hypothetical ‘construct’ terms whose definition is dependent on the chosen theoretical frame of reference,” a term which “is strongly convoluted with relatively complex behavioral phenomena” (pp. 140–141). Gallagher & Courtright (1986) have argued that “one term, *gifted*, has been used to describe two different constructs . . . [which] “although overlapping, emerge from different traditions and have a number of subtle differences that create confusion and contradiction” (p. 93). One construct derives from the studies of psychological scientists on individual differences while the other “stems from educational practice and the need for schools to design special educational programs for students who possess abilities and perform far in excess of their age mates” (p. 93). Gallagher (see Chapter VI, 2) asserts that the educational definition of giftedness has significant policy implications with identification and program goals following from the constructs accepted.

In Sternberg & Davidson’s (1986) *Conceptions of giftedness*, some 17 different conceptions of the construct are presented and discussed by the persons who proposed and advanced them. These constructs, as Sternberg and Davidson put it, “although distinct, are interrelated in certain ways” (p. 3). They divide these different conceptions into those which are *implicit-theoretical*—each presenting “a somewhat different implicit theory of giftedness that seeks to define this elusive concept” (p. 4)—and those which are *explicit-*

*theoretical*—each emphasizing explicit theories of giftedness in terms of cognitive or developmental psychology. The different conceptions of giftedness are also divided between those which are school-centered and those which focus on adult performance and productive behavior.

An example of an implicit-theoretical conception is that of Tannenbaum (1983) who views the interaction of five factors resulting in gifted/talented performance. These include: (1) *general ability* or tested general intelligence with different threshold IQs being required for various kinds of accomplishment; (2) *special ability* or special capacities or affinities for various kinds of work; (3) *non-intellective factors*, a confluence of affective elements such as ego strength, persistence, delayed gratification, (4) *environmental factors* including “stimulating home, school and community settings [which] are indispensable not only for maximizing potentialities but also for helping to determine the directions they take” and (5) *chance factors*, “unpredictable events in a person’s life that are critical both to the realization of promise and to the demonstration of talents” (pp. 87–88).

Another example of clustering the different orientations and conceptions is the following: (1) trait oriented definitions, (2) cognitive component models, (3) achievement-oriented models and (4) socio-cultural/psychosocial oriented models (see Chapter II, 1). These models have to be seen as complementary since each of them emphasizes an important aspect.

Sternberg’s (1986) triarchic theory of intellectual giftedness is an example of an explicit-theoretical conception based on cognitive theory. This theory consists of three subtheories: The first “relates intelligence to the internal world of the individual, specifying the mental mechanisms that lead to more or less intelligent behavior”; the second “specifies those points along the continuum of one’s experience with tasks or situations that most critically involve the use of intelligence”; and the third relates intelligence to the individual’s external world, “specifying three classes of acts—environmental adaptation, selection and shaping—that characterize intelligent behavior in the everyday world” (p. 223).

Sternberg & Davidson (1986) see definitions of giftedness as having particular significance in identification and development:

Giftedness is something we invent, not something we discover. It is what one society or another wants it to be, and hence its conceptualization can change over time and place. If the definition of giftedness is a useful one, then it can lead to favorable consequences of many kinds, both for society and for individuals. If the definition of giftedness is not useful, valuable talents may be wasted, and less valuable ones fostered and encouraged. It is thus important for all of us to understand just what it is

we, and others, mean by the concept of *giftedness* (pp. 3–4).

Many different decisions regarding identification, education and counseling, for example, depend on the often only implicit conception and definition of giftedness. Therefore clarification of underlying constructs is essential for both program and research design.

Definitions, concepts and constructs which guide research and educational planning today are much more diverse, much more research and theory based and much more influential on the planning and program decisions being made for the identification and development of talent. At the beginning of 21st century, it would appear that efforts to develop better theories and conceptions of giftedness and talent in order to improve program and practice will continue but the focus will no longer be on devising a single, comprehensive conception or construct of giftedness and talent (Feldhusen, 1998; Benito & Moro, 1999). There is increasing recognition that theory building and conceptualization of the phenomena of giftedness have considerable significance in determining what should be done to bring giftedness potential to talent realization (see Chapters I, 3–4) or to develop high expertise and excellence in a specific domain (see Chapters II, 3–5).

### Developmental Issues

#### *Studying Giftedness from a Life-Span Perspective*

Charlotte Bühler, the pioneer of life-span psychology published in 1933 the groundbreaking book 'Der menschliche Lebenslauf als psychologisches Problem' [The human course of life as a psychological problem]. The life-span view in developmental psychology has its roots in Europe (Mönks & Spiel, 1994; see also Chapter II, 1 in this handbook). Only in the latter half of the 20th century human development was not longer seen as being synonymous with child and adolescent development. The traditional approach to human development emphasized extreme change from birth to adolescence, stability in adulthood, and decline in old age; e.g. the decrease of cognitive functioning has been discussed extensively in the literature under the heading 'deficit model'. According to the deficit view there is indeed a decrease of cognitive functioning from adulthood on. The age of onset lies somewhere between 20 and 40. If, however, a distinction is made between *fluid* and *crystallized* intelligence (cf. Cattell & Horn, 1978), the outcome is different. From longitudinal data one can draw the conclusion that there is no decline of *crystallized* intelligence with age, while the *fluid* intelligence decreases, indeed, beginning roughly at the age of 30 years. Furthermore, it is not age as such which has influence on cognitive functioning, more important is rather the amount and quality of academic training and health conditions. Age must be regarded as

an index of experiences and not as an independent variable which influences human behavior.

The life-span perspective has seven explicit characteristics (Baltes 1987; cf. Mönks & Spiel, 1994, pp. 137–138).

- (1) *Life-long development*: Development as a process of change takes place throughout the whole life.
- (2) *Multidimensionality*: Human development consists of different dimensions and a variety of components within these dimensions.
- (3) *Multidirectionality*: Some dimensions or components may increase, while others decrease.
- (4) *Plasticity*: Human development may take different paths, depending on the individual's life conditions.
- (5) *Historical embeddedness*: Development is influenced by historical as well as economical and cultural conditions.
- (6) *Contextualism*: The individual is responding to and acting on contexts; heredity is not a fate but is always heredity in a specific environment.
- (7) *Multidisciplinarity*: Human development needs to be studied in an interdisciplinary context.

The most famous life-span study is Terman's *Genetic Study of Genius* which started in the 20s and is still ongoing (Terman, 1925; Terman & Oden, 1951; Walberg et al., 1994). His 1528 subjects (672 girls and 856 boys) were selected on the basis of an IQ score of 135 or higher. His selection was based on IQ as the only crucial factor of giftedness. Actually, his selection was very careful and he did try to apply the high scientific standards of that time. In spite of the many deficits of such pioneering approach, his data provided us with rich material and new perspectives on the development of gifted subjects. Terman, convinced by his own empirical data, came to the conclusion that intelligence is important, a necessary condition, but that a supportive home and school environment as well as high achievement motivation contribute in an essential way to the realization of high potential.

It is evident that many researchers avoid longitudinal studies since it takes years to get data. At the time the data become available for interpretation, they may no longer be relevant for the new situation due to societal and cultural changes. But it is also evident that we need longitudinal studies to get insight into the development, i.e. changes over time, of gifted individuals (cf. Subotnik & Arnold, 1994). For recent longitudinal studies see e.g. Heller (1991, 1996, 2000), Rost (1993), Perleth & Heller (1994), Benbow & Lubinski (1996), Achter et al. (1999), Lubinski & Benbow (1994, 2000), and Chapter VI, 4 in this handbook. An effective approach seems to be the so called mixed longitudinal study according to Schaie's (1970, 1983) most efficient design. Studies of this kind could provide us with information on (Mönks & Spiel, 1994, p. 139):

- which conditions facilitate or hinder the development of gifted potential,
- whether there are 'typical' developmental processes characteristic for the gifted in comparison to the non-gifted,
- whether there are domain specific patterns of development in gifted individuals,
- whether there exists a relationship between creativity and giftedness or not, or to what extent,
- what the *g*-factor contributes to the cognitive development of gifted individuals and whether the *g*-factor shows stability and/or variability over the life-span or parts of the life-span.

These kinds of questions can only be solved when disciplinarity (e.g. behavior genetics) forms the guideline for research projects.

According to Subotnik & Arnold (1994; see also Chapter II, 9 in this handbook), future longitudinal studies should attend to the interactions between talented individuals and their field, by examining domains and fields over time, and by carefully specifying the definitions of eminence, genius, giftedness, or talent. A systems approach to longitudinal research offers three distinct advantages. First, this approach offers an empirical base on which to judge significant innovation in a domain. Second, it accounts for the social context of accomplishment. Third and finally, the person-domain-field conception focuses research on the products of greatest significance to our lives. Subotnik and Arnold argue that longitudinal studies of both everyday creative giftedness and creative eminence are valuable, complementary endeavors—one improves daily life in our homes and schools, the other can attune us to recognize, value, and develop talent with the potential to reach beyond the individual to the transformation of society.

#### *Expectations from Cross-Cultural Socialization Research*

Important advances in our knowledge about developmental conditions of gifted children and adolescents can also be expected from cross-cultural investigations in the field. This has thus far been somewhat neglected in the research of giftedness.

The reason for relatively few cross-cultural studies which can be referred to as more than international cooperations but also meet scientific methodology requirements, is not only the enormous cost but also specific methodological problems which frequently confound work and financial loads. One expects *cross-cultural* research approaches within giftedness to bring about an increase in knowledge with regard to various cultural influences on individual developmental and educational processes. This goal should be met by a specific research strategy. This means that cross-cultural psychology should be defined by research methods rather than by the object of research. A good

example here is the comparative study of Peters (1998) concerning the self-concept of gifted adolescents in China and the Netherlands.

Three types of comparison are relevant: (a) cross-national, (b) cross-cultural, (c) cross-societal. In this context the second, cross-cultural studies, is of interest. With regard to the cross-national view, e.g. see Wilgosh (1994).

Culturally caused behavioral differences in the individual development should be identified through the systematic comparison of psychological patterns obtained in different cultural conditions; equivalent measurement instruments must be employed. This is a major problem of cross-cultural research; on the basis of such research designs, universal assumptions can be examined in relevant developmental, educational, learning or instructional areas. This is a function which was already emphasized by Wilhelm Wundt in his psychology of different cultures over one hundred years ago. Thus, the so-called *etic* (from phonetic) approach starts with a universal hypothesis of human behavior and personality, e.g. intelligence, creativity or achievement motivation. In contrast, the so-called *emic* (from phonemic) approach looks at cultural socialization influences within specific cultures (cultural-relativity hypothesis). Newer ecopsychological models attempt to integrate concepts of 'emic' and 'etic'.

Cross-cultural studies can provide new recognitions about social-cultural developmental and nurturance conditions of the gifted solely from their change of the perspective. This could lead to greater variety in the support of developing giftedness and program ideas. Not only this but also tolerance toward foreign cultures is increased. The meeting of different cultures can also be supported by international conferences (for greater detail see Chapter IV, 15 in this handbook).

#### **Identification of Talent Potential**

The procedures and processes by which talent potential is measured have changed dramatically since Terman (1925) selected the 1528 subjects (see p. 837 above) for his life-long longitudinal study: "The standard set for inclusion in the group was 140 IQ for Binet-tested subjects and 135 for high school subjects selected on the basis of the Terman Group Test" (Terman & Oden, 1951, p. 22). High intelligence, as measured by an individual or group test, became the basis for both defining giftedness and identifying gifted individuals. For an overview see Chapters III, 1-4 in this handbook.

Sternberg (1993) has reviewed procedures for identifying alternative approaches to assessing intellectual potential, arguing that "'giftedness' can be viewed as quite broader than a high score on a conventional intelligence test" and that "there can be different sorts of tests within each metaphor, depending upon the particular theory within the metaphor that generates the

test.’ Concerning methodological problems cf. Hany (1993).

Feldhusen & Jarwan (1993) submitted that a sound identification system must deal with a number of issues: “(1) the rationale and goals, (2) defining the target population, (3) use of single or multiple criteria, (4) types of test performance, (5) criteria for test selection and (6) selection strategies” (for further information see Chapters III, 1 and VII, 1 in this handbook; also Mönks & Heller, 1994).

Operational definitions and conceptions of giftedness guide identification and program planning. As Renzulli (1982) has pointed out: “there are very few educators who cling to a ‘straight IQ’ definition or purely academic criteria for identifying giftedness. ‘Multiple talent’ and ‘multiple criteria’ are almost the bywords of the present day interest in the gifted” (p. 723). Also see Chapter IV, 3 in this handbook.

Depending on the definition of giftedness or talent, multiple sources of information about individual differences may include some or all of the following (Passow, 1985a, p. 2049):

- Evidence of general ability and/or multiple intelligences including group and individual intelligence tests.
- Evidence of scholastic achievement, including standardized tests of achievement and teacher grades.
- Evidence from ‘creativity’ measures, including standardized tests of creativity, divergent thinking and productive thinking.
- Nomination by teachers on various kinds of rating scales and checklists.
- Nomination by peers on various kinds of rating scales, inventories, check lists.
- Nomination by parents on various kinds of rating scales, inventories, check lists.
- Evidence of productivity through products of individuals such as writings, compositions, sculpture, science projects, reports and so on.
- Evidence of noncognitive behaviors—for example, work habits, task commitment, self-directedness, pride in accomplishment, etc.—on inventories, check lists and rating scales.
- Autobiography and self-nominations.
- Evidence from judgment by experts in various talent areas, such judgments based on student products and/or performances, especially in areas such as dramatics, graphic arts, and music.

In addition to relying more on student performance and products in the identification process, another significant development involves the design of environments or settings which provide opportunities for a larger number of students to engage in a self-identification process by participating in enrichment activities which enable them to demonstrate their capabilities and manifest their talent potential. Milgram (2000) demonstrated in a recent special issue of

the *Roeper Review* that the strategies and procedures of *talent identification* and *talent search* vary worldwide. Hence an international sharing of knowledge and experiences in this field could enlarge the research and practice of identifying and nurturing the gifted and talented.

Identification procedures have been seriously criticized for their failure to identify gifted in such populations as racial and ethnic minorities, the disadvantaged and poor and those with limited language in their land of residence. There are increasing numbers of such students not only from a given country itself but also those displaced by political and/or economic hardship. Increasing attention is being paid to procedures and techniques which will enlarge the talent pool from these seriously underrepresented populations. For dynamic assessment see Chapter III, 2; for early identification Chapter III, 3 in this handbook.

Three examples of such effort are *The National Research Center on the Gifted and Talented* at the University of Connecticut and the University of Georgia (USA), which is developing methods for identifying diverse populations and training teachers to recognize such giftedness; *The Center for the Study of Giftedness* at the University of Nijmegen (The Netherlands), where work is ongoing in identifying and providing enrichment for both minority students (primarily Turkish and Moroccan) and disadvantaged Dutch students; and the *Center for the Study of Excellence (CSE)* at the University of Munich (Germany), where the Munich High Ability Test Battery (MHBT)—consisting of two dozen scales—has been developed (Heller & Perleth, 2002).

In the year 2000, it would appear that the multi-dimensions of giftedness and the concept of multiple talents will prompt the design and employment of much more authentic and complex identification procedures; less reliance on single tests, particularly IQ tests; more design and dependence on self-identification wherein individuals can demonstrate their talent potential by their performances and products; much more use of enrichment curricular opportunities to provide the basis for manifestation of talent potential and increased efforts to identify talent potential among the many seriously underrepresented populations.

### Gifted Education

Perhaps the fundamental question educators of the gifted must deal with has always been and continues to be: What kinds of education and socialization opportunities and experiences are needed to transform talent potential into talented performance? See Chapters IV, 4 in this handbook.

More than four decades ago, pointing to the tendency to believe that if only children with talent potential could be identified then they could readily be

provided with appropriate experiences to nurture that talent, McClelland (1958) observed:

Suppose we could locate that sleepy boy in the back row, the potential poet; what would we do for him? Would we offer him a liberal scholarship to one of our better private schools? Would we 'enrich' his curriculum with special readings in poetry, or in the Greek classics? Or would we perhaps excuse him from school altogether on the ground that he would do better as a self-educated man? Or would we supply him with a vocational counselor who would help him find his real niche in life? . . . The plain fact is that we do not know what we would do; we do not know enough about what goes into the making of a poet . . . we still know far too little to be confident about how to develop talented performance out of talent potential (pp. 23–24).

While what goes into the making of a poet, a scientist, a painter, a musician, an orator or any other talent domain may not be known with the certainty that specific actions will result in nurturing particular giftedness, we do know that the absence of certain kinds of experiences will impede or thwart the realization of talent. For example, a strong case can be made that the 'potential poet' whose language is not cultivated and enriched, whose understanding of the beauty and esthetics of language is not nurtured, who has not experienced various genres of poetry, who has not acquired the connoisseurship that enables him/her to distinguish between 'good and bad' poetry, who has not had opportunities to produce poetry, who has not been encouraged to play around with words and ideas and who has not had opportunities to 'do poetry'—is not likely to transform his/her potential into superior performance. We do not know that the 'potential poet' will emerge but we are pretty certain that without these kinds of experiences and learning opportunities, he/she is very unlikely to become a gifted poet. The same arguments could be made for other areas of giftedness or talent.

Every area of specialized talent has a content and a substance, its very special methodologies and processes, its modes of problem definition and problem solving, its ways of exercising creativity, innovation and originality. A specialized curriculum for the gifted should activate and motivate the commitment and the development of the competencies and affective behaviors needed for nurturing one's special talent potential.

To be able to meet the learning and developmental needs of gifted students, appropriate teacher training is an imperative. So far, the education and instruction of gifted students have not been included in teacher training. Therefore post graduate training for teachers and/or inservice-training should have priority in order to increase the number of teachers as gifted education specialists. The ECHA diploma may serve as an

example for that, which has been established as *European Advanced Diploma in Educating the Gifted* in connection with the University of Nijmegen in 1994 (cf. Katzko, 1996, pp. 2–5).

#### *Curricular Programs and Provisions for the Gifted*

Educators planning for the gifted are concerned with designing educational settings and learning engagements that make available opportunities for students to acquire the knowledge, insights, skills, understandings, motivation, interest, values and other learning that will enable them to perform at levels of excellence that might be described as 'gifted' or 'talented'. Not every potential poet will emerge as a poet but it is unlikely that potential will be realized without appropriate experiences. It is the nature of 'appropriate experiences' that is at issue.

For more than a century schools have provided programs of various kinds aimed at nurturing the potential of gifted and talented children and youth. Practically every aspect of the educational process—the goals and objectives, curriculum content, instructional strategies, teaching/learning resources, personnel resources and evaluation and assessment programs—have been modified and adapted "to meet the needs of the gifted."

As the Marland Report (1971) put it, the gifted "are children who require differentiated educational programs and/or services beyond those normally provided by the regular school program in order to realize their contribution to self and society" (p. 2). The phrase "beyond those normally provided by the regular school program" implies that there is a curriculum which may be accelerated (experienced at an earlier age, in less time than is usual or at a more rapid pace), enriched (experienced in greater depth and/or breadth), or amplified (experienced beyond what is provided for other students, differing in nature or kind).

Programming for the gifted, i.e. the provision of differentiated curricula, raises a number of issues such as: Are there bodies of content and educational experiences that are essential for talent development? Is there a common body of curriculum content for all talent development? What kinds of specialized curricula are needed to nurture diverse talents? A curriculum and the instruction form the heart of any school system, thus also for gifted education. Because the "curriculum is *what* is taught to students, i.e. intended and unintended information, skills, and attitudes that are communicated to students in schools" (Sowell, 1996, p. 5), whereas the instruction is *how* the curriculum is delivered to students.

Are there education imperatives which are applicable to all gifted—i.e. are there learnings which are essential for all gifted and talented, regardless of their specific talent domain? Are there essential learnings

that all gifted must experience if they are to achieve maximum self-realization and fulfill their potential? Positions taken on these issues vary widely. Most curricular and instructional programs are based on a particular conception of giftedness albeit in most instances this is only implicit (see Chapters in Part IV, 1–15 and VI, 1–11).

There is a general consensus on the need for specialized curricula aimed at nurturing the diverse special areas of talent, providing learning engagements and opportunities that enable the individual to identify and develop the skills, knowledge, insights, understandings and values needed to realize one's area of specialized talent potential. The specialized curriculum starts the individual toward the development of his/her talent potential by activating and motivating the acquisition of and commitment to knowledge, skills and affective behaviors that contribute to talented performance (see Heller, 1999).

Not only are there issues concerning the nature of such specialized curricula but there are questions about the appropriate balance between the differentiated basic or general curriculum and the specialized curricula. Which subjects, which disciplines, which learning opportunities are appropriate at the early stages of talent development and how do these change as the talent matures and comes closer to the behaviors of a gifted adult performer? To what extent should the individual be permitted or encouraged to focus his/her learnings on a specific talent domain or to what extent should he/she be required to engage in basic/general or common learnings? Should the potential poet and the exceptionally able mathematician have opportunities to pursue more intensive study of creative writing or of advanced mathematics 'at the expense' of the general or basic education? These issues are essentially questions as to what constitutes a sound and appropriate general education which can serve as a foundation or base for the development of specialized talents and what comprises the specialized curricula.

A closely related issue of curricular balance is that of acceleration vis-a-vis enrichment—when and how to accelerate learning and when and how to enrich learning. For many years, literature on gifted education posed acceleration and enrichment as opposing concepts and the controversy still rages among some advocates of each process. Passow (1985b) has argued that acceleration “enables the student to deal with more advanced concepts at higher cognitive levels and thus represents an enriching experience” while providing opportunities for more advanced study in the area being accelerated or in another area or areas (p. 37). On the other hand, by providing “learning experiences that enable the student to probe more broadly or more intensively” using advanced resources “enabling gifted individuals to attain higher levels of insight, understanding, performance, or product development,” enrichment also involves acceleration (p. 37). For

further information see Chapters IV, 1–4 in this handbook.

Both acceleration and enrichment have qualitative as well as quantitative dimensions which make it possible for gifted individuals to pursue differential experiences through a greater variety of opportunities and engagements. Thus, the issue is now beginning to be reformulated, not in terms of acceleration vs. enrichment, but rather as the question: *When* is it more appropriate to alter the tempo or pace of instruction and learning and *when* is it more appropriate to alter the breadth or depth of experience and *how* shall this be accomplished?

During the past decades, mainly in the USA, there has been a proliferation of systems and models for designing programs for the gifted and talented (Fox, 1979; Maker, 1982; Renzulli, 1986; Renzulli & Reis, 1997). These models may focus on organizing for instruction (i.e. administrative models) or “consist of principles that guide the instructional process and give direction to the content, thinking processes and outcomes of learning experiences” (Renzulli, 1986). Maker (1982) observed that these models differ in terms of the theoretical assumptions made, “both regarding the nature of the learner (for example, learning, motivation, intellectual and emotional characteristics) and the nature or effectiveness of certain teaching methods” (p. 2). See also Heller & Hany (1996).

Some ideas of the diverse foci, nature and comprehensiveness of the models and systems that are currently being implemented in the USA can be gathered from the following listing (for greater detail see Chapters VI, 1 and 2 in this handbook):

- SMPY's model for teaching mathematically precocious students.
- The Autonomous Learner Model for the gifted and talented.
- The Integrative Education Model.
- The Learning Enrichment Service (LES): A participatory model for gifted adolescents.
- The Purdue Three-Stage Enrichment Model for Gifted Education at the Elementary Level.
- The Purdue Secondary Model for Gifted and Talented Youth.
- The Grid: A model to construct differentiated curricula for the gifted.
- The SOI System for Gifted Education.
- The Enrichment Triad/Revolving Door Model: A schoolwide plan for the development of creative productivity (see Chapter IV, 3).
- The Secondary Triad Model.
- Cultivating simultaneous student growth in both multiple creative talents and knowledge.
- Talents unlimited: Applying the multiple talent approach in mainstream and gifted programs.
- The Enrichment Matrix Model.

- Fostering effective independent learning through individualized programming.
- The Cognitive-Affective Interaction Model for Enriching Gifted Programs.
- The cognitive and affective taxonomies.
- The basic structure of a discipline.
- Discussions of moral dilemmas.
- Creative problem solving.
- Teaching Strategies Programs (Maker, 1982; Renzulli, 1986; Gallagher & Gallagher, 1994; Heller & Hany, 1996; Gallagher, 1997; Renzulli & Reis, 1997; Heller, 1999).

A criticism made of many of these models is that, with very few exceptions, they fail to deal with the total curricular experience and usually consider only one aspect of instruction and learning—whether to select and implement a particular system or model depends on the congruence between the conception and assumptions underlying the model and the particular goals of the school's program.

In the early 1920s the reform movement had a great impact on reshaping instructional and educational methods in schools. According to this movement education should be child centered. One of the most prominent reformers was Maria Montessori. Her educational system has been and continues to be a great help in optimizing individual development. Montessori education, like other individualized programs (Jenaplan, Daltonplan), has never explicitly formulated a gifted program. But in reality Montessori education realizes the core principles of gifted education: The level and pace of individual ability determines the content and speed of the individual student. These 'hidden' gifted programs should be made explicit and be made better known to parents and teachers.

Another issue regarding a curriculum for the gifted is that of the balance between cognitive and affective development. Most of the focus of curriculum design for the gifted is on cognitive development: the stimulation of problem-solving and thinking skills and academic and intellectual growth. Far less attention is given to the affective development of the gifted (the feelings, values, motivation, attitudes, morality, self-concepts) although some of the models mentioned above do attend to this domain (Dixon, Meyer & Hardy, 1986). Only a few models—e.g. Williams' (1986) Cognitive-Affective Interaction and Betts' (1986) Autonomous Learner Model for the Gifted and Talented—have the affective domain as a major focus. See Chapters II, 5–6 in this handbook. Passow (1992, p. 224) has observed that:

Regardless of their specific interests or degree of talent, a [curriculum] should foster self-direction and independence, intellectual and emotional self-reliance, self-set goals and a love of learning. It should stimulate a desire to create and experiment with ideas and things. It should nurture an understanding

and appreciation of one's cultural heritage. It should cultivate what Brandwein (1955) describes as persistence—a willingness "to labor beyond a prescribed time . . . to withstand discomfort . . . to face failure" (p. 10) and questing—"a dissatisfaction with present explanations of aspects of reality" (p. 11).

The processes of nurturing the affective development of the gifted has several dimensions: instructional, counseling and environmental. From a curricular and instructional perspective, every discipline or subject has the potential for enhancing affective growth through self-awareness, sensitivity to others, understanding, empathy, esthetic appreciation, interpersonal understandings and moral values (see Chapters IV, 9–10). From the counseling perspective, gifted and talented students face particular affective problems of a personal and interpersonal nature for which guidance and support are needed. From the environmental perspective, classroom, school and community climates are powerful influences on student behavior and learning, especially on affective development: self-concepts, attitudes, motivations, task commitment. As educators of the gifted have become more concerned with the affective dimensions nurturing talent, more attention is being given to curriculum, guidance and climate for learning, as these have an impact on affective development.

Still another dimension of curricular significance for the gifted focuses on interdisciplinary study. Curriculum content, Passow (1982) has suggested, should "include more elaborate, complex and in-depth study of major ideas, problems and themes that integrate knowledge with and across systems of thought" (p. 7). Curricula which are organized across themes or problem areas, using interdisciplinary approaches of a high order, drawing on knowledge and multidisciplinary resources appropriate to deriving understandings and gaining insights into those problems and themes are increasingly being perceived as germane to the education of the gifted (see Chapters IV, 1–2 and 12).

Another curricular issue focuses on the suitable balance between individual and group activity for the gifted. Independent study and individualized instruction are widely advocated for gifted students: opportunities to pursue their own interests, concerns, problems and preoccupations on their own and by themselves. On the other hand, in addition to the learning which come from interaction with students with a wide range of abilities, there is a good deal of research regarding the stimulation and exhilaration that come from interaction with other equally able gifted students. A differentiated curriculum for the gifted must provide opportunities for independent study as well as group learning activities depending on the particular goals and objectives being pursued. The request for individualized and differentiated curricula for the gifted is a realistic claim in accordance with

leading textbooks on curriculum. Sowell (1996) made a valuable distinction between: (a) curriculum conception, (b) purpose of education, and (c) primary source of content. He came to the following overview (cf. Table 1).

Dishart (1980) is critical of curricula which must be either enriched or accelerated in order to be used with the gifted and argues:

Educational programs for the gifted should be based upon the needs of the individual learners rather than upon making up for the program deficits in a curriculum for the non-gifted. There is a resultant difference between enriching or accelerating an inadequate and inappropriate curriculum and designing an adequate and appropriate curriculum for use in the first place (p. 26).

Educators of the gifted are taking heed of the concept of differentiated curricula which are "adequate and appropriate . . . in the first place." Educational planners are giving more thoughtful attention to the creation of a community of learners, to problems of sequence and articulation over the school years, to devising opportunities for individualized/independent study, to meaningful implementation of the concepts of acceleration and enrichment and to integrating curricular elements for the gifted within the total curriculum.

Moreover, increasingly planners are beginning to think in terms of curricula and learning experiences which extend beyond the classroom and into the community, using a broad array of relevant resources, both school and non-school. Mentorships and apprenticeships, for example, relate students with talent potential to talented adults who provide learning opportunities and serve as role models (Maaoz, 1993; Zorman, 1993).

There is, as yet, no certainty regarding appropriate and adequate curricula for the gifted but gradually the 'busy work' and 'fun-and-games' approaches to educating the gifted are being eliminated and there is increasing understanding and congruence between

operating concepts of giftedness, goals and objectives and the design of learning opportunities and learning environments (Van Tassel-Baska, 1998; Heller, 1999). For an international overview by country see Part VI of this handbook.

#### *Extracurricular Programs and Experiences*

Learning experiences outside school are often necessary and in any case very useful for the development of giftedness and talent, especially creative productivity. Because such individual activities are self-regulated learning processes, special interests are supported in an optimal way. Community facilities and opportunities for individualized leisure time activities are very important not only for the development of domain-specific competencies but also for the enhancement of self-concept and task commitment. Furthermore, leisure time activities offer chances for many relationships between gifted peers, which are important for the development of giftedness and talent. Therefore extracurricular programs like after school work groups, Saturday and summer programs or academies, academic olympiads, competitions, etc. provide gifted adolescents with a great variety of challenging experiences (see Chapter IV, 13 in this handbook).

Such learning opportunities are especially supportive for the development of gifted or talented girls and women (see Chapters V, 7–8). Inasmuch as the risk of limited socialization experiences, e.g. in the field of 'hard' sciences and technology, is quite higher for gifted/talented girls than boys, balancing leisure time activities are necessary for girls in such fields. An affiliated problem is the lower participation quota of girls in competitions in comparison to boys. Hence group competitions offer useful supplementary learning experiences for girls. Much research with respect to gender specific differences between gifted girls and boys and instructional approaches to cope with that problem has been carried out in recent years, in Germany e.g. Beerman, Heller & Menacher (1992), Heller & Ziegler (1996), Ziegler, Heller & Broome (1996), Ziegler & Heller (1998, 1999).

*Table 1. Curriculum Conceptions, Purposes of Education and Primary Sources of Content (according to Sowell, 1996, p. 41).*

Curriculum Conception	Purpose of Education	Primary Source of Content
Cumulative tradition of organized knowledge	To cultivate cognitive achievement and the intellect	Academic disciplines, subject matter
Social relevance-reconstruction	To prepare people for life in an unstable, changing world; to reform society	Needs of society and culture
Self-actualization	To develop individuals to their fullest potential	Needs and interests of learners

### *Community Agencies and Institutions*

As schools come to understand more about the nature of giftedness and its nurture, community agencies and institutions are being recognized as another essential element in talent development. Kough (1958) has argued that there are many specialized areas that schools can expose students to, but often they cannot provide the expertise needed for developing potential to a high level as well as a nonschool group can, and that "many of the educational functions which are directed by the schools can be enhanced by community activities" (p. 378).

Research and experience support the idea that education, socialization and enculturation take place in many different settings and that many agencies and institutions, besides the school, teach. A second important idea is that there are personnel and material resources in non-school agencies which can enrich the learning opportunities and thus challenge gifted and talented students far beyond that which the school can do (for greater detail see Maoz, 1993).

Community agencies and institutions often have far more appropriate, up-to-date and state-of-the-art equipment than that which the school can provide. Such agencies and institutions are not only sources for much needed materials and equipment but, equally if not more importantly, they are the places where practicing specialists—scientists, artists, musicians, researchers, artisans, technicians, media personnel, writers, government leaders, other professionals and other creative and productive individuals—are available who can serve as mentors, teachers and role models for young persons with talent potential.

Increasingly, the human and material resources of non-school individuals and groups are being used to extend educational opportunities and challenges for the gifted and talented. These resources are now recognized as not being simply enriching but, in many cases, they are absolutely essential and critical in talent nurturing efforts. A sound mentoring experience, for example, can have a significant impact on both the cognitive and affective growth of the child.

### *Administrative and Organizational Arrangements*

Curricula may be implemented and learning opportunities for the gifted may be provided in a variety of settings. These settings can be in or out of school, within regular classes, special classes or special schools, part-time or full time, beginning at and available in every grade level.

Special groups may be organized on the basis of ability, achievement, aptitude, interests or motivation and may involve students or the entire school population. Groups may meet for a few minutes a day or for the entire school day. The groups may be organized for a variety of purposes such as practice for debate or academic bowls, for drama or chess. Groups may include special classes or sections, special schools or

school-within-schools (e.g. the German Gymnasium with an eight year accelerated program in the regular nine year Gymnasium; cf. Heller, Osterrieder & Wystrychowski, 1995; Heller & Rindermann, 1999).

Despite the various kinds of grouping used in providing for the gifted, the general practice—usually called ability grouping or tracking—has a long and controversial history on philosophical, psychological, sociological and educational grounds. Because ability grouping has been an issue and been studied for almost a century, there is a considerable body of research available but the controversy is hardly resolved. In the United States, ability grouping/tracking has been linked to provisions for the gifted and, from time to time, has been condemned as 'elitist' and 'undemocratic', hindering both equity and excellence. Currently the U.S. pendulum is swinging away from ability grouping to cluster grouping (homogeneous achievement classes). For an overview of ability grouping vs. cooperative learning see Slavin (1992), Kulik & Kulik (1997), Robinson (1997, 1998), Van Tassel-Baska (1998), Gentry & Owen (1999); also cf. Chapters IV, 1 to 4, 12 and 13 in this handbook.

Some gifted programs do separate the gifted from other students but, except for full-time special classes or special schools, complete isolation is rare. Research has indicated that, depending on the circumstances, there are positive outcomes from the stimulation of gifted students interacting with each other and the competition as well as the cooperation that occurs in those settings.

Grouping and tracking are organization procedures intended to facilitate teaching and learning. What appears to be emerging is a consensus that the issue is not one of grouping vs. no grouping but rather one of *what kinds of grouping*—together with other elements of curriculum and instruction—are needed to foster optimum learning for all children, including those believed to have talent potential. A balance needs to be attained between learning experiences optimally engaged in with intellectual and creative peers and those that are best experienced with a broad mix of learners (Tannenbaum, 1998).

A variety of special schools for the gifted and talented, schools which usually have selected admissions and which provide distinctive domain specific learning opportunities, are still rare. Examples of such schools are the *Bronx High School of Science* (USA), *The Israel Academy of Arts and Science* (Israel) and the *Yehudi Menuhin Music School* (UK). In Europe there are many secondary schools for Dance, Music and the Fine Arts, or the *selective German Gymnasium*, eight year (instead of the regular nine year) accelerated program in Baden-Württemberg and Rhineland-Palatinate or several *private Gymnasias* in Germany, Austria and Switzerland. In the United States there has been a growth of residential Governor's schools which select students from entire states who are gifted in specific

areas: *The North Carolina High School for Mathematics and Science*, *The North Carolina School of Fine Arts*, *The Louisiana School for Arts, Science and the Performing Arts* and *The Illinois Math and Science Academy* exemplify such state supported selective special-purpose schools.

Despite the attainments of such schools as with other forms of grouping, they continue to be controversial. The basic argument advanced for their support is that they provide the kind of stimulating environment and appropriate personnel and material resources which are not possible in any other setting. The argument against such special schools is that they are elitist, undemocratic and use scarce resources needed by other less able students. Although the issue of special schools has never been resolved to the satisfaction of all due to deep philosophical and political differences regarding the extent that the student body is inclusive of minorities and disadvantaged gifted—i.e. the equity question is dealt with, special schools and special programs appear to be more acceptable.

At the beginning of the 21st century, it seems likely that the many controversies surrounding various kinds of administrative and organizational provisions will not be resolved, essentially because they are part of the larger issue of equity and excellence. Planners of programs for the gifted will need to draw on research for support of special provisions but use these insights in the context of planning rich opportunities for learning for all. See also Chapters V, 3 and 9.

### *Socio-Emotional Development, Counseling and Guidance*

Superior performance is determined by the interaction of many factors, cognitive, affective and social. The social and emotional issues, including self-concept can release or inhibit the full use of an individual's abilities (VanTassel-Baska, 1989; Freeman, 1991, 1997; Tannenbaum, 1998). How an individual functions cognitively is affected by and affects the individual's affective functioning—cognitive and affective systems are congruent and interactive. Tannenbaum (1983) argues that:

Ability alone cannot facilitate great accomplishment. It also requires a confluence of various non-intellective factors such as ego strength, dedication to a chosen field of productivity or performance, willingness to sacrifice short-term satisfactions for the sake of long-term accomplishment and many others. These traits are integral to the achieving personality regardless of the areas in which the talent manifests itself (p. 88).

Regardless of specific interests or degree of talent, opportunities are needed to foster such qualities as self-direction and independence, intellectual and emotional self-reliance, self-set goals and a love of learning, a desire to create and experiment with ideas and things—

all affective behaviors. Opportunities are needed to cultivate what Brandwein (1955) called *persistence* a willingness “to labor beyond a prescribed time . . . to withstand discomfort . . . to face failure” (p. 10)—and questing “a dissatisfaction with present explanations of aspects of reality” (p. 11).

As a group, gifted children tend to be more highly motivated, often have a strong desire for self-advancement and unusual emotional depth and intensity; they tend to have higher self-concepts and stronger ego strengths; are inclined to be greater risk-takers; tend to be more sensitive to the expectations and feelings of others; often express idealism and a sense of justice earlier and tend to be more independent, more forceful and more competitive.

By virtue of their being ‘different’, the gifted often encounter socio-emotional problems which can become serious. For example, sometimes, the gifted child's cognitive development far outstrips his/her affective development and adults expect equally ‘mature behavior’, creating problems by such expectations. Adult uncertainty about the nature of giftedness can result in their pressuring a child to conform or behave in particular ways or in their avoiding or ignoring recognition of unusual ability. Excesses in either direction can contribute to socio-emotional problems which require guidance and counseling.

Classroom curriculum and instruction can be boring and unchallenging or the classroom climate and school environment can influence student behavior and learning, positively or negatively.

Alan & Fox (1979) have categorized the affective problems of gifted children as environmental, interpersonal and intrapersonal. *Environmental* problems arise in a school setting where lack of a sufficiently interesting or challenging curriculum leaves the child feeling bored, resentful, hostile or disengaged. School problems arise when mediocrity is accepted, excellence is not recognized or rewarded and superior performance is denigrated or ignored. *Interpersonal* problems stem from the gifted child being perceived as ‘different’ by peers, teachers and adults whose consequent behavior may cause the gifted student to reject or deny his/her potential in order to become ‘more acceptable’. Interpersonal problems may also arise when parents, teachers, counselors and other adults have unrealistic expectations regarding the gifted child's performance and behavior. The gifted child's *intrapersonal* problems are those of self-concept, self-esteem and self-acceptance which can lead either to the development of appropriate coping strategies or dysfunctional behavioral responses.

In addition to these three classes of problems, the gifted child also faces problems of educational and career choice-decisions regarding higher education and professional pursuits stemming from their greater potential and higher achievements. All of these problems or potential problems call for guidance and

counseling which meets the particular needs of gifted children (see Chapters V, 3–6).

The still new history of the counseling of gifted students includes few publications (St Clair, 1989). Some of them are aimed at teachers, others at the students' parents. Some publications also focus on the personality of the individual looking for counseling. Need for counseling arises directly from giftedness or talent when, for example, there is an inappropriate interaction between the gifted child and the environment. Often age-related distributions of counseling needs specific to the gifted/talented can be found: These age-related problems are frequently confounded with gender-related socialization effects (Silverman, 1993, 1997; Colangelo, 1997; Kerr, 1997). Also see Chapters V, 7–8 in this handbook.

The task of counseling the gifted must be oriented toward individual needs and thus toward concrete counseling problems and at the same time toward the goal of optimal development of the student. In this sense, the counseling of adolescents is very important in supporting their identity formation. The essential importance of counseling in a sufficient program for gifted is emphasized by Silverman (1993). She reminds us that the development of gifted children is frequently asynchronous. Such uneven development leads to greater vulnerability for the gifted, especially for the highly gifted. Such children need counseling to assist them in dealing with their intense emotional lives, their heightened awareness and their difficulties in fitting in with age peers and rigid educational systems. Silverman postulates that the aim of counseling is not just the remediation of problems: Its main goal should be guidance toward self-actualization.

Those being served by counseling services for the gifted include also the gifted's parents, teachers and other important socialization agents including siblings and peers. Parents and teachers of the gifted often need

support because of the specific/unique needs of the gifted. Although scholastic counseling and individual psychological counseling are sometimes indistinguishable because of the inevitable overlapping of these two areas, they can be differentiated as follows (cf. Heller 1993a, 1996, 1999; Elbing & Heller, 1996):

- (1) *Scholastic counseling* includes problems of identification, nurturance or cognitive learning and achievement, appropriate classes as well as acceleration measures such as special schools, early admittance to school and skipping grades, extra-curricular enrichment activities and guidance toward appropriate post-secondary education.
- (2) In *individual counseling*, issues such as those listed in Table 2 are prominent.

One must always take the gifted individual's learning and thinking characteristics, interests and social-emotional needs into account (see Parts II, 4–8 and V, 1–6).

One should take the gifted's natural superiority in information processing into consideration when developing programs for the gifted in order to avoid boredom and loss of motivation. An extended period of non-challenging education frequently leads to later difficulties, usually when the task difficulty increases rapidly during secondary education and the gifted elementary school child has not learned how to learn, study or experience academic failure or frustration. For counseling and nurturing talented girls in particular see Chapter V, 8 in this handbook.

Counseling services also need to be appropriate and adequate for gifted students with learning disabilities and for those with physical handicaps. Counseling agents should also be trained to deal with populations too often underrepresented in gifted programming such as racial and ethnic minorities, the disadvantaged and those with limited language ability in their current land

Table 2. Percentual Frequencies<sup>a</sup> of Counseling Needs Specific to the Gifted from a German Gifted Counseling Center at the University of Munich (according to Heller, 1993a, p. 54).

Boys:	%	Girls:	%
(1) Search for nurturance possibilities	43.7	(1) Search for nurturance possibilities	54.5
(2) Academic achievement problems	31.3	(2) Identification of giftedness	45.5
(3) Identification of giftedness	31.0	(3) Educational counseling	24.2
(4) Boredom at school	22.3	(4) Skipping a class	21.2
(5) Doctor's recommendation	12.6	(5) Academic achievement problems	15.2
(6) Skipping a class	11.7	(6) Boredom at school	12.1
(7) Behaviour problems	11.7	(7) Doctor's recommendation	6.1
(8) Discrepancy between intellectual and social development	10.7	(8) Discrepancy between intellectual and social development	6.1
(9) Educational counseling	8.7	(9) Psychological problems	6.1
(10) Concentration problems	4.9	(10) Discrepancy between intellectual and motivational development	3.1

<sup>a</sup>Multiple listings possible

of residence. Increasingly, all over the world, perhaps especially in the United States and in Western Europe, there are students with the added psychological and/or economic handicaps that come from being uprooted from their original homeland. Additional counseling concerns are dealt with in Chapters V, 2–6 and 9.

An integrative model of counseling the gifted has been presented by Perleth & Heller (1992). The model explicates the necessity for cooperation between various counseling agents (school psychologists, school and vocational counselors, social workers, teachers of the gifted) and institutions (school, counseling agencies, research institutes) in order to meet the challenge of counseling the gifted and talented.

For this purpose, it is very important to strengthen the training of those involved in counseling students by including the area of giftedness in developmental, educational and clinical psychology. Counseling personnel should be able to identify and counsel gifted students. There is also a need for inservice counselor training programs (Milgram, 1991).

In the year 2000, it seems likely that increased attention to the mental health and affective development of the gifted will result in making available group and individual guidance and counseling appropriate to the particular needs of the gifted and talented. As educators become more sensitive to the affective characteristics and needs of the gifted, they will design and adopt educational, counseling and socializing experiences to meet those needs.

### **Creativity**

For some researchers, creativity is a basic component of giftedness, a characteristic or trait to be assessed in the process of identifying and selecting gifted and talented students. Some writers use the term as synonymous with giftedness. For others, creativity is a trait to be nurtured if talent potential is to become talented performance. Some researchers write of creative scientists, creative mathematicians or creative artists, for example. Others use the term creativity as synonymous with productive thinking, divergent thinking, critical thinking and even problem solving and view it as a quality to be stimulated and nurtured. For them creativity is more than intelligence and results from the synthesis of many brain functions.

A number of theories of the nature of creativity have been advanced—e.g. psychoanalytic, humanistic, personal attribute, developmental stage and right and left brain, to cite a few (cf. Tannenbaum, 1983; Gardner, 1993; Weisberg, 1993; Feldman, Csikszentmihalyi & Gardner, 1994; Hany, 1994; Milgram & Hong, 1994; Runco & Pritzler, 1999; Sternberg, 1999a). These theories attempt to explain the nature of creativity—some in terms of creative processes or abilities, others in terms of creative potential (see Chapters I, 5–7).

Research on creativity has focused on understanding its nature and functioning, on procedures for assessing

its nature and on ways of stimulating or nurturing it. Each focus has raised a number of issues. One perennial issue is the relation between intelligence and creativity—are they distinct and different or are they related and, if so, how? See Simonton (1988, 1999).

Guilford's work became, as Stein (1986) observed, "not only the starting point for those who study the intellect and those who wish to develop creativity tests, but it has also become a model for curriculum development." A social-psychological approach to education of creativity stems from Hennessey (1997); for providing creative school environments see Daniels (1997) and Chapters I, 5 and IV, 11 in this handbook.

A number of test batteries have been developed to identify creativity and these have been replete with controversy (Davis, 1997). One kind of problem has to deal with the validity of such tests. Tannenbaum (1983), for example, asserts that: "For a test to have good face validity, its content must resemble in some way the essential phenomenon it is measuring. This would be especially difficult to demonstrate in tests of creativity, considering the multidimensionality of the concept, how it develops in the human psyche and the mental processes involved in activating it" (p. 270). There have been a number of batteries of tests of creativity developed, and these have their supporters and their critics. While numerous studies have been carried out on many such batteries, as Tannenbaum notes, "from the research produced thus far, it is impossible to draw a clear picture about the relationships among tested creativity, IQ and achievement" (p. 293). Also see Heller (1989, 1991, 1992), Hany (1994).

Efforts to nurture creativity fall into two main categories: One is the development of a number of 'programs' for in-school or extracurricular use, and the second is the adaptation of the regular curriculum in order to stimulate the creative processes. Among the former, for example, are programs aimed at direct instruction to nurture creativity—such as the Meyers-Torrance Workbooks, the Purdue Creativity Training Program, Parne's Creative Problem Solving and Williams' Classroom Ideas for Encouraging Thinking and Feeling, to cite a few. Extracurricular programs are exemplified by the Future Problem-Solving Program and the Odyssey of the Mind, both national competitions designed to stimulate creativity. The latter involve a variety of instructional strategies—e.g. differentiated assignments, independent projects, real-life problems—which require students to deal with the regular curriculum in novel and innovative ways resulting in the stimulation of the creative processes. A basic issue posed is the extent to which these various school-centered curricula and activities actually stimulate creativity—however conceptualized and defined—and whether there is a carry-over to fulfillment of potential beyond the classroom. That is, are children who experience these programs and engage in these activ-

ities 'more creative' in their fields of endeavor as adults? Chapter IV, 11 in this handbook provides programs and strategies for nurturing creativity.

Clearly, issues concerning the assessment, identification and nurturing of creativity continue to involve both researchers and practitioners. In the coming years, it is likely that the theories and studies of creativity—its nature, assessment and nurture—will lead to a better understanding of the creative process and its relation to gifted and talented behaviors.

### Underachievement

A report by the *Fund for the Advancement of Education* (1957) framed the problem of underachievement as follows:

Despite the great strides made by American education over the last 50 years, we are still far short of the goal of enabling and encouraging every young person to develop his full potential. The resulting waste of rich human resources is enormous and is deeply rooted in our educational system, right down to the earliest grades. We must therefore attack the long-run problems of talent supply primarily through our school and colleges (p. i).

The phenomenon of underachievement is both a puzzling and a challenging one—puzzling in its complexities and challenging in the difficulty in reversing or overcoming it. Underachievement is essentially a school-centered concept—i.e. most definitions refer to a serious gap between predicted and actual school achievement. As Raph, Goldberg & Passow (1966) have noted: "The broadest definition of underachievement among the more able would refer to all those who, for whatever reasons, fail to develop their potentialities maximally. Only if it were possible to assess potential with sufficient accuracy to enable prediction of performance for all individuals would such a definition become operationally meaningful" (p. 2). Clearly, the accuracy of assessment and predictions has not reached that stage. Thus, Raph et al. (1966) suggested a much narrower definition of underachievement to include:

intellectual or academic ability on intelligence and aptitude tests but fail to develop their abilities . . . all those who rank in the upper third of the population in ability, but who do not graduate from high school, do not go on to college, or drop out of college before completing their studies, thus failing to acquire the academic preparation needed for the high level jobs they are potentially able to fill (p. 3).

Researchers and practitioners have used variations of this definition but almost all have focused on some variant of the discrepancy between actual attainment and expected attainment. Tannenbaum (1983) observes that "studies of underachievement show variations not only in symptoms but in etiology as well" (p. 224).

Explanations of the nature and causes of underachievement vary considerably. They include what Raph et al. (1966) called "phenomenological factors related to the underachiever's self-concept, self-ideal, motivation and adult models" (p. 181) as well as a variety of home and family factors such as parental pressures, expectations and attitudes as well as home climate and support (Butler-Por, 1987, 1993). Other researchers focus on school programs and classroom conditions as well as personality characteristics (Whitmore, 1980; Rimm, 1997; Supplee, 1990).

At the beginning of the third millennium, the seriousness of the phenomenon of achievement and its effects on individuals and society are being recognized and better understood. Because the probable causes of underachievement are so diverse, the identification strategies proposed for reversing it are diverse as well (Butler-Por, 1993; Ziegler, Dresel & Schober, 2000). Suggested intervention strategies include: changing the classroom climate to affect "the teacher's values, expectations, educational aims and her ability to establish accepting and supportive relationships between her and the children among the class members" (Butler-Por, 1987, p. 103); "systematic curriculum work in basic subjects" together with "stimulating curricula experiences" and curriculum enrichment (Butler-Por, 1987, pp. 108–109); focused counseling and guidance; and mentors and role models from the community and school. For further information see Chapter V, 5 in this handbook.

### *Underrepresented Populations: Gifted Minority and Disadvantaged*

Over the years, the under-representation of minority groups in programs for the gifted and in various fields of specialized talents has been a real concern for educators and society at large all over the world. The minority groups which have been of particular concern in the United States, include African Americans, Hispanic, Native Americans, Asian Americans and the disadvantaged—i.e. children who live in poverty. Research has not contradicted the belief that talent potential is actually equally distributed across lines of race, class and socioeconomic status (see Chapters V, 3 and 9 in this handbook).

As studies have shown, it is not simply a question of becoming "interested and acquiring a good education" but rather one of removing a variety of barriers to identifying and nurturing disadvantaged and minority gifted. Passow (1986, pp. 152–155) identified these barriers as including, but not limited to the following:

- Attitudes and expectations of educators who often do not believe there is giftedness in culturally different populations.
- Over-reliance on intelligence tests as the prime criterion for identification.

- A rigid learning environment and an inflexible curriculum which fail to take into account the individual needs and learning styles of these populations.
- Failure to provide the necessary general education, basic skills foundation and learning-how-to-learn skills which are required for the further development of specialized talents.
- Failure of the schools to understand the significance of a mother tongue other than English, denigrating language habits and speech patterns and failing to provide bilingual education where needed.
- Failure to create a learning environment and a climate for learning in which attention is given to both the affective and cognitive elements or talent development.
- Failure to select, assign and provide appropriate inservice education to teachers, counselors, administrators and other educators who must create the conditions for learning and who, by serving as the gatekeepers for programs and services are critical in talent development.
- Failure to help culturally different students enhance their self-esteem and recognize that systematic and longterm discrimination contributes to lower self-perceptions.

In countries around the world, there have been numerous programs aimed at increasing the participation of minority and disadvantaged populations in talent identification and talent development programs. These are generally focused on the perceived barriers and are aimed at using more appropriate multiple techniques and procedures in the identification processes, designing curricula and instructional strategies accelerating and enriching educational opportunities for underrepresented groups, providing appropriate counseling and other affective supports, rendering guidance to families and building support, involving community personnel as a way of extending resources and enlarging learning opportunities, developing culturally pluralistic, multicultural programs, creating a 'climate for excellence' in the school and community. Several countries have extended the school day and the school year in order to provide enrichment experiences.

In the United States, the *Jacob K. Javits Gifted and Talented Students Education Grants Program* provides financial support to help build a nationwide capability in meeting the special education needs of gifted and talented students in elementary and secondary schools. Since its passage in 1988, at least half of the appropriations have gone to proposals designed to serve gifted and talented students who are economically disadvantaged.

An outstanding example of serving such populations is the *Inanç High School* in Istanbul. This school—for academically gifted students from all parts of Turkey—

provides a free quality education for children between the ages of 11 and 18, who are economically disadvantaged.

Currently, there is a clear and widespread recognition that minorities and disadvantaged populations around the world represent the largest reservoir of undeveloped potential available and the identification and development of this talent potential has become especially apparent. The driving force behind the efforts to increase the representation of minorities and disadvantaged populations in the programs for the gifted is essentially one of achieving the twin goals of equity and excellence.

### Parents and Families

The family and parents constitute a child's first school. Research has shown that parents and families play a particularly important role in the development of the gifted child—especially in the affective domain, in the nurturing of self-concepts, values, attitudes, motivation, interests and commitment. For example, Bloom's (1985) study of 120 "'immensely talented' musicians, artists, athletes, mathematicians and scientists" found "strong evidence that no matter what the initial characteristics (or gifts) of the individuals, unless there is a long and intensive process of encouragement, nurturance, education and training, the individuals will not attain extreme levels of capability in these particular fields" (p. 3). Bloom found certain family values in all four talent groups studied: The value of achievement and the importance of doing one's best whatever the task was very important in the subject's homes. The parents' commitment to the productive use of time, the introduction of the child to the talent field, parental encouragement, the provision of resources and materials, and the arrangement of learning opportunities were very significant in the child's ultimate achievement. As Bloom and his colleagues concluded:

The parents' interest and participation in the child's learning contributed significantly to his or her achievement in the field. We find it difficult to imagine how these children could have gotten good teachers, learned to practice regularly and thoroughly and developed a value of and a commitment to achievement in the talent field without a great deal of parental guidance and support. The role of the home in supporting the long process of talent development is only one piece of the picture, but it is a crucial one (p. 476).

Parenting of gifted children involves many of the same issues, problems and challenges which arise in the parenting of any child—but much more. Fine (1977) has observed:

There is a need for parents to be very self-aware regarding their personal investments in the child and also to maintain an accurate and balanced perception of the child as a growing person. Gifted and creative children need parents for emotional support and encouragement, for value and behavioral guidance and to set realistic goals; it is appropriate and important that parents of gifted and creative children in fact do fulfill a parenting 'contract' with their children (p. 500).

Research has found that having a gifted child in the family affects relations among family members. Coleman (1985) has described the effects as follows:

The presence of a gifted child in a family can affect relationships among family members and their thoughts about their relationships. Changes are a product of the family rearranging itself to deal with a member who presents a behavioral pattern that departs from typical expectations . . . Once a child is suspected of being different, parental concerns begin to surface. These concerns become enhanced and even exaggerated as the differences between the gifted and other children become clearer and the parents feel the need to respond in some special way . . . The intrusion of official recognition by the school can create concerns for the family that were previously dormant or non-existent (p. 126).

Mentally and physically handicapped children have had strong advocacy for many years from their parents as well as from other concerned citizens. However, the gifted have a more recent and less effective advocacy. Parents and others who perceive the needs of gifted children have sometimes been hesitant to ask support for those who 'have it all'. Fortunately, parents have been aided by organizations such as the *National Association for Gifted Children* (NAGC) in the United States, the *European Council for High Ability* (ECHA), the *World Council for Gifted and Talented Children* (WCGT), parent organizations in several European countries and groups on the more local level—organizations who have developed programs of advocacy (Maier, 1993). NAGC, having a 50 year history, has developed a strong legislative branch and has obtained the attention and support of legislators. This support led to the *Jacob Javits Grant* which currently funds the *National Research Center* at four state university sites (see Renzulli & Gubbins, 1998, and Chapter I, 2). Parents are encouraged to participate in these local, regional, national and international organizations. Thus, parental concerns can be addressed, their understanding increased and their voices strengthened.

At the beginning of the year 2000, there is increased recognition that the identification of talent and its nurture is not a task which can be accomplished by the school alone. Research and experience have made clear

that parents and families are essential in the identification and fostering of giftedness but, just as the school cannot fully develop potential without the nurturance that takes place in the home, parents cannot play out their roles fully without the nurturance that occurs in the school. The role of parents and families in talent development is being acknowledged and studied. Increasingly, meaningful two-way communication channels are being established to facilitate mutual support between home and school. Counseling and advising services are being provided—not just the schools providing services to the parents and family but mutual interaction as parents provide information about the child from which the school can benefit as well (cf. Freeman, 1996, 1998, and Chapter V, 2 of this handbook).

### Needed Research and Related Topics

Finally, some state of the art consequences are formulated (for a general overview see Waldmann & Weinert, 1990). The following topics seem to be of the utmost importance for research on giftedness and talent (for greater detail see Heller, 1993b and c; in this handbook the Chapters I, 1 and 8):

- Increase in *basic research*: Cognitive science studies focusing on explanation of the nature of giftedness and talent are needed as a supplement to psychometric studies, which are indispensable to the prediction of excellence (see Chapters III, 2 and 4). Also longitudinal studies of giftedness are indispensable in uncovering causal explanations of intra- vs. interindividual differences in changes over the time and of the interactions of developmental variables (see Chapters II, 1, 7–10). Interdisciplinary research projects including neuro-psychological and biological approaches or genetic studies (see Chapter II, 2) as well as cross-national/cultural studies (see Chapter IV, 15) should continue to be intensified, especially to examine the generalizability or universal validity of many theories in the field. Quasi-experimental and qualitative studies are also increasing our understanding of the nature of giftedness and of developmental changes. Without such basic scientific findings, applied research will wither and the quality of gifted education will be affected in the near future. Additionally, ontological and meta-theoretical difficulties with conceptions of giftedness and talent must be considered (see Chapter I, 1).
- Deficiencies in *applied research*: Elaboration of multidimensional and multiple theory based identification strategies as well as dynamic assessment approaches to the diagnosis of giftedness (see Chapter III, 2) are needed for the practical tasks of gifted counseling, guidance and education. Further desired ends are the development of intervention programs—and prevention measures—for balancing gender-specific differences in cognitive abilities and

performances, especially in the fields of mathematics, 'hard' sciences and technology (see Chapters V, 7–8). Finally, new conceptions and methods of evaluating school and extracurricular programs are needed (see Chapter IV, 14).

There is a continuing evolution in the creativity programs from an emphasis primarily on divergent thinking in the 1950s and 1960s to models including a wide range of dynamic and expanding conceptions including critical thinking and varied abilities. Most creativity programs are still based on the older, limited models. Hence existing programs and curricular materials should be rethought in light of new concepts, such as Simonton's Chance Configuration Theory (1988a/b), or Sternberg's Investment Theory (Sternberg & Lubart, 1991) and social-environmental approaches (see Chapters I, 5–7). It seems especially important to revise one-sided training programs based on promotion of divergent thought processes which however neglect the mediation of knowledge (Weisberg, 1993). Investigations of the expertise-novice paradigm could provide useful information to domain-specific concepts of creativity and giftedness (see Chapters I, 3 and II, 3). Additionally the life-span approach to exceptionality and the study on late-life potential should be included in the study of creativity; see Simonton (1992, 1994, 1999a/b) and Chapter II, 10 of this handbook).

Last but not least, more interest needs to be dedicated to the evaluation of new gifted education programs and counseling or support measures. In connection with evaluation, problems arise concerning the qualification of teachers, counselors and other gifted education related personnel.

Real progress in knowledge, which provides a theoretical basis to practice, can be expected only in the long run. Thus, applied research can often serve only to optimize pragmatic procedures. More important is the demand for careful evaluation of concrete identification and effective gifted methods and curriculum. These measures, of course, always depend on value decisions and aims. These values should be explicitly taken into account in corresponding evaluation models (cf. Heller et al., 1995; Heller & Viek, 2000). Well planned evaluation can have the positive side-effect of bridging the often criticized gap between scientific research and educational practice (see Chapter IV, 14). Progress in knowledge from giftedness research is closely connected with material and personal resources.

Internationally these are quite differently distributed. In the USA and a few other countries there are basic training programs for future expert personnel in the field of gifted education (see Chapter V, 1). In Europe (Chapters VI, 1, 4–5) and in many other countries around the world (see Chapters VI, 6–11), inservice training programs dominate, e.g. for teachers and/or counselors. As far as we know, special gifted qualifica-

tion programs for scientific research personnel are very rare. Hence post-graduate (master or doctorate) programs are necessary for recruiting the ablest junior scientists into the field of giftedness research. Examples for that are the new international MA study program 'Psychology of Excellence' at the University of Munich (Germany), directed by K. A. Heller (*e-mail address*: heller@edupsy.uni-muenchen.de; *internet page*: <http://www.paed.uni-muenchen.de/excellence/>) or the postgraduate training program provided by the University of Nijmegen in cooperation with ECHA, directed by F. J. Mönks (cf. Katzko, 1996). Other examples are the MA study programs in Educational Psychology with a focus on Giftedness at the University of Virginia in Charlottesville (USA), directed by C. M. Callahan (*e-mail address*: cmc@virginia.edu) and the University of Calgary (Canada), directed by J. L. Lupart. Unquestionably, the scientific and practical outcome of giftedness research is highly dependent on the level of qualification of the scholars working in this area. In Table 3, the modules of the MA study program 'Psychology of Excellence' mentioned above are listed. This curriculum could serve as an example to the demands for qualifying practitioners (e.g. gifted educators and counselors) and researchers in the field.

On the other hand, "efforts to increase connections between studies of giftedness and mainstream psychological and educational research" (Jackson, 1993, p. 46) are necessary, because most mainstream researchers ignore or pay little attention to gifted journals (see Chapter I, 8 in this handbook). "However, studies of giftedness have contributed to mainstream theory and may play some special roles in theory development. Strategies for overcoming barriers to further integration with mainstream research are proposed" (Jackson, 1993, pp. 46–50).

## Conclusion

As we entered the third millennium, there are important advances to anticipate challenging tasks in gifted education and giftedness research. Most significant are the increasing tendencies toward interdisciplinary communication in research and practice, cross-cultural research and sharing of conceptions and practices and the continued tendency to perceive giftedness from a developmental perspective. There is evidence of evolving interdependence of research and practice, and we continue to press for greater understanding and awareness of giftedness by highly trained researchers.

The emergence of interdisciplinary approaches to the study of giftedness and related fields is a strong and promising trend. In reflection of a new world order there is increasing cross-cultural research and shared understanding. Internationally there is an increasing awareness of the special needs of gifted students and broader understanding of identification methods. Thus, this handbook may enhance the exchange of information and experience of researchers and practitioners

both in the gifted field and in the overall educational field. With encouraged and enlightened teachers, administrators, psychological advisors and counselors as well as parents, gifted young people will more probably be enabled to develop fully their potential and their own contributions to the world.

Table 3. Curriculum (Module Structure) of the International Two Year MA Study Program "Psychology of Excellence" at the LMU in Munich, Germany.

---

**Module 1: Excellence: Models, Research, and Development**

- 1a Conceptions of Excellence (obligatory) (3 hrs)
- 1b Cognitive Aspects of Excellence (2 hrs)
- 1c Motivational Aspects of Excellence (2 hrs)

**Module 2: Identification and Programming**

- 2a Models of Gifted Education (obligatory) (3 hrs)
- 2b Identification and Talent Search (2 hrs)
- 2c Promoting Excellence in School: Nurturing Strategies and Programs (2 hrs)
- 2d Promoting Excellence in the Corporate World (Business and Industry) (2 hrs)

**Module 3: Educational Psychology**

- 3a Introduction to Learning and Instruction (obligatory) (3 hrs)
- 3b Instructional Design (3 hrs)
- 3c Learning Environments and Educational Technology (3 hrs)
- 3d Self-regulated Learning, Metacognition, and Discovery (3 hrs)
- 3e Communication and Cooperation (3 hrs)

**Module 4: Differential Psychology**

- 4a Personality Psychology (obligatory) (2 hrs)
- 4b Diagnosis of Giftedness and Counseling Psychology (2 hrs)
- 4c Gender and Cross-Cultural Studies (2 hrs)

**Module 5: Research and Evaluation**

- 5a Research Design and Program Evaluation (obligatory) (3 hrs)
- 5b Advanced Statistics (obligatory) (3 hrs)
- 5c Research Practice I (obligatory) (3 hrs)
- 5d Research Practice II (3 hrs)

**Module 6: Social and Organizational Psychology (three obligatory)**

- 6a Center of Excellence (2 hrs)
- 6b Quality Management (2 hrs)
- 6c Career Development in Higher Education and in the Corporate World (2 hrs)
- 6d Career Counseling (2 hrs)
- 6e Leadership (2 hrs)

Students focusing on "Psychology of Excellence" with the **major in Educational & Differential Psychology** and the **first minor in Social & Organizational Psychology** (Modules 1 through 6) must choose **one of the following three modules** (7-1, 7-2, 7-3) to accomplish the requirements **for the second Minor**. In the chosen module three classes are obligatory. The program is taught entirely in English and includes **two internships** (consisting of six weeks each).

**Module 7-1: Science Education (all obligatory)**

- 7-1a Introduction to Science Education (2 hrs)
- 7-1b Physics Education (2 hrs)
- 7-1c Didactics in another subject (2 hrs)

**Module 7-2: Philosophy (all obligatory)**

- 7-2a Philosophy of Science (2 hrs)
- 7-2b Philosophy of Mind (2 hrs)
- 7-2c Corporate Ethics (2 hrs)

**Module 7-3: Sociology (all obligatory)**

- 7-3a Introduction to Sociology (2 hrs)
  - 7-3b Family and Kinship Systems (2 hrs)
  - 7-3c Comparative Religions (2 hrs)
-

# List of Contributors

Contributors are listed in alphabetical order together with their affiliations. Titles of articles which they have written follow in alphabetical order, along with the respective page numbers. Co-authorship is indicated by \*.

Ambrose, D. (Rider University, Lawrenceville, NJ, USA)

\**Conceptual Foundations and Theoretical Lenses for the Diversity of Giftedness and Talent*: 331

Andreani, O. (Istituto di Psicologia, Università di Pavia, Italy)

\**New Trends in Research on Moral Development in the Gifted*: 467

Arnold, K. (Boston College, USA)

\**Addressing the Most Challenging Questions in Gifted Education and Psychology: A Role Best Suited to Longitudinal Research*: 243

Assouline, S. G. (The Connie Belin & Jacqueline N. Blank International Center for Gifted Education and Talent Development, University of Iowa, Iowa City, USA)

\**Counseling Gifted Students*: 595

Baldwin, A. Y. (University of Connecticut, USA)

\**Global Professionalism and Perceptions of Teachers of the Gifted*: 565

Balogh, L. (Kossuth Lajos University, Debrecen, Hungary)

\**Gifted Education in Europe: Programs, Practices, and Current Research*: 703

Benbow, C. P. (Vanderbilt University, USA)

\**Gender Differences in Engineering and the Physical Sciences Among the Gifted: An Inorganic-Organic Distinction*: 633

Blumen-Pardo, S. (Catholic University of Peru, Lima, Peru)

\**Programs and Practices for Identifying and Nurturing Giftedness and Talent in Latin American Countries*: 817

Borland, J. H. (Teachers College, Columbia University, USA)

\**Identifying and Educating Poor and Under-Represented Gifted Students*: 587

Braggett, E. J. (Charles Sturt University, New South Wales, Australia)

\**Programs and Practices for Identifying and Nurturing Giftedness and Talent in Australia and New Zealand*: 779

Callahan, C. M. (University of Virginia, Charlottesville, Virginia, USA)

*Evaluation as a Critical Component of Program Development and Implementation*: 537

Campbell, J. R. (St. John's University, Jamaica, New York, USA)

\**Academic Competitions and Programs Designed to Challenge the Exceptionally Talented*: 523

Castellanos, F. X. (National Institute of Mental Health, Bethesda, Maryland, USA)

\**Attention-Deficit/Hyperactivity Disorder in Gifted Students*: 621

Castellanos-Simons, D. (Pedagogical University Enrique J. Varona, Havana, Cuba)

\**Programs and Practices for Identifying and Nurturing Giftedness and Talent in Latin American Countries*: 817

Cho, S. (Korean Educational Development Institute, Seoul, Korea)

\**Programs and Practices for Identifying and Nurturing Giftedness and Talent in Asia (outside the Mainland of China)*: 765
